FREEZING *Mixtures*. In proſecuting chemical and other inquiries, it is ſometimes requiſite to ſubject bodies to a greater degree of cold than the ordinary changes of temperature in the atmoſphere allow. A reduction of temperature is effected by the chemical union of certain bodies; or, to ſpeak more properly, by the ſolution of one body in another. Salts diſſolved in water, ice or ſnow diſſolved in nitric and muriatic acids, reduce the temperature of the mixtures a great number of degrees. The cauſe is, the mixture has a larger capacity for heat than would be derived from blending the two capacities of the ingredients, and taking a mean; but this ſubject will be diſcuſſed more properly under the heads of CALORIC, HEAT, &c.

Fahrenheit ſeems to have been the firſt who made any number of experiments directed to this point. The zero of his thermometrical ſcale is derived from the cold which a mixture of equal parts of ſnow and common ſalt produces; and his 32°, or freezing point, is the temperature of a mixture of ice or ſnow and water. Mr. Walker of Oxford has proſecuted this inveſtigation farther than any other perſon. The reſults of his experience are given in two papers in the Philoſophical Tranſactions for 1795 and 1801. One principal object he had in view, was to exhibit the congelation of quickſilver without great natural cold. He ſucceeded ſo far as to freeze it even in the ſummer, though it requires the temperature of — 39° at leaſt to congeal that metal. Profeſſor Lowitz of Peterſburgh, in 1796, publiſhed ſome intereſting experiments on the ſubject of frigorific mixtures, which may be ſeen in the Annales de Chimie, tome 22, for 1797. Fourcroy, Vauquelin, and Guyton, gave memoirs on the effects of frigorific mixtures in the 29th volume of the ſame work, which contains many facts deſerving attention. Lowitz's great improvement was in the introduction of muriate of lime, an article which unites almoſt all the deſirable properties of an ingredient in ſuch mixtures. It produces the greateſt degree of cold, is cheap in the firſt inſtance, and eaſily recovered for further uſe, and is not coroſive. By means of this article and ſnow, or pounded ice, very large quantities of mercury have been frozen. In 1793 Lowitz froze 12lbs. of mercury at Peterſburgh; and in 1799 Mr. W. H. Pepys of London, aſſiſted by ſome philoſophical acquaintance, froze 56lbs. of mercury; an account of which may be ſeen in the 3d vol. of the Philoſophical Magazine. Mercury in freezing aſſumes the cryſtalline form, and contracts in its dimenſions, according to Mr. Cavendiſh, $\frac{1}{23}$d of its volume, but according to Mr. Biddle, it amounts to $\frac{1}{7}$th of the volume.

The following table gives the moſt complete and accurate liſt of freezing mixtures and their effects, that we yet have. They are the reſults of Mr. Walker's experience.

Table of Freezing Mixtures.

Mixtures.			Thermometer ſinks
Muriate of ammonia	5 parts		From 50° to 10°.
Nitre	5		
Water	16		
Muriate of ammonia	5 parts		From 50° to 4°.
Nitre	5		
Sulphate of ſoda	8		
Water	16		
Nitrate of ammonia	1 part		From 50° to 4°.
Water	1		
Nitrate of ammonia	1 part		From 50° to — 7°.
Carbonate of ſoda	1		
Water	1		
Sulphate of ſoda	3 parts		From 50° to — 3°.
Diluted nitric acid	2		
Sulphate of ſoda	6 parts		From 50° to — 10°.
Muriate of ammonia	4		
Nitre	2		
Diluted nitric acid	4		
Sulphate of ſoda	6 parts		From 50° to — 14°.
Nitrate of ammonia	5		
Diluted nitric acid	4		
Phoſphate of ſoda	9 parts		From 50° to — 12°.
Diluted nitric acid	4		
Phoſphate of ſoda	9 parts		From 50° to — 21°.
Nitrate of ammonia	6		
Diluted nitric acid	4		
Sulphate of ſoda	8 parts		From 50° to — 0°.
Muriatic acid	5		

Sulphate

Mixtures.		Thermometer ſinks
Sulphate of ſoda -	5 parts	From 50° to 3°.
Diluted ſulphuric acid	4	
Snow - - -	1 part	From 32° to 0°.
Common ſalt - -	1	
Muriate of lime -	3 parts	From 32° to — 50°.
Snow - - -	2	
Potaſh - - -	4 parts	From 32° to — 51°.
Snow - - -	3	
Snow - - - -	1 part	From — 20° to — 60°.
Dilated ſulphuric acid	1	
Snow or pounded ice -	2 parts	From 0° to — 5°.
Common ſalt - -	1	
Snow - - -	3 parts	From 0° to — 46°.
Diluted nitric acid -	2	
Muriate of lime -	2 parts	From 0° to — 66°.
Snow - - -	1	
Snow or pounded ice -	1 part	From — 5° to — 18°.
Common ſalt - -	5	
Muriate of ammonia and nitre - - -	5	
Snow - - -	2 parts	From — 10° to — 56°.
Diluted ſulphuric acid	1	
Diluted nitric acid -	1	
Snow or pounded ice -	12 parts	From — 18° to — 25°.
Common ſalt - -	5	
Nitrate of ammonia -	5	
Muriate of lime -	3 parts	From — 40° to — 73°.
Snow - - -	1	
Diluted ſulphuric acid	10 parts	From — 68° to — 91°.
Snow - - -	8	

For more particulars in regard to the hiſtory of the congelation of mercury, ſee MERCURY.

A little experience will ſuggeſt ſome of the precautions neceſſary to enſure ſucceſs in theſe mixtures. The ſalts ſhould be cryſtallized, but reduced to a fine powder. The water of cryſtallization, probably exiſting in a ſtate reſembling ice, ſeems to perform an important part of the cooling effect. It is therefore needful that ſalts liable to effervescence, ſuch as the ſulphate and phoſphate of ſoda, ſhould be freſh cryſtallized, or kept from the action of the air; the muriate of lime, and other deliqueſcent ſalts, ſhould be cryſtallized, then pulverized, paſſed through a ſieve, and bottled cloſe, to prevent the acceſs of air. Mr. Walker informs us that muriate of lime of 1.45 ſpecific gravity will cryſtallize at the temperature of 32°, and is therefore beſt to uſe for that temperature; but for uſe in warm weather, he recommends boiling the liquid down to 1.49 ſpecific gravity at the temperature of 80°, cryſtallizing, pounding, and bottling, &c. The veſſels containing the frigorific mixtures ſhould be thin, and juſt large enough to hold them. Tinned iron will do well where no acids are employed. The ingredients ſhould be mixed as quickly as poſſible. When great cold is to be produced, the ingredients are to be ſeparately cooled in other freezing mixtures; thus they may be reduced to 0° by a mixture of ſnow and common ſalt. The thermometers uſed on theſe occaſions are made of ſpirit of wine or alcohol. The potaſh in the above table is cauſtic potaſh cryſtallized; and the diluted acids are the common acids of the ſhops diluted with equal weights of water. It is to be regretted that Mr. Walker has not rather given us the ſpecific gravities of the ſeveral acids uſed, as their ſtrengths as articles of commerce are known to be variable.

The beſt and moſt convenient of the above mixtures, when great frigorific effects are to be produced, is muriate of lime and ſnow. But when a reduction of 15° or 20° of temperature is only wanted, equal parts of nitre and ſal ammoniac, in the proper proportion of water, are found moſt advantageous, as the ſalts are eaſily recovered by evaporation.

It is remarkable that none of the above mixtures reduces the temperature of the ingredients above 83°. But in mixtures producing heat or increaſe of temperature, we have an elevation of 200° by ſulphuric acid and water mixed in due proportion; and a ſtill greater elevation is obſerved in mixing lime and water. This would ſeem to indicate that our preſent method of reckoning degrees of temperature is probably wrong; that the lower degrees are much too large, and conſequently too few in number. If the idea of Mr. Dalton be confirmed, that the freezing point of mercury at — 39° or — 40° of our thermometer, that is, at 72 below the freezing point of water, be really 200° below the ſaid point, when the degrees are duly appreciated, this remarkable circumſtance, of leſs cold than heat being obtained from chemical mixtures, will vaniſh.

FREEZING *Apparatus*, is a very ſmall apparatus contrived by Mr. Cavallo for freezing a ſmall quantity of water, *viz.* about 10 grains, in every climate. The whole apparatus is contained in a box 4½ inches long, 2 inches broad, and 1½ deep. The apparatus, and method of uſing it, are repreſented in *Plate* XIV. *Pneumatics*, *fig.* 8. E F G is a common phial with a glaſs ſtopple, filled with ether; E D is a glaſs tube with a capillary aperture at D, and having ſome thread wound round the other extremity for the purpoſe of fitting the neck of the bottle when the experiment is to be performed. A B is a glaſs tube about four inches long, and about ⅕th of an inch in diameter, hermetically cloſed at B. Into this tube a ſlender wire H is introduced, the lower extremity of which is ſhaped into a ſpiral, and ſerves to draw out the ice when formed. When a little water, C B, is put into the tube, the operator holds the tube by its upper part, with the fingers of the left hand, and keeps it continually, but gently, turning round its axis, firſt one way, and then the other; whilſt with the right hand he holds the phial in ſuch a manner as to direct the ſtream of ether, which comes out of the capillary aperture D, towards the outſide of the tube, a little above the ſurface of the water within. The ſtream of ether ſhould be ſuch as that a drop of it may, now and then, (*e. g.* every ten ſeconds) fall from the under part of the thermometer. By continuing this operation during two or three minutes, the water C B will be frozen, and may be drawn out of the tube in one hard lump of ice. When this is done, the phial is turned with its aperture upwards, the ſhort tube E D is removed, the ſtopple is placed in its ſtead, and the remaining ether is preſerved for other trials.

FREEZING *Rain*, or *Raining Ice*, is a very uncommon kind of ſhower, which fell in the weſt of England, in December, anno 1672. See Phil. Tranſ. N° 90.

This rain, as ſoon as it touched any thing above ground, as a bough, or the like, immediately ſettled into ice; and, by multiplying and enlarging the icicles, it broke all down with its weight. The rain that fell on the ſnow immediately froze into ice, without ſinking in the ſnow at all.

It made an incredible deſtruction of trees, beyond any thing

in

in all hiſtory. "Had it concluded with ſome guſt of wind," ſays a gentleman on the ſpot, "it might have been of terrible conſequence."

"The ſprig of an aſh-tree, of juſt three quarters of a pound, being weighed, the ice thereon weighed ſixteen pounds. Some were frighted with the noiſe in the air; till they diſcerned it was the clatter of boughs daſhed againſt each other." Dr. Beale obſerves, that there was no conſiderable froſt obſerved on the ground during the whole; whence he concludes, that a froſt may be very fierce and dangerous on the tops of ſome hills; while, in other places, it keeps at two, three, or four feet diſtance above the ground, rivers, lakes, &c. and may wander about, very furiouſly in ſome places, and be remiſs in others, not far off. This froſt was followed by glowing heats, and a wonderful forwardneſs of vegetation.

FREEZING *of Wines*. See *Condenſing of* WINES.

FREEZING, in *Commerce* and *Manufactures*. See FRIZING.

FREEZING, in *Sea Language*, is a ſort of ornamental painting on the upper part of a ſhip's quarter, ſtern, or bow. It generally conſiſts of armour, inſtruments of war, marine emblems, &c.

FREGAROLA, in *Ichthyology*, a name given by many to a ſmall river-fiſh, well known in England by the name of the minow.

FREGATA, in *Ornithology*, a ſpecies of *procellaria*, which ſee.

FREGATA, or *Frigata*, a name given to the PELECANUS *aquilus*, which ſee.

FREGELLANUM, or FREGELLA, in *Ancient Geography*, a town of Italy, in Latium, S.E. of Anagnia, on the Latin way. D'Anville places it to the right of the Liris; but the abbé Chauppy thinks the ſituation was that of Opio, a corruption, as he conceives, of the name Opimius, a Roman conſul, who deſtroyed Fregella; Fregellanum having been built on its ruins.

FREGENA, a town and colony of Italy, in Etruria, ſituated on the ſea-coaſt.

FREGGIA, in *Ichthyology*, the name of a long anguilliform fiſh of the tænia kind, more commonly called *cavagiro*. It is the CEPOLA *tænia*.

FREGIT CLAUSUM. See CLAUSUM.

FREHEL, CAPE, in *Geography*, a cape on the W. coaſt of France; 12 miles W. of St. Malo. N. lat. 48° 38'. W. long. 2° 13'.

FREHER, MARQUARD, in *Biography*, an eminent juriſt and man of letters, was born at Augſburg in the year 1565. He was educated for the profeſſion of the law, firſt at Altdorff and then at Bourges. His firſt office was that of counſellor to the elector-palatine, John Caſimir, and in 1596 he obtained the profeſſorſhip of the law in the univerſity of Heidelberg. By the elector Frederic IV. he was employed in various important concerns, and created vice-preſident of the ſenate. He was a very diſtinguiſhed negociator, but did not, by engaging in diplomatic concerns, neglect his literary purſuits, which were particularly directed to hiſtory and antiquities. He was author of many learned works: of theſe the principal is, "De re monetaria veterum Romanorum, et hodierni apud Germanos Imperii Liber." He was a collector of ancient paintings, and poſſeſſed a well choſen cabinet of medals, many of which he elucidated in his writings. He died at Heidelberg in the year 1614. Moreri.

FREIBURG, in *Geography*, a town of the duchy of Bremen; 16 miles N. of Stade.

FREIDDEG, a town of Auſtria; 7 miles S.S.W. of Ips.

FREIDNAU, a town of the duchy of Stiria; 6 miles W. of Rakelſpurg.

FREJENAL, or FREXENEL, a town of Spain, in the country of Seville; 47 miles N. of Seville.

FREIENHAGEN, a town of Germany, in the principality of Waldeck, on the Watter; 18 miles W. of Caſſel. —Alſo, a town of Brandenburg, in the Mark of Prignitz; 69 miles N.W. of Berlin. N. lat. 53° 17'. E. long. 12° 27'.

FREIENSTEIN, a town of Germany, in the county of Erbach; 10 miles S. of Erbach.

FREIENWELDE, a town of Germany, in the duchy of Pomerania; 15 miles N.E. of Stargard. N. lat. 53° 36'. E. long. 15° 23'.

FREIGHT. See FRAIGHT.

FREIMERSHEIM, in *Geography*, a town of France, in the department of Mont Tonnerre, taken by the French in 1794; 4 miles N.N.E. of Landau, and 12 S.W. of Spire.

FREIN, or WRANOW, a town of Moravia, in the circle of Znaym; 8 miles W. of Znaym.

FREIND, JOHN, in *Biography*, a celebrated phyſician, was born in 1675, at Croton, in Northamptonſhire, of which place his father was rector. He was educated at Weſtminſter ſchool, under Dr. Buſby, and was thence elected, in 1690, into Chriſt-church college, Oxford. Here he was conſiderably diſtinguiſhed by his claſſical attainments, to which Dr. Aldrich gave teſtimony, by ſelecting him, together with Mr. Foulkes, for the taſk of publiſhing a Latin tranſlation of the oration of Æſchines againſt Cteſiphon, and of Demoſthenes de Corona. Having for ſome time purſued the ſtudy of phyſic, he communicated to the Royal Society, in 1699, an account of a remarkable hydrocephalus, and in 1701 a relation of a ſingular convulſive diſeaſe affecting two poor families in Oxfordſhire. In 1703 he publiſhed a work, which immediately brought him into notice as a phyſiologiſt and phyſician, entitled, "Emmenologia, in qua fluxus muliebris menſtrui phænomena, periodi, vitia, cum medendi methodo, ad rationes mechanicas exiguntur," Oxford, in 4to. In this work, which was favourably received, and went through ſeveral editions, in tranſlations, on the continent, Freind adopted the principles of the mechanical ſect of phyſicians, which then flouriſhed under the auſpices of Baglivi, and other learned men. He conſidered local plethora as the cauſe of the evacuation, and attributed its diminution or deficiency to a lentor of the blood, and a rigidity of the veſſels, and its exceſs to the oppoſite condition of tenuity of the blood, and laxity of the veſſels; whence his plan of cure was derived. In the year 1704 he was appointed profeſſor of chemiſtry at Oxford; and in his lectures he attempted, after the example of Keil, to explain the operations of this art, alſo upon mechanical principles. In the enſuing year, however, he accompanied the earl of Peterborough, in his expedition to Spain, in the quality of phyſician to the Engliſh forces. He was abroad two years, and returned through Italy, viſiting Baglivi and Lanciſi at Rome, by whom he was received with diſtinction, his reputation having already reached that capital. On his return, in 1707, he was created doctor by diploma, and publiſhed his chemical lectures in Latin, under the title of "Prælectiones Chymicæ in quibus omnes fere Operationes Chymicæ ad vera principia et ipſius naturæ leges rediguntur." Theſe lectures were nine in number, and were dedicated to ſir Iſaac Newton. He was elected a fellow of the Royal Society in 1712; but in the ſame year quitted London in order to accompany the

troops

troops under the command of the duke of Ormond, into Flanders. On the concluſion of peace in the following year he returned to London, where he chiefly reſided afterwards, and roſe to high profeſſional reputation. In 1716 he was received as fellow of the College of Phyſicians, and in that year publiſhed the firſt and third books of Hippocrates on epidemics, with the addition of a commentary on fevers, in nine parts, under the title of "Hippocratis de morbis popularibus liber primus et tertius: his accommodavit novem de Febribus Commentarios I. Freind M. D." This is a performance of great erudition, affording a perſpicuous view of the practice of the Greek phyſicians, of which he was for the moſt part a zealous defender. He was attacked with unbecoming acrimony, on account of ſome obſervations made in theſe commentaries, relative to the advantages of purgative medicines in the ſecondary fever of confluent ſmall pox, by Dr. Woodward, in a treatiſe entitled "The State of Phyſic and Diſeaſes." To this Dr. Freind firſt oppoſed a ludicrous reply, in the name of a noted empiric, one Byfield. At length he thought proper to anſwer it ſeriouſly, in a letter addreſſed in Latin to Dr. Mead, with the title of "De Purgantibus in ſecundo Variolarum Confluentium febre adhibendis," 1719, 8vo.—This letter contains many valuable obſervations, deduced both from theory and practice, elegantly expreſſed, which contributed to eſtabliſh the practice for which he contended. He paſſed through the offices of the college, and in 1720 delivered an Harveian oration, which was much applauded.

Hitherto Dr. Freind had confined himſelf to medical and philoſophical purſuits with great reputation and ſucceſs; but in 1722, for what reaſons we know not, he was induced to engage in political life, and entered into parliament as burgeſs for Launceſton. His connections were with the party at this time in oppoſition to the court; and as the times were critical, and his attachments warm, his conduct ſoon expoſed him to ſuſpicion. Biſhop Atterbury's plot for the reſtoration of the Stuart family was the leading topic of this period; and when a motion was made againſt the prelate in the houſe of commons, Dr. Freind was among the ſpeakers in his favour. As the circumſtances of the time had given the miniſtry a pretext for the ſuſpenſion of the habeas corpus act, ſeveral perſons of conſequence were committed to priſon, among whom was our phyſician, charged with ſuſpicion of high treaſon. The oppoſition ſuggeſted that the only ground for this was his parliamentary conduct; but Walpole declared privately to ſeveral perſons, that there was poſitive proof of the blackeſt treaſon againſt him. This, however, (as in many inſtances of a ſimilar kind,) was never brought forward; and, after a confinement in the Tower from March 15, 1723, to June 21ſt, of the ſame year, he was admitted to bail, his ſureties being Dr. Mead, and three others of his brethren. He appeared at the king's bench in November following, and was finally diſcharged. For the honour of Dr. Mead, however, the mode in which his liberation was procured muſt not be omitted to be noticed. Being called to attend ſir R. Walpole in ſickneſs, that phyſician refuſed to undertake the cure of the miniſter until Dr. Freind was ſet at liberty. He afterwards made over to Dr. Freind 5000 guineas which he had received in fees from his (Dr. F.'s) patients. His mind was tranquil enough on this occaſion to ſuffer him to employ his leiſure in the Tower in drawing up a ſecond Latin epiſtle to Dr. Mead, concerning the ſmall-pox, entitled, "De quibuſdam Variolarum generibus Epiſtola," 1723. During his confinement he alſo formed the plan of his great work, of which the firſt part appeared in 1725, and the ſecond in 1726. This was entitled "The Hiſtory of Phyſic from the Time of Galen to the beginning of the Sixteenth Century, chiefly with regard to Practice; in a Diſcourſe written to Dr. Mead," in two volumes 8vo. This work was ſuggeſted by the Hiſtoire de la Medecine of Daniel Le Clerc, which terminated with Galen, and to which Dr. Freind intended it as a kind of ſupplement. It is divided into three parts, in which the Greek phyſicians, the Arabians, and the moderns are reſpectively treated of. The author did not attempt a biography of the leading phyſicians, nor a minute analyſis of their works, but only notes the peculiarities of each in point of theory and practice, occaſionally interſperſing his own obſervations. This work was much read, both at home and abroad, in tranſlations, and continues to be a ſtandard work. It was attacked, however, from ſeveral quarters. Sir Clifton Winteringham publiſhed, anonymouſly, a tract, entitled, "Obſervations on Dr. Freind's Hiſtory of Phyſic, ſhewing ſome falſe repreſentations of Ancient and Modern Phyſicians, by C. W. D. M." 1726. And the celebrated John Le Clerc made ſome animadverſions upon it, in defence of his brother Daniel, in the "Bibliotheque Ancienne et Moderne," tome XXVI., chiefly in regard to ſome points of chronology. The controverſy was maintained by the interference of ſeveral writers on both ſides. The errors of Le Clerc, pointed out by Freind, are, however, acknowledged, as well as ſome miſtakes of his cenſurer.

Whatever political ſuſpicions might have fallen upon Dr. Freind in conſequence of his connections, the ſtain of diſaffection to the reigning family muſt be regarded as obliterated, by his appointment, on the acceſſion of George II., to the office of phyſician to queen Caroline. He did not long, however, enjoy this honourable truſt, for he died in July, 1728, in the fifty-ſecond year of his age, much regretted by all; and the care which his ſovereign afterwards extended to his widow and his ſon, evinced the eſteem in which he had been held by that prince.

The Latin works of Dr. Freind were publiſhed by Dr. Wigan in a folio volume, London, 1733, together with a Latin verſion of the Hiſtory of Phyſic, and a life of the author by that editor. Several foreign editions of the ſame collection have alſo been publiſhed. Eloy. Dict. Hiſt. Gen. Biog. Sprengel, Geſchichte der Artzn.

FREINDORF, in *Geography*, a town of Auſtria, four miles S.E. of Tulla.

FREINSHEIM, John, in *Biography*, was born at Ulm in 1608. He ſtudied at various German univerſities, and was patronized by Matthew Berneger. He improved every advantage of which he was poſſeſſed by inceſſant diligence, and carried his reſearches into every part of literature. His knowledge of the languages was very extenſive, and comprehended not only thoſe which are now dead, and which have acquired the title of learned, but likewiſe moſt of thoſe in modern uſe. In 1634 he was invited to Metz to occupy the poſt of interpreter to the king's ſecretaries; here he continued three years, and returned and married the daughter of his patron, with whom he took up his reſidence. In 1642 he was appointed profeſſor of politics and eloquence at Upſal, and after five years queen Chriſtina engaged him, with a liberal ſalary, to act as her librarian and hiſtoriographer. In 1652 he was invited to Heidelberg by the elector Charles Lewis, and created electoral counſellor, and honorary profeſſor of the univerſity. In this ſituation, to which his talents and manners were admirably adapted, he cultivated an extenſive correſpondence with the learned throughout Europe, and was honoured with the friendſhip and eſteem of many perſons of rank. He died in 1660, at the age of fifty-two. As a critic he illuſtrated with learned com-

commentaries, the Latin hiſtorians Florus, Q. Curtius, and Tacitus, and compoſed ſupplements for the loſt books of Livy. He was author of many Latin orations, poems, and diſſertations; and in his youth he wrote German poems, one of which introduced him to the notice of Berneger. Moreri.

FREINSHEIM, in *Geography*, a town of Germany, in the palatinate of the Rhine; 10 miles W.N.W. of Manheim.

FREIRE, DE ANDRADA, HYACINTH, in *Biography*, was born about the year 1597, at Beja in Portugal. He was educated at Coimbra, where he took the degree of doctor in canon law, and applied to the ſtudy of theology. He likewiſe engaged in a political queſtion of conſiderable intereſt at that time, and wrote a treatiſe, entitled "Portugal Reſtaurado," in which he zealouſly maintained the right of the houſe of Braganza to the crown. When he had taken prieſt's orders, he went to the court of Spain, and was patronized by the firſt miniſter of Philip IV. who conferred upon him a valuable abbacy in the province of Beira. The freedom with which he vindicated the rights of his country deſtroyed, in a ſhort time, all his proſpects of future advancement, and even brought him into ſome perſonal danger. He declared to his patron, without reſerve, when the queſtion was put to him, that the rights of the king of Spain to the crown of Portugal were thoſe only of force and uſurpation, and having compoſed a work in favour of the title of Catherine the ducheſs of Braganza, an order was iſſued for his arreſt, but he fortunately eſcaped to his abbey, and there continued a voluntary priſoner till the acceſſion of John IV. to the crown of Portugal in 1640, by whom he was received with the diſtinction and reſpect that his patriotiſm merited. He was offered the appointment of preceptor to the prince, which he declined, as he did the nomination to a biſhopric, foreſeeing that the pope would probably refuſe to confirm the election, ſaying that "he did not chooſe to be a biſhop as players were kings and emperors." Diſſatisfied with the manners and principles of the court, he retired in a few years to his abbey, with which he was equally diſguſted, and on the death of his father he returned to Liſbon to ſettle his family affairs, and continued there till his death in 1657. He was a frank, generous and upright character, liberal to the needy, and warmly attached to his friends, whom he defended and juſtified in their abſence, but whoſe faults he did not ſpare when they were together. He was an elegant author, publiſhed ſome poems, which may be found in a collection printed at Liſbon under the title of "Fenix Renacida;" but his moſt important work is "The life of Don John de Caſtro," which is eſteemed one of the beſt compoſed books in the Portugueſe language. Moreri.

FREISACH, in *Geography*, a town of Germany, in the duchy of Carinthia, belonging to the archbiſhopric of Salzburg, ſituated on the Metnitz; having a caſtle, college, convent of Dominicans, and commandery of the Teutonic order; taken by the French in 1797; eight miles N. of St. Veit.

FREISCHBACH, a town of France, in the department of Mont Tonnerre, lately belonging to the palatinate of the Rhine; taken by the French in 1794; ſix miles E.N.E. of Landau.

FREISHEIN, a town of Moravia, in the circle of Znaym; 20 miles W.N.W. of Znaym.

FREITAG, JOHN, in *Biography*, a phyſician, was born at Nieder Weſel, in the duchy of Cleves, on the 30th of October 1581. His relations were compelled, by the troubles of the times, to retire to Oſnaburg, and there young Freitag began his claſſical ſtudies. He was afterwards ſent to Cologne, but was ſoon recalled by his parents from the fear that he might acquire principles, in that univerſity, contrary to thoſe of the proteſtant religion which they profeſſed. After completing his claſſical purſuits at Weſel, he commenced the ſtudy of philoſophy at Helmſtadt; but his diſpoſition being early turned to medicine, as a profeſſion, he ſtudied at Roſtock, afterwards returned to Helmſtadt to attend the lectures of Duncan Liddell and of Francis Parcovius; he likewiſe derived much advantage from the lectures of the celebrated Meibomius, in whoſe houſe he reſided in the capacity of tutor to his ſon, and therefore had frequent opportunities of converſing on the ſubject of medicine with that able maſter. The progreſs of his improvement in this ſcience was ſo great, that permiſſion was given to him of giving private lectures to the younger ſtudents on the practice. He afterwards lectured in public as profeſſor extraordinary; and in 1604, that is, at the age of 23 years, he obtained the ordinary profeſſorſhip in the univerſity, which office he filled during four years. At the end of this time he obtained his degree of doctor, and went to the court of Philip Sigiſmund, duke of Brunſwick Lunenburg, and biſhop of Oſnaburg, who had appointed him his principal phyſician. About the year 1622, Erneſt, duke of Holſtein and earl of Schawenburg, offered him the ſame office, with the addition of the chief medical profeſſorſhip in the univerſity which he had lately founded at Rinteln; but his patron would not permit him to accept it. This prince-biſhop dying in 1623, his nephew, duke Frederic Ulric, gave Freitag the option of being his chief phyſician, or of reſuming his profeſſorſhip at Helmſtadt. He continued at Oſnaburg, where the new biſhop retained him as his phyſician, and alſo appointed him one of his chamberlains. He alſo ſerved his ſucceſſor in the ſame capacity, but was diſmiſſed in 1631, on account of his refuſal to become a catholic. He found protection and patronage, however, under Erneſt Caſſimir, count of Naſſau, and the counts of Bertheim, who procured for him the vacant profeſſorſhip in the univerſity of Groningen. He fulfilled this new appointment with great reputation, and continued to diſtinguiſh himſelf by the ſucceſs of his practice till the decline of his life, which was accelerated by a complication of maladies. Dropſy, gout, gravel, and fever terminated his exiſtence on the 8th of February, 1641, in the 60th year of his age.

Freitag was a follower of the chemical ſect, and alſo a partiſan of the philoſophy of the ancients, to which indeed he retained his attachment with ſo much bigotry, that no efforts of his friends could ever prevail upon him to change his opinion. He publiſhed ſeveral works. 1. "Noctes Medicæ, ſive de Abuſu Medicinæ Tractatus," Francfort, 1616.—2. "Aurora Medicorum Galeno-chemicorum, ſeu de rectâ purgandi methodo è priſcis ſapientiæ decretis poſtliminio in lucem redacta," Ibid. 1630.—3. "Diſputatio Medica de morbis ſubſtantiæ et cognatis quæſtionibus, contra hujus temporis Novatores et Paradoxologos," Groningen, 1632.—4. "Diſputatio Medica calidi innati eſſentiam juxta veteris Medicinæ & Philoſophiæ decreta explicans, oppoſita Neotericorum et Novatorum Paradoxis," Ibid. 1632.—5. "De Oſſis natura et medicamentis opiatis Liber ſingularis, &c." Groningen 1632.—6. "Diſputatio Medico-philoſophica de Formarum origine," Groningen, 1663.—7. "Oratio panegyrica de perſona et officio Pharmacopæi," &c. Ibid, 1633.—8. "Detectio et ſolida Refutatio novæ Sectæ Sennerto-Paracelſicæ," Amſterdam, 1636.

FREJUS, in *Geography*, a town of France, in the department of the Var, and chief place of a canton in the diſtrict of Draguignan. The place contains 2229, and the canton 7797 inhabitants, in a territory of 497½ kiliometres, in 6 communes. This was formerly a conſiderable place, called

"Forum

"Forum Julii," and the birth-place of Agricola, but it is now a ſmall fortified town, containing a cathedral, a pariſh church, and 4 convents. Its ſituation is marſhy and inſalubrious to the left of the Argens, about half a league from the ſea-coaſt, 16 leagues N.E. of Toulon, and 12 N.W. of Nice. Its port is choaked up. Among the remains of antiquity are a Roman amphitheatre and an aqueduct. N. lat. 43° 25′ 52″. E. long. 6° 45′ 54″.

FREIXEL, a town of Portugal, in the province of Tra los Montes; 15 miles S. of Mirandela.

FREIXIERA, a town of Portugal, in the province of Entre Duero e Minho; ſeven miles N.E. of Amarante.

FREMONA, a town of Abyſſinia, in the kingdom of Tígré, where the Portugueſe miſſionaries took up their firſt reſidence; 50 miles N.E. of Siré. N. lat. 14° 40′. E. long. 38° 18′.

FREMONT, D'ABLANCOURT, NICHOLAS DE, in *Biography*, flouriſhed towards the cloſe of the 17th century. He was nephew of Perrot d'Ablancourt, who undertook the charge of his education, to which the young man did much credit by an early diſplay of his knowledge and great talents. In 1663 he was appointed envoy from France to the court of Portugal, and in 1675 reſident at Straſburg. After this he returned to France, and ſpent his time in ſtudy and in the ſociety of the learned. At the revocation of the edict of Nantes he was obliged to quit his country on account of his ſteady attachment to the Proteſtant cauſe. From the prince and princeſs of Orange he obtained a penſion as hiſtoriographer. He died in 1693. As an author he added to his uncle's tranſlation of Lucian, the dialogue between the letters of the alphabet, and the ſupplement to the true hiſtory. He publiſhed ſome elegant dialogues, and a French catechiſm. After his death appeared his "Memoirs concerning the hiſtory of Portugal, from the treaty of the Pyrenees to 1668." Moreri. Bayle.

FREMUR, in *Geography*, a river of France, which runs into the Engliſh channel. N. lat. 48° 35′. W. long. 2° 12′.

FRENCH, FRANÇOIS, abſolutely uſed, ſignifies the language of the people of France.

The French, as it now ſtands, is no original, or mother-language, but a medley of ſeveral: there is ſcarcely any language from which it has not borrowed words, or perhaps phraſes.

The languages that prevail moſt, and that are, as it were, the baſes thereof, are, 1. The Celtic; whether that were a particular language itſelf, or whether it were only a dialect of the Gothic, as ſpoke in the Weſt and North. 2. The Latin, which the Romans carried with them into the Gauls, when they made the conqueſt thereof. And, 3. The Teutonic, or that dialect of the Teutonic ſpoken by the Franks, when they paſſed the Rhine and eſtabliſhed themſelves in Gaul.

Of theſe three languages, in the ſpace of about thirteen hundred years, was the preſent French formed, ſuch as it is now found. Its progreſs was very ſlow; and both the Italian and Spaniſh were regular languages long before the French.

Paſquier obſerves, it was under Philip de Valois that the French tongue firſt began to be poliſhed; and that, in the regiſter of the chamber of accounts of that time, there is a purity perceived almoſt equal to that of the preſent age.

However, the French was ſtill a very imperfect language till the reign of Franies I. The cuſtom of ſpeaking Latin at the bar, and of writing the public acts and inſtruments of the courts of juſtice in that language, had made them overlook the French, their own language. Beſides, the preceding ages had been remarkable for their ignorance, which was owing, in good meaſure, to the long and calamitous wars in which France had been engaged; whence the French nobleſſe deemed it a kind of merit not to know any thing; and the generals regarded little, whether or not they wrote and talked politely, provided they could but fight well.

But Francis I. who was the reſtorer of learning, and the father of the learned, changed the face of things; and, after his time, Henry Stephens printed his book, "De la Precellence du Langage François."

The change was become very conſpicuous at the end of the ſixteenth century; and under Henry IV. Amyot, Coeffeteau, and Malherbe, contributed towards bringing it to its perfection; which the cardinal de Richelieu completed, by the eſtabliſhment of the French academy; an aſſembly, wherein the moſt diſtinguiſhed perſons of the church, the ſword, and the gown, have been members.

Nor did the long reign of Louis XIV. contribute a little to the improvement of the language: the perſonal qualities of that prince, and his taſte for the polite arts, and that of the princes of the blood, rendered his court the politeſt in Europe. Wit and magnificence ſeemed to vie; and his generals might have diſputed with the Greeks, Romans, &c. the glory of writing well, if they could not that of fighting.

From court, the elegance and purity of the language ſoon ſpread itſelf into the provinces; and now there is ſcarcely any body there who does not write and ſpeak good French. One of the characters of the French language is, to be natural and eaſy. The words are ranged in it much in the ſame order as the ideas in our minds; in which it differs exceedingly from the Greek and Latin, where the inverſion of the natural order of words is reputed a beauty. Indeed the Hebrew ſurpaſſes even the French in this point; but then it comes ſhort of it in copiouſneſs and variety.

It muſt be added, however, that as to the analogy of grammar, and the ſimplicity with which the moods of verbs are formed, the Engliſh has the advantage, not only over the French, but over all the known languages in the world; but then the turns, the expreſſions, and the idioms, of the Engliſh, are ſometimes ſo quaint and extraordinary, that it loſes a good deal of the advantage which its grammatical ſimplicity gives it over the reſt.

The French has but few compound words: wherein it differs widely from the Greek, High Dutch, and Engliſh. This the French authors own a great diſadvantage in their language; the Greek and Dutch deriving a great part of their force and energy from the compoſition of words, and frequently expreſſing that in one ſounding word, which the French cannot expreſs but by a periphraſis. The diminutives in the French are as few as the compounds; the greateſt part of thoſe remaining in uſe having loſt their diminutive ſignification; but what diſtinguiſh the French moſt are its juſtneſs, purity, accuracy, and flexibility.

French is the moſt univerſal and extenſive language in Europe. The policy of ſtates and courts has rendered it neceſſary for the miniſters of princes, and their officers, &c. and the taſte of arts and ſciences has had the ſame effect with regard to the learned.

In Germany, and elſewhere, the princes and perſons of diſtinction value themſelves on underſtanding French; and in ſeveral courts of Europe, French is almoſt as much known as the language of the country; though the court of Vienna

is an exception from this rule. French is there very little uſed; the emperor Leopold could not bear to hear it ſpoken in his court; the Latin and Italian are there cultivated inſtead of it. This extenſiveneſs of the French language is no modern advantage; William the Conqueror gave laws to England in the French language; and the ancient cuſtoms of moſt of the provinces of the Netherlands are written in the ſame.

Laſtly, the French is the ſame language every where; not only in all the provinces of France, but in all places where it is ſpoken, out of France.

For a critical acquaintance with what regards the French tongue, ſee the Remarques of M. Vaugelas; and the obſervations M. Corneille has made on thoſe remarks; the Remarques of F. Bouhours; and the doubts of a Basbreton gentleman, by the ſame father; the converſations of Ariſte and Eugene; the obſervations of M. Menage, and his etymologies, with thoſe of M. Huet; F. Buffier's French grammar; and that of the abbé Regnier. Add, the two diſcourſes of the abbé de Dangeau; one on the vowels, and the other on the conſonants, and many later works.

French, in *Geography*, a conſiderable river of America, in the Maſſachuſetts, which iſſues from a ſmall pond on the borders of Leiceſter and Spencer, in Worceſter county, and which runs through Oxford, and joins Quinebauge river, in Thompſon townſhip, in Connecticut. It derives its name from the French proteſtants who obtained a ſettlement in the town of Oxford, after the revocation of the edict of Nantes in 1685.

French *Bay*, a bay in the ſtraits of Magellan, on the coaſt of Patagonia. S. lat. 53° 51'. W. long. 72° 24'.

French *Barley*, in *Agriculture*, a name given to a ſort of barley which has the grain naked like wheat, but the ear ſhaped in a ſimilar manner to that of common barley. It is a kind of barley which is ſaid to afford a large increaſe, and to make good malt and bread. It is ſometimes denominated *wheat-barley*.

French *Bean*, a ſort of bean moſtly grown in the garden; but which may be cultivated in the field where the ſoil is light and mellow, with great advantage. See Kidney-bean and Phaseolus.

French *Bole*. See Bole.

French *Bread*. See Bread.

French *Broad*, in *Geography*, a navigable river of America, in the Teneſſee, which riſes on the S. E. ſide of the great Iron and Bald mountains in North Carolina. It is formed by two principal branches, which receive ſeveral ſtreams in their courſe, and unite about 58 miles from the ſource of the Nolachucky, the eaſtern branch; thence it flows northerly about 25 miles, and joins the Holſton, 11 miles above Knoxville, and is four or 500 yards wide. The navigation of this branch is much impeded by rocks, and ſo likewiſe is the Teneſſee branch, which joins the main river 50 miles below this. A large, clear, medicinal ſpring, ſaid to be efficacious in the cure of many diſeaſes, has been lately diſcovered on the waters of this river, about 30 miles in a direct line from its mouth. The water is ſo hot that a perſon, upon firſt going into it, can ſcarcely endure it. Nearer the mouth of the river, a valuable lead mine has been diſcovered.

French *Character*, *Coins*, *Companies*. See the ſubſtantives.

French *Creek*, in *Geography*, a north-weſtern water of Alleghany river, into which it falls along the N. ſide of Fort Franklin, 80 miles N. by E. of Pittſburgh. This affords the neareſt paſſage to lake Erie. It is navigable with ſmall boats to Le Bœuf, by a very crooked channel; the portage thence to Preſque iſle, from an adjoining peninſula, is 15 miles. This is the uſual route from Quebec to Ohio.—Alſo, a river of Kentucky, which runs into the Ohio. N. lat. 37° 47'. W. long. 86° 40'.

French *Graſs*, in *Agriculture*, a name given by our farmers to a plant raiſed for the food of cattle, and more properly called ſaint-foin. It had its name French graſs, from its coming originally to us from France, and from its uſe in ſerving, both freſh and dried, for the food of cattle; the common clover is called graſs alſo by the farmers, though neither this nor the other are properly graſſes. Some of our farmers alſo call it everlaſting graſs, from its long continuance, a ſtrong crop often yielding a plentiful annual produce for forty years without any renewing.

French *Key*, in *Geography*, a ſmall iſland in the Spaniſh Main, near the Moſquito ſhore. N. lat. 11° 12'. W. long. 82° 50'.

French *Keys*, two ſmall iſlands among the Bahamas, S. of Mayaguana. N. lat. 22° 35'. W. long. 73° 36.

French *Meaſures*, *Money*. See the ſubſtantives.

French *Muſic*, muſic in the national ſtyle of France. The whole French nation ſeems at preſent pretty generally to have relinquiſhed their old ſtyle of muſic, for cenſuring which, fifty years ago, Rouſſeau was burnt in effigy at the door of the opera houſe at Paris. Lulli is given up; la baſſe fondamentale, and the operas of Rameau, which were thought to do ſo much honour to the nation, are fading faſt, yet they have ſtill a few adherents. But the muſical critics in France, particularly the Gluckiſts, ſo deciſively ſet up their muſic againſt every other, that they ſeem to expect all Europe not only to bow down to them, but to aſk pardon for ever having been pleaſed with any other ſpecies of muſic than that produced on the model of the operas of Gluck! Theſe gentlemen neither ſee nor hear any thing but defects in the fineſt compoſitions of Italy. The abbé Rouſſier is "un enragé" for "la troiſieme progreſſion," and M. Laborde, for that and the compoſitions of Rameau; while the abbé Feytou falls foul on whatever has been ſaid or done in the theory of muſic, except by himſelf; of the practice, or the merits of compoſition or performance, neither he nor the abbé Rouſſier ſeem to care one farthing. It is eaſy to diſcover in ſome articles of the Encycl. Methodique, and other writings, that there are ſome lovers of muſic in France, who really feel the elegance, grace, and expreſſion of Italian vocal muſic; and who are truly ſenſible of the defects and deficiencies of French ſinging. All nations are ambitious of having operas in their native language. The French, the Germans, the Engliſh, the Poles, and the Ruſſians have their national theatres; but all the courts in Europe have had ſerious operas in the Italian language, compoſed and performed by Italians, except the French. The French, the Engliſh, and the Germans, are very wiſe in aboliſhing recitative from their muſical dramas. No country, except Italy, has a genuine recitative; but muſt the Italians, who have one diſtinct from declamation and ſong, muſt they renounce the original characteriſtic of an opera to oblige, or rather to appeaſe their neighbours? The French certainly manifeſt good ſenſe and good taſte in excluding long airs either of bravura or cantabile, till ſingers can be found to execute them: but in countries like Italy, where good ſingers abound, and in other countries where Italian ſingers are tolerated and ſupported, are they to prohibit good ſinging in their theatres to humour French critics? See Opera and Recitative.

French ſinging at the ſerious opera of "Iphigenie en Tauride," has been very aptly compared, not to a female

in

in diſtreſs, but in labour during the throes of childbirth. The French, always partial to "la muſique criarde," have had their taſte flattered by Gluck, who knew that though they could not ſing, they could *ſcream* to ſome tune. His harſh modulations, and their "éclats de voix," augmented, "à force de l'Orcheſtre," he was ſure would be *well heard*, and fix his fame.

FRENCH *Nuts*, a term ſometimes provincially employed to ſignify bruſh-wood; and alſo wall-nuts.

FRENCH *Order*, *Padſaddle*. See the ſubſtantives.

FRENCH *Park*, in *Geography*, a ſmall poſt town or rather village in the county of Roſcommon, Ireland; 83 miles W. by N. from Dublin, and about eight miles from Tulſk.

FRENCH *Pox*. See Pox.

FRENCH *River*, in *Geography*, a river of Upper Canada, of irregular breadth and form, and crowded with iſlands, ſo that its real banks are ſeldom ſeen. It enters lake Huron from the N. E. in N. lat. 45° 53'.

FRENCH *School of Engraving*. The art of engraving, ſo as to deliver impreſſions on paper, was introduced into France from the neighbouring empire of Germany ſome time about the middle of the fifteenth century. The preciſe year of its introduction has not been recorded. The benefits it has ſince conferred, and is ſtill conferring on Europe, are on all hands acknowledged to be great, yet the art appears to have entered France, with all the unobſerved humility of an apoſtle of our holy religion; and that highly cultivated country, to which cultivation the art of engraving has contributed in no trifling degree, to be indebted for its *introduction*, not to the providence of the government, though the government hath ſince done much to accelerate its progreſs, but to the enterprize or neceſſity of ſome individual artiſt, whoſe name has not deſcended to us.

Engraving on wood, or that art which enabled the printer to deliver his work from the ſurface of the engraving, preceded the art of engraving on copper a few years: and both were at firſt employed in France, as in Germany and Italy, in the embelliſhment of books, in which it has been preſumed by Huber and Papillon, that the city of Paris took the lead, though Lyons is ſoon after mentioned.

The moſt ancient French book ornamented with letter-preſs engravings appeared in the year 1482, or ſoon after. It is a tranſlation of "Belial," in one ſmall folio volume, and is ſuppoſed by the French writers to have been printed at Paris, though the name of that city is not mentioned. Yet this book concludes in the following manner, "from which it is not clear whether the tranſlator or printer finiſhed his taſk at the time mentioned."

Here ends the book called "Conſolation for poor Sinners," lately tranſlated into French by the venerable and diſcreet brother Peter Ferget, doctor of theology, and of the order of the Auguſtines. In the year of Grace 1482, and on the 21ſt day of January, he finiſhed this book.

The moſt ancient prints from engravings on copper were alſo the embelliſhments of typographical works. The firſt French book ornamented with copper plates was printed at Lyons in 1488, in folio. This book, the author, or rather tranſlator of which was Nicholas le Huen, a monk of mount Carmel, and profeſſor of theology, is for the moſt part a compilation from the Itinerary of Bernard de Breydenbach, and the title is "A Peregrination beyond Sea in the Holy Land." It concludes with the following words, "Of the peregrinations in Jeruſalem, the environs, and places adjacent. Of mount Sinai, and the glorious Catharine. This work contains the whole deſcription, as far as God would permit it to be known, printed at Lyons by men of ability. Michael Topie of Pyrmont, and James Heremberg of Germany, living at the ſaid Lyon. In the year of our Lord 1488, and on the 28th of November."

In the French work are the views of the ſame cities that are found in the Latin and German editions of the Itinerary of Breydenbach, publiſhed at Mayence in 1486, by Erhard Rewich, with this difference, that the engravings are printed from copper plates in the tranſlation, and with the letter-preſs, and preſumptively from blocks of wood, in the original work. It is not known whether the engraver of theſe plates, (which are of very rude execution,) was a Frenchman or a German. Huber ſpeaks of it as very poſſible that James Herenberg, one of the printers, may have been alſo the engraver of the embelliſhments.

As theſe early works are publiſhed without any engravers' names, (notwithſtanding that in the latter thoſe of the printers are mentioned,) it may ſafely be inferred that thoſe who performed them were little thought of at the time, and that no idea was entertained in France of the future ſuſceptibilities or importance of that art of which theſe were the earlieſt productions. Other anonymous engravings, which have ſince fallen into neglect, were produced before the cloſe of the fifteenth century; but the earlieſt French prints to which the names or monograms of the artiſts appear, are thoſe of Wendel Reich, a foreigner, and preſumptively a German, who was reſident at Lyons in the year 1515, and Jean Duvet, ſometimes called Davet, who was born at Langres in 1510.

Reich engraved on wood, and, according to profeſſor Chriſt, publiſhed many of his works at Lyons, marking them with the cypher which will be found in our plate of the monograms, &c. of the French School of engravers; and, according to the ſame writer, Duvet was known by the name of the Maſter of the Unicorn, from his engravings of the triumphs of that animal. He worked at Paris during the reign of Henry the Second, and publiſhed there ſeveral plates from very Gothic deſigns, and which are engraved in a wretched ſtyle. The principal of them are "Le Dieu Mars," inſcribed I. D. 1530. "Adam and Eve," with the eternal father clothed in a ſacerdotal habit, folio ſize, inſcribed Johannes Duvet fecit. "Moïſe, avec les Patriarchs," folio, and a ſet of twenty-four plates, alſo in folio, of which the ſubjects are taken from the Apocalypſe. Duvet ſometimes placed his initials on a tablet, as appears in our plate of the marks and monograms of French engravers.

Solomon Bernard, frequently termed "le petite Bernard," from the ſmallneſs of his works, appeared ſoon after. He was born in the year 1512; and engraved chiefly for the bookſellers of Lyons, of which city he was a native; though between the years 1550 and 1580, he was alſo employed by thoſe of Tournay and Rouville. The French writers on art ſay, that he became the diſciple of Jean Couſſin; however this may have been, his engravings, which are both on copper and on wood, are executed (conſidering the early period at which they were done) in a clear, neat ſtyle, and diſplay in the deſigns conſiderable ſpirit and fertility of invention.

We have thought proper to give more copious liſts of the works of the engravers of the foreign ſchools than of thoſe of the Engliſh, becauſe ſuch liſts are not hitherto printed in any Engliſh book that has come to our knowledge.

The firſt edition of Bernard's bible, which Strutt ſpeaks of as being his moſt eſteemed production, was publiſhed at Lyons in 1550. Subſequent editions, containing impreſſions from the ſame engravings, have been publiſhed, but collectors eſteem the firſt as far more valuable; and it is now become

extremely rare. In the year 1553 he produced "Les Médailles pour l'Epitome des Antiquités de Jacques Strada. Mantouan, imprimé à Lyon."

Of the other engravings by this maſter, the firſt of the French ſchool that is worthy to be ſo termed, the following are the principal. "Les Metamorphoſes d'Ovide," imprimé à Lyon en 1557. The prints to "L'ane d'or d'Apulée," imprimé à Lyon en 1558. "The Hiſtorical Vignettes to a French Tranſlation of Virgil's Æneid," imprimé à Lyon 1560. "Un Livre de Thermes au nombre de dix-huit," imprimé à Lyon en 1572. "The Hiſtory of Pſyche in thirty-two figures," 12mo. Twenty-two prints of decorations of theatres, &c. Six ſmall emblematical ſubjects in ovals. Two hunting pieces. "A View of the City of Lyons;" (probably the firſt French landſcape that was ever engraven.) "A triumphal Chariot with Arms." "A Head, with a triple Face ſurrounded by Cherubims;" and the ornaments (in ovals) to a book of hymns, printed alſo at Lyons.

Stephanus de Laulne was born at Orleans in the year 1520, and travelled twice to Straſbourg, probably for improvement in his art. At what time he died is not mentioned, but he was at Straſbourg, for the ſecond time, in 1590, when he muſt have been in the ſeventieth year of his age. He made ſome ſucceſsful copies from the engravings of Mark Antonio, which were now in high and deſerved repute; but the far greater part of his prints are from his own deſigns, and being in general ſmall, he is claſſed by collectors among "the little maſters."

De Laulne was a man of conſiderable inventive powers, but though his compoſitions abound with figures which are not ill deſigned, his drawing is frequently defective, particularly in the long and ſlender proportions of his figures, which meagreneſs he probably imbibed from ſtudying too much the productions of the early German engravers. He worked entirely with the graver, and his chiaro-ſcuro is yet more defective than his drawing.

The abbé Marolles mentions three hundred and eighteen engravings by this maſter, of which the following will probably be found the beſt. He ſometimes placed his initials to his works, and at other times only Stephanus fecit. "David beheading Goliah," "The Maſſacre of the Innocents," "The Martyrdom of St. Felicité," "The Rape of Helena," "Alexander commanding the Books of Homer to be ſhut up in the Cheſt of Darius." The above are all copied from Mark Antonio. "The Serpent of Aaron," painted for the Cordeliers of Sens, after Jean Couſſin. This is in folio, and is probably the largeſt print from the hand of this maſter. "The Rape of Hippodamia," after Roſſo. The following are engraved from his own deſigns. A ſet of thirty ſmall ſubjects from the hiſtory of the Old Teſtament. A ſet of four plates of heathen gods, *viz.* Jupiter, Neptune, Mercury, and Ceres, in circles. A ſet of ſix plates, of ſtatues of gods and goddeſſes. A ſet of eighteen mythological ſubjects, ovals. A ſet of twelve, the months of the year circles. A ſet of the four monarchies, in ovals. A ſet of four from ancient hiſtory, in ovals. A ſet of four rural occupations, in ovals. The three Graces, inſcribed Sic Rome Carites niveo ex Marmore ſculp.

Contemporary with de Laulne, but inferior in merit, was Noel Garnier, to whom has been falſely attributed the credit of introducing the art of engraving on copper into France. The French writers on the fine arts ſay, that he was born ſome time about the year 1520, and that preſumptively, judging from his name; he was by birth a Frenchman. His real merit is ſo trifling that this matters but little. He was by education probably a goldſmith, and from the Gothogerman ſtyle of his engravings, it may reaſonably be conjectured that he learned, what he knew of the art, under ſome German goldſmith and engraver. After ſtating, that "his works are very rude and badly executed," Strutt mentions a ſmall plate of a combat between naked men, of whom there are ſeveral, in which he ſeems to have made a feeble attempt at copying the ſtyle of Sebald Beham. The only other engravings that are known to be from the hand of Noel Garnier, are forty-eight plates repreſenting the arts and trades, and an alphabet of capital letters ornamented with figures and foliage. His ſingular mark will be found in our plate of monograms, &c. of the French ſchool.

Pierre Voeiriot, or Woeiriot, engraved both on copper and on wood, and was alſo a goldſmith. He was born at Bar-le-duc, in Lorraine, in the year 1525, but eſtabliſhed himſelf as a goldſmith and engraver at Lyons. His prints, of which there are as many from wood as from copper, are chiefly after his own deſigns, and are tolerably well executed, conſidering the general ſtate of French art at the time.

There is ſtill extant a curious book adorned with engravings on copper by this artiſt, entitled "Pinax Iconicus Antiquorum ac Variorum in Sepulturis Rituum," to which is prefixed his own portrait, and which was printed at Lyons in the year 1556. He occaſionally uſed two monograms, which are ſomewhat complicated, and intended to ſignify Pierre Woeiriot of Bar-le-duc; and Papillon adds, that he marked his engravings on wood with the ſort of double croſs, which will be found in our plate of the monograms and marks uſed by the ancient engravers, and which is called "la petite Croix de Lorrain."

Strutt places the birth of this artiſt in 1510, but does not cite his authority. His principal engravings are as follow. "The Sacrifice of Abraham," in folio. "Moſes ſaved from the Waters," in folio. "Phalaris ſhut up in the brazen Bull," a ſmall upright. "A Woman with two Children in her Arms caſting herſelf on a funeral Pile." Two ſmall landſcapes, in which are introduced a great number of figures. In one is repreſented a funeral oration, in the other two naked men are fighting on the ſummit of a funeral pile. The three latter probably belong to the book which is mentioned above of ſepulchral rites. "The Battle of Conſtantine with Maxentius," after Raffaelle, in folio. The above are all engraven on copper. The medallion of Jacques Bornonius, dated in 1573, is probably one of the beſt of his engravings on wood: it is very delicately cut, its ornamented frame is ſupported by Mercury and Minerva, and it is inſcribed with Greek, Latin, and French verſes, terminating with the following couplet:

"Qui veiut pour ſon pais combattre á tous alarmes
Doit avoir de Mercure et de Pallas les armes."

Jacques Periſin, otherwiſe Periſim, otherwiſe Perſinus, was born in France ſome time about the year 1530. In concert with J. Tortorel, he deſigned and engraved a ſet of twenty-four large prints repreſenting the war of the Huguenots, and other remarkable events relative to the hiſtory of France between the years 1559 (which was marked by the death of Henry II.) and 1569, when the German troops were diſperſed. Some of theſe are executed on copper, and, according to Strutt, others on wood. He ſays, "thoſe on copper are ſlightly *etched*," which, it is worthy of remark, is the firſt time we met with this word in the hiſtory of French engraving, though etching had now been invented near half a century: "the etchings are in a coarſe, incorrect ſtyle, nor have the impreſſions from wood much to recommend them with regard to the compoſitions, but they

are

are executed with a tolerable degree of attention; and the croſs ſtrokes, or hatchings, are well imitated."

The mark of this artiſt will be found in our plate of thoſe of the French ſchool; but he ſometimes inſcribes his name at length, and ſpells it not always alike. It is profeſſor Chriſt who reads it Perriſin, and perhaps juſtly.

René Boivin was born in the province of Anjou in the year 1530, or thereabout. "His plates, in general, are executed with the graver only, in a manner reſembling that of Cornelius Cort;" but in ſome few inſtances he practiſed the art of etching. His works, though not held in the higheſt eſtimation, are by no means devoid of mechanical merit; for he handled the graver with much facility, but his drawing is very defective, particularly in the extremities of his figures.

Boivin ſometimes ſigned his works with his baptiſmal name only, as Renatus fecit, but more frequently with a cypher compoſed of an R and a B, as ſeen in our plate.

He engraved the portraits of the philoſophers and poets of antiquity in twelve plates 4to.; and ſeverally thoſe of Clement Marot, (dated 1556,) Jean Sebaſtian Pfanſerus, George Vicellus, theologian, and himſelf; dated alſo in 1556.

His principal hiſtorical works are, an emblematical plate repreſenting "The Triumph of Virtue, and the Defeat of Vice," a folio plate. "Suſanna and the Elders," in 4to. The plates for a work entitled "Livre de la Conqueſte de la Toiſon d'or, par le Prince Jaſon de Teſſalie." Theſe were deſigned by Leonard Thiri, and are encloſed in ornamental borders.

"Hagar and Iſhmaël before the Houſe of Abraham," a ſpirited etching of a 4to. ſize. "Four Bandits pillaging a Peaſant's Cart," alſo an etching in 4to. "Françoés premier march ſuel au temple de l'Immortalité, et laiſſe loin derrière lui l'ignorance, la ſtupidité, &c."

Leonard Gaultier, or Galter, as he ſometimes deſignated himſelf, is preſumed by the French writers on art to have been a native of France; but profeſſor Chriſt, though without aſſigning his reaſon, ſuppoſes him to have been born in Germany in the year 1560, or thereabout. He worked entirely with the graver, imitating the ſtyles of Criſpin de Paſs and the Wierixes. But while we are ſurpriſed at the great number, preciſion, and neatneſs of his works, we cannot but lament the ſtiffneſs and incorrectneſs of deſign by which they are equally characterized. According to the abbé Marolles, the number of prints engraved by this maſter amount to eight hundred, and they are chiefly from his own deſigns, though he ſometimes worked after Raffaelle, Rubel, Caron, and Dumouſtier. His engraving of the Laſt Judgment of Michael Angelo was not done from the original picture, but copied from the plate by Martin Rota. His cypher, or monogram, will be found among thoſe of the French ſchool. The liſt of his principal engravings is as follows:

"The Loves of Cupid and Pſyche," after Raffaelle, in 8vo., not engraved from the original pictures, but through the medium of the prints of Auguſtino Veneziano. The "Proceſſion of the League," a ſatyrical piece, in folio. The "Family of Henry IV." folio. The "Aſſaſſination of Henry IV." folio. The "Coronation of Maria de Médicis," folio; inſcribed L. Gaultier, ſc. 1610. The "Cyclopes forging Thunder-bolts," folio.; after Jean Couſen, inſcribed Léonár Galte fecit, 1581. "A Sacrifice," in the antique ſtyle, folio; after Martin Freiment. A ſet from the Old and New Teſtament, in 4to. A ſet of the prophets, apoſtles, and evangeliſts, in 8vo., and the following portraits: Philippe de Mornay, lord of Pleſſis, in folio, 1611. Alexandre Bouchart, viſcount Bloſſeville, folio; after Dumouſtier, 1613. Meſſire Jacques Amyot, biſhop of Auxerre. Henry III., by the grace of God king of France and Poland; inſcribed L. Gaultier fecit. 4to. Stephan. Paſchinus Regiarum Rationum Patronus, 1617. 4to. Petrus Aerodius Quæſitor Andegavus, 1615. 4to. Charles de Gontaut de Biron, mareſchal of France, 4to. Henry, duke of Montpenſier, 4to.

Melchior Tavernier began to reſide at Paris, where he publiſhed his own engravings, ſome time about the year 1620. He was originally of Anvers, and is the firſt whom we find honoured in France with the title of engraver to the king. Yet nominal honours and real merit are not inſeparable. Tavernier's real ſtock of talent as an artiſt was inconſiderable. His productions are chiefly portraits and maps, with ſome few ornaments, and other ſubjects of minor importance, from his own deſigns, and from thoſe of Danier Rabel.

His principal plate is a large upright folio, of which the ſubject is an equeſtrian ſtatue of Henry IV. of France, ſuperſcribed "Melchior Taverneir, à Paris, graveur et imprimeur du Roi, pour le tailles douces, demeurant l'iſle du palais, ſur le quay de l'eſpy d'or, 1627."

Of his ſmaller works, a buſt of the duke d'Aleçon, crowned with laurel, with four French veres, in 8vo. is among the beſt.

Huber has choſen to conſider the boaſt of Melchior Tavernier, that his father Gabriel firſt brought to Paris the art of engraving on metal, as unfounded: but Huber's premiſes do not neceſſarily lead to this concluſion, and the preſent writer will readily pardon the court of France, if, on account of this merit of his anceſtor, Melchior was created engraver to the king; for if the ſins of the fathers may religiouſly be viſited on the children, ſurely their virtues may alſo be viſited.

Melchior ſays, "there was not till that time (the time that Gabriel Tavernier of Anvers introduced the art of engraving on metal,) any one in the kingdom of France who practiſed the art, nor any one who knew its excellence."

Now according to the ſame writer, (Huber,) Melchior was born in the year 1560, or thereabout; it therefore only requires that Gabriel ſhould have practiſed engraving on metal about thirty years before the birth of his ſon, (which is ſurely by no means incredible,) to ſubſtantiate the ſon's ſtatement: yet it muſt be confeſſed that none of Gabriel's engravings have been ſeen by the preſent writer, nor are any mentioned by Melchior or any other of the French writers on art.

The honours which poſterity have awarded to Jean Baptiſte Tavernier ſtand on a far leſs queſtionable foundation. From contemplating and admiring his father's maps, he imbibed an irreſiſtible deſire to travel, and by ſubſequent travellers his name has been juſtly celebrated. See JEAN BAPTISTE TAVERNIER.

Philippe Thomaſſin was born at Troyes, in Champagne, in the year 1536. He went to Rome at an early age, and began engraving, like Hogarth and Sharp of England, by ornamenting with the graver and ſcorper the furniture of the table, and buckles and other articles of dreſs. He afterward placed himſelf for improvement under Cornelius Cort, and perhaps for a time under Cherubino Alberti. Huber ſays he ſtudied under the former, (who was now in high repute at Rome,) and Strutt, that "it is very poſſible he might actually ſtudy under the direction of the latter. He worked with the graver only, in a ſlight, but clear and firm ſtyle. There is, however, a ſtiffneſs in his execution, which being rendered more viſible by the total

want

want of effect in his prints, gives them a harſh unfiniſhed appearance. His drawing is rather mannered, than abſolutely incorrect."

Thomaſſin died at Rome at an advanced age, where he had the honour (for ſo it ſhould be eſteemed) of inſtructing Callot in the uſe of the graver; but a handſome lady whom Thomaſſin had married, and of whom he was jealous, was the means of preventing Callot from remaining long under his tutorage. His engravings conſiſt of more than two hundred plates, of which the ſubjects of fifty-two are the Italian antique ſtatues. Of the remainder, the principal are, "Philippe Emanuel de Lorraine, Duc de Mercœur," in folio, dated 1595. "Jeſus Chriſt and the Apoſtles," after Raffaelle, on fourteen folio plates. "Saint Margueritia, holding a Palm in her Hand, with her Foot on the Wing of a Dragon," from Raffaelle, in folio, 1589. "Saint Cecilia, and four other Saints," from Raffaelle, in folio, 1617. "The School of Athens," after Raffaelle, wherein he has changed the philoſophers Plato and Ariſtotle for St. Peter and St. Paul, large folio. "The Doctors diſputing reſpecting the Holy Sacrament," from the celebrated picture in the Vatican by Raffaelle; a large plate, dated 1617. "Saraſin landing at the port of Oſtia," from Raffaelle. "Holy Family," after F. Zucchero, in folio. "The Adoration of the Kings," after F. Zucchero; a large plate, upright in form, and arched at the top. "Miracle of Jeſus at Cana," from F. Zucchero, folio. "The Nativity," from Ventura Salembini. "The Purification of the Virgin," from Barroccio. "The Four Martyrs," after B. Paſſari, in folio. "The Laſt Judgment," from F. Vanoi, in folio. "Allegory of the Redemption." Here the virgin is ſeen in the clouds interceding for the patriarchs; from Vaſari, folio. "Apollo with the Muſes dancing around him," from Balthaſar Peruzzi; a large print, in the form of a frieze, engraved on two plates, and dated 1615. The works of this artiſt are moſt of them marked with his name at length.

Thomas de Leu was born at Paris ſome time about the year 1570. He worked entirely with the graver, which he handled with much care. His ſtyle is neat and mechanically clear, reſembling that of the Wierixes; and his works conſiſt chiefly of portraits of the celebrated characters of his time, of which ſeveral are engraved after his own drawings, and the reſt from the pictures of Bunel, Caron, Rubel, and Quenel.

Of his hiſtorical works, which amount but to very few, we are only able to enumerate an "Ecce Homo," attended by angels bearing the ſymbols of the paſſion; "The Twelve Sybils," deſigned by himſelf; "The Life of St. Francis," in twenty-five plates; and "Juſtice rewarding the Labours of the Huſbandman," from Frederic Zuccaro. His principal portraits are of the following perſonages:

Henry de Bourbon, prince of Condé, at the age of nine, dated 1595. Céſart Monſieur, aged five years. Henri III. king of France and Poland. Mary Stewart, queen of France and Scotland. Charles de Bourbon, count of Soiſſons. François de Bourbon, prince de Conty. Anne duke of Joyeuſe, admiral de France. François de Bone, lord of Leſdigueres. Charles de Goutant de Biron, mareſchal de France. Charles de Gonzague, duke of Nivernois. Charles de Lorraine, duke of Maine. Henri de Savoye, duke of Nemours and of Genevois. Henri de Montmorency, conſtable of France. Louiſe de Budos, the ſpouſe of the former. Louiſe de Lorraine, dowager of France. Louis Serven, advocate-general. Jean Paſſerat, a learned man and a poet, repreſented in profile. from having loſt an eye. Franciſcus Ranchinus, profeſſor medicus. Bonus de Broe, Turnonenſis, ſacerdos et abbax. 1588. Buſt of Henry IV. after Bunel, folio. Buſt of Henry III. and Marie de Medicis, after J. Quenel, in folio. Marie de Medicis, princeſs of Florence, and M. Nicholas de Neufoille; the laſt of which, in the opinion of Strutt, is a fine ſpecimen of his ability in portrait engraving.

The prints by this artiſt are commonly inſcribed either Thomas, or Th. de Leu fe. et exc.

Louis Buſinck was born in France toward the cloſe of the ſixteenth century, and practiſed that mode of engraving on wood which had been invented almoſt a century before by Mair, or by Hugo da Carpi, and was technically termed engraving in *chiaro-ſcuro*. Three blocks of wood are ſucceſſively impreſſed on every print produced in this manner. The firſt for the outline; the ſecond for the deeper ſhadows; and the third for the demi-tint. See WOOD ENGRAVING.

Buſinck practiſed this mode of art with conſiderable ſucceſs. He probably learned it in Germany, for we find him, according to Heinnekin, engraving at Minden, about the year 1630, in concert with George L'Allemand.

His ſtyle of engraving is broad, bold, maſterly, and in all reſpects ſuperior to that of his coadjutor. Heinnekin adds, that before he quitted Minden for Paris he had executed the following ſubjects from compoſitions of his own.

"Fidelity," an allegorical piece, dated 1630, in folio. A Man, half-length, 1630, folio. A Cavalier on foot, 1630. A Peaſant with a wallet. Another Peaſant carrying a pitcher.

The following, which are alſo in clare obſcure, (or chiaro-ſcuro,) are from the deſigns of L'Allemand.

"St. Peter holding the Keys," in 4to. "The Apoſtles, John and Matthew, in folio. "Judith with the Head of Holofernes," in folio. "Moſes ſitting with the Tables of the Law," in folio. "A young Man with a Plume in his Hat playing on aFlute," in folio. "Æneas reſcuing his Father Anchiſes and his Family from the burning of Troy," an upright, in folio.

L'Allemand, the coadjutor of Buſinck, was alſo a native of France, and, according to abbé Marolles, was born at Nancy. Papillon, from the information of his father, ſays that he reſided at Paris, where he expended ſuch conſiderable ſums in conſtructing preſſes and other machinery of his own invention, for printing chiaro-ſcuro engravings on wood, as much impaired his circumſtances. To which Strutt adds, that he made a great number of drawings to be engraved in that manner, many of which he engraved with his own hands; "and when one ſees how indifferently they are done, his want of ſucceſs is not ſurprizing."

Francois Perrier was born at Macon in Burgundy, in the year 1590, and died at Paris in 1660. He painted and engraved in chiaro-ſcuro, and alſo performed ſome etchings on copper. Under what maſter he learned the firſt rudiments of art is not known; but he went to Rome early in life, where, though he ſubſiſted with difficulty, he ſtudied hard. His drawings from the antique ſtatues and baſſo relievos recommended him to the notice of Giovanno Lanfranco; and under the direction of that admirable artiſt he purſued his ſtudies with better encouragement, and more ſucceſs.

After a long ſtay at Rome, he returned to his native country, and painted at Lyons the little cloiſter of the Chartreuſe; going from thence to Paris, he there engaged himſelf with Simon Vouet; and his reputation continued to increaſe.

In the year 1635 Perrier returned to Italy; and it was during his ſecond abode in that country that his beſt etchings were

were executed, particularly thoſe after the antique ſtatues and relievos.

The word genius, which is applicable to ſo few, has been perhaps too haſtily applied to the works of Perrier. Without denying him the merits of facility and ſpirit, we have ſtill to learn, in what reſpect he extended the former boundaries of his art. His etchings are coarſe and incorrect; the heads and extremities of his figures are neglected, and his facility is not the facility of feeling. In his works from the antique, he has left behind the exquiſite preciſion of thoſe great models; and has given us little more than the attitudes and compoſitions. But his chiaro-ſcuro engravings on wood are entitled to much higher praiſe, and are more juſtly eſteemed by connoiſſeurs.

Whilſt Perrier remained in Italy, he Italianized his name, and the etchings he performed there accordingly bear the ſignature of *Paria*. His cypher, compoſed of an F and a P, will be found in our plate of thoſe of the French ſchool, to which he ſometimes added the letter B, denoting that he was a native of Burgundy.

Of his numerous engravings, we ſhall begin with mentioning the beſt of thoſe which are after his own pictures and drawings.

"A Holy Family," or the infant Jeſus and St. John, in folio. "Flight into Egypt," in folio. The Holy Family are here repreſented as paſſing a river. "Chriſt with the Virgin in a Swoon at the Foot of the Croſs," in folio. "St. Roch curing the Plague," in folio. "The Body of St. Sebaſtiana," in folio; inſcribed at length Franciſcus Perrier Burgundus, inv. et ſ. 1633. It is a ſort of apotheoſis of the ſaint, in which are repreſented ſaints and angels with the palm and crown of martyrdom. "Venus with the Loves and the Graces," in folio; this is inſcribed Fr. Paria Borgog., and is of the proportions of a frieze. "Time clipping the Wings of Love," in folio. This is engraved in chiaro-ſcuro, and is a performance of great merit; certainly one of the very beſt works of the maſter. It is accompanied by the following Latin motto:

"Omnia vincit amor, vincit mox tempus amorem."

Of the plates which he has engraven from the antique ſculpture, and compoſitions of Italian and French painters, the following will probably be eſteemed among the beſt. A ſet of the antique ſtatues conſiſting of an hundred plates, in folio. Another ſet conſiſting of fifty plates of the bas reliefs of Italy, in folio. The Angles of the Farneſe gallery, ten plates. "The Aſſembly of the Gods, and the Nuptials of Cupid and Pſyche," a pair of the frieze form, after Raphael. "The laſt Communion of St. Jerome," a middle-ſized upright plate from A. Carracci. "The Nativity of Jeſus Chriſt," from S. Vouet, folio. Portrait of Simon Vouet, ſurrounded by an hiſtorical border, in folio; dated 1632.

Guillaume Perrier, (the younger,) who died in 1655, was alſo born at Macon, and is ſuppoſed to have been the younger brother of Francis, from whoſe deſigns he executed ſeveral plates, imitating his ſtyle of etching, but with no great ſucceſs.

Auguſtin Garnier, (whom Strutt miſtakenly calls by the name of Antoine,) was born at Paris in the year 1592, and was living in the time of the abbé Marolles, but the year of his death is not known. He etched his plates with a broad and bold line, and finiſhed them with the graver; there is conſequently a certain firmneſs and facility in his ſtyle, yet the heads and extremities of his figures are ſomewhat heavy, and his outlines hard and incorrect. His principal works are, twelve plates from thoſe pictures of Primaticcio, which are in the chapel of the palace de Fleury at Fontainbleau. "A Holy Family," "St. John the Baptiſt," and "Charity," all in folio, after J. Blanchard. "The fainting St. Sebaſtian, relieved by Women," from the ſame painter, and alſo in folio.

He moreover engraved ſome few plates from Pouſſin, M. A. Carravaggio and other maſters, on which his monogram appears, for which ſee our plate of the cyphers, &c. of the engravers of the French ſchool.

Jean de Courbes was alſo a native of France, and born about the ſame time with A. Garnier. He engraved chiefly for the bookſellers. His works are little known or noticed, and do not deſerve to be noticed more.

At one period of his life he was in England, and engraved here the portraits of ſir Philip Sydney, and the counteſs of Pembroke, which are inſcribed J. de Courbes fecit.

It is merely on the authority of Huber and Roſt, that this artiſt is here ſtated to have viſited England. The preſent writer is inclined to doubt the fact, and rather on account of the poetry which is engraved beneath theſe portraits, being in the French language.

The verſes under that of ſir Philip are as follow:

"Sidney, dont voicy le viſage,
Scent joindre également les armes et les arts,
Et mit tous les deux en uſage,
Sur le mont d'Apollon, et dans le champ de Mars."

and are ſcarcely leſs complimentary under the portrait of the counteſs:

"Pallas puruſt jadis en Grece,
Comme la beauté que tu vois,
Que ſeule euſt de cette Dieſſe
L'eſprit, le viſage, et la voix."

Claude Vignon practiſed both painting and etching. He was born at Tours in the year 1590, and died in 1670. He ſtudied a long time in Italy, imitating at firſt the ſtyle of Michel Angelo Carravaggio, and with ſome ſucceſs; but he afterwards fell into a manner of his own, more expeditious, but rough and unfiniſhed.

Of his etchings, which diſplay the hand and mind of a maſter, the abbé Marolles poſſeſſed two hundred and ſeventeen, of which the following may be numbered among the beſt.

A ſet of thirteen from the life of Chriſt, in ſmall quarto. "St. John in the Deſert." "St. Philip baptizing the Eunuch of Queen Candace." "The Martyrdom of St. Andrew." "The Aſſumption and Coronation of the Virgin," inſcribed Cl. Vignon inv. et fecit, Romæ.

Jaques Callot was born at Nancy, whilſt Lorraine was yet an independent dukedom. He is by ſome authors reckoned among the engravers of the French ſchool, but as he ſtudied at Rome and at Florence, and exercifed his art chiefly at the latter city, his biography and works will be found in our account of the Italian ſchool of engravers.

Claude Audran is the patriarch of that family who created an era in engraving, and is therefore entitled to reſpectful notice in our account of the French ſchool. He was the ſon of Louis Audran, an officer belonging to the Wolfgang hunters, in the reign of Henry IV. and was born at Paris A.D. 1692. He did not take up the graver till rather late in life, and produced but few prints, but he was the father of Germain and Gerard Audran. From Paris he retired to Lyons, and died there in the year 1677.

Carl or Karl Audran was alſo the ſon of Louis, and was born in Paris, A.D. 1594. He diſcovered ſome taſte for engraving, and learned the uſe of his tools in his native country,

country, but afterward travelled to Rome for improvement, when he produced ſeveral prints that obtained him deſerved reputation, and at his return adopted that ſpecies of engraving which is performed with the graver only, imitating the ſtyle of Cornelius Bloemart.

But though he imitated Bloemart, he aimed at ſuperior neatneſs, and perhaps the prints of Lucas Kilian, and thoſe of the Sadelers, may have been the real foundation of his ſtyle.

On his return from Italy he ſettled at Paris, where he died in the year 1674, without having ever been married. He at firſt was accuſtomed to mark his prints with the letter C. but his brother Claude producing ſome engravings of inferior merit, marked with the initial letter only of his baptiſmal name, he ever after made uſe of the letter K, and wrote his name Karle.

The abbé Marolles, who ſpeaks of this artiſt with great praiſe, attributes an hundred and thirty prints to him. The following will probably be found to include the beſt of his works.

The portrait of Henry de Bourbon attended by the cardinal virtues, an oval, in folio, marked K. Audran ſc. The portrait of André Laurent, phyſician to Henry IV., ſmall oval. The portrait of Pierre Légier, with ornaments, ſmall folio. An allegorical ſubject, including the portraits of Nicolai de Neufville, marquis of Villeroy, and Charles de Neufville. A genius is repreſented as painting a third portrait, and on the palette is written "Unus ex duobus." Marked C. Audran fecit.

Hiſtorical and Emblematical Subjects.—A frontiſpiece to the gallery of illuſtrious women, conſiſting of twenty plates of celebrated women, after Pietro da Cortona. The work is in folio, and with each portrait is a repreſentation of that event in the life of the original, on which her celebrity is principally founded. "The Annunciation," a folio plate, engraved from the picture of Louis Carracci in the cathedral at Bologna, but falſely attributed, upon the plate itſelf, to Annibal. Strutt, who ſpeaks of it as being one of the beſt works of this engraver, has fallen into this error. The "Baptiſm of our Lord," a ſmall oval, after Annibal Carracci, without the names of the artiſts. "St. Francois de Paulo, in folio, after Melini, marked Carl Audran ſc. "The Stoning of St. Stephen," in folio, after Palme be Jene. "The Miraculous Conception," inſcribed "Amat hanc ſapientia matrem," after Jac Stella, in folio. "La Nativité de notre Seigneur," in folio, after the ſame maſter. King David is here introduced recording ſomething on a tablet. "St. Catherine devant la Sainte Famille," in folio, after the ſame, a beautiful piece, in which ſeveral angels are introduced. "The Holy Family," in folio, after Titian, an excellent work. It may be diſtinguiſhed from the numerous compoſitions on this inexhauſtible ſubject, by the following circumſtances. The Virgin Mary is receiving an apple from the infant St. John, St. Catherine is kneeling, and the back ground is a landſcape with ſhepherds and cattle. "La Vierge tenant l'enfant Jeſus," who is trampling on the ſerpent, in folio, after Giov. Lod. Valeſio, marked K. A. F. "Sujet de Theſe," in folio, after Cl. Vignon. This engraving repreſents religion as the true ſcience, and has a Latin inſcription. "St. Francois," in folio, after S. Vouet. The ſaint is repreſented as in an holy extacy before the ſacrament, and the print is inſcribed, Tergeminus in terris vincis. A Frontiſpiece to the book of Joannes Franciſci Niceronis Pariſini. "Ord. Minor. Thaumaturgus," in folio, after the ſame maſter. The ſubject is a genius holding the portrait of Cardinal Mazarin. "L'Aſſomption de la Vierge," in folio, after Dominichino. It is in a circle or a ſhort oval, is inſcribed Reginæ Triumphanti, and eſteemed one of the beſt engravings of Carl Audran.

Michel Laſne was born at Caen in the year 1596, but reſided chiefly at Paris, where he died in 1667. He worked entirely with the graver, and handled that inſtrument in a bold, open ſtyle, ſomewhat reſembling that of Bloemart, though Mr. Strutt believes that he choſe Villamena for his model. His execution is dry, and his drawing, eſpecially of the extremities, ſomewhat heavy. Laſne was induſtrious in his profeſſion, and, according to the abbé Marolles, the number of his engravings amount to about ſix hundred. He ſometimes marked his prints with his name at length, and at others with the cypher, which will be found in our plate of the monograms, &c. of the French ſchool of engraving. The beſt of his works are enumerated below, beginning with thoſe *from his own compoſition.*

"Un Garcon Errant," inquarto. "Compagnie de Payſans en bonne humeur," in quarto. "La Vierge," with the infant Saviour ſleeping under a tree, in folio. "A dead Chriſt mourned by the Magdalen," in folio, dedicated to Lewis XIII. and dated 1641. "Bellerophon monté ſur Pegaſe combat le Cheymere," in folio.

Hiſtorical, after various Maſters—"Sainte Famille," after Rubens, in folio, and very rare. The infant Chriſt is repreſented as careſſing his mother, and St. John introduced by Joſeph, is followed by his lamb. "St. Frances d'Aſſiſe receiving the infant Chriſt from the Virgin Mary," an upright folio, after Rubens. This plate is executed in a much neater manner that his other engravings, but bears the name of De Laſne.

"St. Francis de Paul receiving the Infant Chriſt from the Hands of the Virgin," from the ſame painter. "La Viſitation de St. Elizabeth," in folio, after L. Carracci, but falſely attributed to Annnibal. "La Vierge, et l'Enfant qui dor," in folio, after a celebrated picture of Annibal Carracci. This is in England commonly called "The Silence." It repreſents the infant Saviour ſleeping, and the Virgin holding up her finger as St. John approaches, and has been ſubſequently engraved by Picart, by Hainzelman, and by Bartolozzi. "Ecce Homo," in folio, after Titian. "Jeſus Chriſt dans ſa Gloire," in folio, after Paul Veroneſe. The Saviour is here accompanied by St. Peter and St. Paul. "The Virgin ſeated on a Creſcent," an oval, in folio, after Albani.

Laſne alſo engraved the following portraits, chiefly after his own drawings

Michel Aſénus, Sculptor Regius, in folio. Louis XIII. on horſeback, proclaimed by Fame, and Bernard, duc de la Valette, alſo on horſeback, its companion. In the back-ground of the former is repreſented the battle of Veillance, and in that of the latter the town of Metz: both of which back-grounds are engraved by Callot. Anne of Auſtria, queen of France, a whole length figure, in royal robes, folio. Arnaud, cardinal duc de Richelieu; folio. Julius cardinal of Mazarin, folio. Charles father of Crequi, marſhal of France, folio. Francis de Baſſompierre, marſhal of France, folio. Pierre Seguier, chancellor of France, folio. Nicholas de Bailleur, preſident of the French parliament, folio. Francis Fernandez, a friar of the order of St. Francis. Le pere Joſeph de Paris, a famous capuchin, folio. Louis Petit, General of the order of Trinity, folio. Jean Francois Mieron, a monk and celebrated mathematician; in folio, very rare. Julio Strozzi, the Venetian poet, in quarto, after Simon Vouet, dated 1627. Jean Charles Doria, quarto. Francois Queſtrel, firſt painter to Henry III., from a picture by himſelf; quarto. Le pere Nicholas Couſſin, folio, 1651.

Nicholas

Nicholas Chaperon was born at Chateaudun about the year 1596; he was educated a painter, and ſtudied under Simon Vouet, but afterwards preferred etching, of which his works chiefly conſiſt. Travelling to Rome for improvement, he was induced to remain there a conſiderable time, during which he produced a ſet of prints from thoſe pictures by Raphael, in the Vatican, which are called his *bible*. They conſiſt of fifty-two plates, which the preſent writer has not ſeen, but of which Strutt ſays, with ſome degree of inconſiſtency, that they "are chiefly eſtimable as being, upon the whole, the beſt copies of that noble work; but, however, the ſweet ſimplicity of ſtyle, and correctneſs of drawing, ſo manifeſt in the works of that celebrated painter, are totally loſt in the affected manner of the engraver. The heads are very indifferent in general, and the other extremities very poorly marked."

At his return from Rome, Chaperon eſtabliſhed himſelf at Paris, where he etched ſeveral plates in a ſpirited ſtyle, generally marking them with the initials of his name, and the addition of the letter F for fecit. Among them the following will be found worthy of preference on account of their merits:

The portrait of himſelf at the foot of the buſt of Raphael, in folio. This is generally prefixed to the bible mentioned above, and ſerves as its title-page or frontiſpiece.

Portrait of Henry IV. of France, at the age of forty-two, in a frame of antique ſculpture, beneath which the king, wounded by Du Chatel, is repreſented in bas relief. It is in folio, after Freminet, and bears not even the initials of Chaperon, but is known to be from his hand. This is a very rare print.

Another portrait of the ſame monarch, at the age of forty-four, beneath which a battle is repreſented in the ſame manner as in the above.

"Une Vierge conſiderant l'Enfant Jeſus en lui preſentant le Sein," in folio, after his own compoſition, as is ſuppoſed by Roſt and Huber, though bearing the name of Titian. Yet it is difficult to believe that Chaperon, or any man would have expoſed himſelf to the unpleaſantneſs of ſuch frequent enquiries after the original as muſt be the neceſſary conſequence of a forgery of this nature.

"An Holy Family," in folio, where the virgin mother is ſuckling the infant Chriſt. "L'Alliance de Bacchus et Venus," in folio; dated 1659. "Bacchus a qui un Homme preſente a boire," folio. "Bacchus accompagne d'un Homme qui porte un Enfant," folio. "Famille de Satyres," a ſmall upright folio. This is a bold and ſpirited etching, and one of the beſt works of the maſter. "Bacchanale," where a child is pouring forth wine for a Bacchante, in folio. Another Bacchanalian ſubject, where Silenus is introduced, mounted on a he goat, in folio. Another, where a young Bacchante is mounted on a ſhe goat, in folio. Another, where a child is ſucking a ſhe goat, which a ſatyr is holding, dated 1639.

Pierre Brebiette was born at Mantes on the Seine. He was contemporary with Chaperon, and like him eſtabliſhed himſelf at Paris, after travelling to Italy for profeſſional improvement. He executed a conſiderable number of ſlight ſpirited etchings, which prove him to have been an artiſt of fertile and active fancy. In compoſition he is agreeable and profuſe; and his figures are well grouped, though not correctly drawn. Moſt of his prints are from his own pictures and deſigns, though he alſo etched ſeveral after Raphael and other maſters. He ſometimes marked his engravings with his name at length, and at others with his initials encloſed in a heart, and ſurmounted by a figure reſembling the numeral 4, as ſeen in our plate of the monograms uſed by the French engravers. The ſubjects of his principal etchings are:

His own portrait encloſed in a border, ſupported by two angels, in quarto; entitled "Peter Brebiette, Calcographus."

That of Francis Queſnel, the painter, ſupported by allegorical figures of Painting and Fame.

A ſet, or book of various prints, under the title of "Opera diverſa à Pierre Brebriette inventa," in quarto, dated 1658. "The Nativity," in quarto. "The Adoration of the Magi," in quarto. This is an unfiniſhed plate, and without the name of the artiſt. "The Virgin Mary with the Infant Chriſt aſleep," in quarto, dated 1638.

The Miraculous Conception itſelf ſeems ſcarcely more miraculous than that of the infinitely varied and numerous compoſitions to which theſe divine germs have given intellectual birth. When the vaſt number of engravings and pictures of the Holy Family and Virgin and Child are contemplated, it really appears as if by ſome divine preſcience, the ſubject itſelf were inexhauſtible, and as if the mental act of comparing their various beauties and merits were deſtined to baffle human ſuſceptibility and judgment. Brebiette has engraven three more plates of the Virgin and Child, in folio; in the firſt of which the infant Chriſt is crowned; in the ſecond, the virgin mother appears on her knees near the Saviour, and attended by two angels; and in the third, ſaints are adoring her.

"The Converſion of St. Paul," without the name or cypher of Brebiette, in folio. "The Martyrdom of St. Catherine," in quarto. "The Martyrdom of St. Sebaſtian," in quarto. "The Death of Niobe's Children," an upright. "Orpheus ſurrounded by the Brutes," in quarto. An Arcadian ſubject with ſatyrs, in quarto. "Les Quatrains du Sieur de Pibrac," dated Paris 1640. "The Four Seaſons," in ſmall ovals.

The following are in the elongated form of friezes.

"The Battle of the Lapithæ and Centaurs," "Thetis at her Toilette;" "A Sacrifice to Ceres." A ſet of twelve Bacchanalian ſubjects; and a ſet of four, repreſenting ſea-gods, in folio.

After other painters, Brebiette has engraved the following plates:

"An Holy Family," wherein the infant St. John has his foot upon a cradle, an upright in quarto, after Raphael. Another Holy Family, after Andrea del Sarto, in quarto. "The Martyrdom of St. George," after Paul Veroneſe, in quarto. "Paradiſe," after a grand compoſition of old Palma, engraved on two plates, and one of the very beſt of the works of Brebiette.

Jacques Stella was born at Lyons in the year 1594, and was the ſon of Francis Stella, a native of Flanders, but who had ſtudied the arts of portrait and landſcape painting in Italy. He loſt his father at the age of nine years, but was already inſtructed in the rudiments of drawing. At the age of twenty Jacques went to Italy, and entered the ſervice of that diſtinguiſhed patron of art, Coſmo de Medicis, from whom he enjoyed a penſion equal to that which had been granted to Callot, though far his inferior in merit. After remaining at Florence about ſeven years, he purſued his journey to Rome, which had been the prime object of his travels, where he ſpent eleven years in ſtudying Raphael, Pouſſin, and the bright exemplars of ancient and modern art which then abounded in that far-famed metropolis.

In the year 1634, he removed to Paris, where Louis XIII., hearing of his merits, aſſigned him a handſome penſion, and apartments in the Louvre, which induced him

to abandon a journey he had projected into Spain, and to ſettle at Paris, where he was ſoon after honoured with the order of St. Michael.

In the ſtyle of his art Stella is tame, and without energy, though he poſſeſſes ſome portion of grace, and details his forms with conſiderable academical knowledge. He was more of a painter than an engraver, and his beſt productions are his ſmaller pictures of paſtorals and children's ſports, though theſe are not free from the reproach of languor and inanimation. He generally marked his engravings, which are chiefly performed with the point and aquafortis, with a ſtar, a ſort of pun upon his own ſurname, as is exemplified in our plate of the marks, &c. of the engravers of the French ſchool.

Stella's etchings, which are not very numerous, are from his own compoſitions. The principal of them are, "The Deſcent from the Croſs," in folio, and "The Ceremony of doing Homage to the Grand Duke of Tuſcany, on St. John's day," a large plate, dedicated to the emperor Ferdinand II., and dated in the year 1621.

This artiſt died at Paris in the fifty-firſt year of his age, and his death is ſuppoſed to have been haſtened by too cloſe application to his ſtudies.

Etienne, or Stefan Baudet, was born at Blois, A.D. 1598, and died at Paris in the year 1691. He acquired the rudiments of engraving at Paris, but afterwards, as was the cuſtom of his age, travelled to Italy for improvement. He varied the ſtyle of his engravings at different periods of his life; and connoiſſeurs eaſily diſtinguiſh between thoſe prints which he engraved before, and thoſe which were produced after, his return from Italy. His earlier works were executed entirely with the graver, and though ſufficiently neat, are cold, mechanical; and as a French author ſays, "the manner accuſes the metal." In his ſubſequent ſtyle, he mingled etching with the work of the graver, and roſe decidedly ſuperior to his former ſelf. From a certain degree of reſemblance being traceable between this ſecond ſtyle and that of Jean Baptiſte de Poilly, ſome of his biographers have inferred that he imitated that celebrated engraver, without reflecting that Jean Baptiſte could have been but a youth when Baudet produced the engravings in queſtion.

This artiſt alſo occaſionally engraved in the taſte of Claude Mellan, who was his contemporary; and in the courſe of a long life he produced a conſiderable number of plates, from which the following are ſelected as the moſt favourable ſpecimens of his abilities. In his firſt ſtyle, according to Mr. Strutt, (who however appears to be miſtaken in ſome of his dates reſpecting this artiſt,) are

"The Tribute Money," a middling ſized plate, nearly ſquare, from Valentino, which (ſays this author) I think the moſt maſterly of thoſe which he executed in this manner. Four large landſcapes lengthways with figures, from Albano, publiſhed at Rome in 1672. The figures in theſe are from the hiſtory of Venus and Adonis. "The Four Elements," large circular prints, from the ſame maſter, dated 1675, (though according to Strutt they are not dated till twenty years after); and "The Martyrdom of St. Stephen," a large folio plate from Annibal Caracci's celebrated picture in the cabinet of the king of France; publiſhed in 1677.

In his ſecond ſtyle, according to the ſame writer, are, "Moſes trampling on the Crown of Pharaoh," a large folio, from Pouſſin's picture in the Louvre. "Moſes ſtriking the Rock," and "The Iſraelites worſhipping the Golden Calf," both in folio, and from the ſame maſter. "The Holy Family," from Pouſſin's original in the gallery of the Louvre, in folio; and "Venus repoſing after the Bath," in folio, and from the ſame painter, publiſhed 1666. The following large hiſtorical landſcapes, adorned with figures, are alſo from the Pouſſins. A ſet of four, dedicated to the prince of Condé, and publiſhed in 1684; and another ſet of four, dedicated to the king of France.

From the deſigns of other painters, according to the catalogue of Huber and Roſt, Baudet has engraven the following plates, *viz.*

"An Holy Family," from Sebaſtian Bourdon, in a circular form, and where angels and the infant St. John are adoring our Saviour. "The Adoration of the Shepherds," after Jac. Blanchart, in folio. "The Deſcent from the Croſs," after Annibal Caracci, in folio. "The Communion of the primitive Chriſtians," after Charles de la Foſſe. A ſquare plate after Valentino, entitled "Le dernier de Ceſar." A ſet of ſix grand folio landſcapes, after Sebaſtian Bourdon. A ſet of ſix, five only of which are by Baudet, of the grand ſtaircaſe at Verſailles, after Le Brun, the originals of which no longer exiſt; (N.B. the ſixth plate, which is of the cieling, is engraved by Ch. Simmonneau;) and "Adam and Eve diſmiſſed from Paradiſe," after Dominichino, from a picture in the king of France's cabinet; which engraving is eſteemed the chef d'œuvre of Baudet.

Beſide hiſtory and landſcape, this artiſt has diſtinguiſhed himſelf by engraving ſome of the ſtatues in the royal garden at Verſailles, in which he has imitated the ſingle-ſtroke ſtyle of Mellan; and the following portraits are alſo from his graver, and are all of the folio ſize. Pope Clement IX. Charles Perault, comptroller-general of the royal buildings, after Le Brun, dated in 1665, and inſcribed "Stef. Baudet ſc. Acad. Reg." Louiſa ducheſs of Portſmouth, as Venus, careſſing a dove, after H. Gaſcar. Antique buſt of a Roman lady of the reign of Adrian, from an original in the Thuilleries, and another antique buſt of the emperor Adrian himſelf, alſo from an original in the Thuilleries, dated in 1678, and executed in the ſtyle of Mellan.

Simon Guillain was a ſtatuary, and occaſionally an architect, but who having performed at leaſt an hundred etchings, is commonly reckoned among the French ſchool of engravers. He was born at Paris A.D. 1599, and died in the ſame city, according to the French authorities, in 1679; though, according to Strutt, he died in the year 1658. His father was a ſculptor of Cambray, under whom he made conſiderable progreſs in art before he travelled to Italy. On his return to Paris, he executed, among other works, the baſſo relievos and bronze figures to the memory of Louis XIII. in the angles of the "Pont au Change" at Paris: the figures in the niches of the portal of the Sorbonne, and thoſe which ornament the Maitre Autel des Minimes de la Place Royal, are alſo from his chiſel.

The following ſlight, but maſterly etchings, are not leſs creditable than his ſculpture, to the general ſtock of his talents as an artiſt.

A ſet of twenty plates from the life of St. Diego, from the originals of Annibal Caracci and Albano, in the church of the Spaniards at Rome; and a ſet of eighty ſmall uprights, entitled the Cries of Bologna, alſo after Annibal Caracci, with his life and portrait appended.

Charles David was born ſome time about the commencement of the ſeventeenth century. He was a native of Paris, but under what maſter he ſtudied engraving his biographers have not mentioned. Strutt ſays of him, with much truth, that "his ſtyle of mechanical execution ſeems to have been founded on an examination of the works of ſeveral artiſts, rather than a direct imitation of any one. He worked entirely

with the graver, in a clear, neat manner, but with great freedom of hand; he often rendered the effect of his prints leſs pleaſing than it otherwiſe would have been, by croſſing his ſecond ſtrokes too ſquarely upon the firſt. He certainly drew the human figure with a conſiderable degree of correctneſs; but he was apt to overcharge his forms, and mark the outlines of his muſcles too powerfully. His extremities eſpecially are, in general, rather heavy and defective. His lights, a fault uſual with the engravers of that age, are too much ſcattered, and too equally powerful: yet his beſt prints are deſervedly held in great eſtimation. He engraved "The Labours of Hercules," a ſet of twelve ſmall folio plates from F. Floris. "The Cries of Rome," a ſet of ſixteen ſmall upright folios, copied ſo faithfully from Villamena, that it is not eaſy to know the difference apart from the originals. "The Virgin and Child ſurrounded by Angels," an upright 4to. after Champagne. "La Vierge nouriſſant St. Bernard de ſon lait," and another 4to. frontiſpiece from the ſame painter. A ſet of landſcapes after Paul and Matthew Brill. An Ecce Homo. "The Gay Nurſe and Companion," from his own deſigns; and a ſingular print of a man with a ſnail upon his finger, accompanied by a he goat with a crown of ſnails upon his head, while a diſh full of them is ſeen on a table, after Callot. This latter is a very rare print.

Jerome David was brother to Charles, and worked in the ſame ſtyle, though with talents ſomewhat inferior: he went to Italy, and followed there the profeſſion of engraving till toward the middle of the ſeventeenth century, but the dates of his birth and death have not been recorded.

He uſually ſigned his engravings "H. David." The letter H ſtanding for Hieronymus, which is the Latin for Jerome. The author of the "Series of Engravers," publiſhed at Cambridge, not attending to this circumſtance, has ſpoken of his works as if they were executed by two artiſts, Jerome, and H. David. In ſome inſtances, however, his engravings are marked only with his monogram, for which ſee our plate of cyphers, &c. of the French engravers.

The following liſt, which begins with his portraits, will be found to include the beſt engravings from the hand of this artiſt, the number of whoſe plates, added to thoſe of his brother Charles, amount to about two hundred and twenty.

Charles I. of England; Henrietta Maria, his queen; Anne, queen of France; Gaſton, duke of Orleans; and Cardinal Richelieu; are all whole length equeſtrian portraits, in folio, and the laſt a very rare print.

A ſet of forty-two plates repreſenting the churches, tombs, and altars of Rome: theſe are etchings, and are after the drawings of Jean Baptiſte Montano, a celebrated chaſer of Milan, who died in 1621, and whoſe portrait (in folio) Jerome alſo engraved.

A ſet of thirty-ſix heads of ancient philoſophers, from deſigns of his own, engraved in a coarſe, dark ſtyle, in 4to. "A Landſcape, with Adam tilling the Earth after his Expulſion from Paradiſe." "An Ecce Homo," a ſmall upright folio, from Guercino. "The Virgin of the Roſary," a ſmall upright folio, after Guido, dated 1633. "The Virgin and Child," a ſmall circle, after Guido. "The Aſſumption of the Virgin," after Camillio Procaccini. "St. Francis de Paul walking on the Sea," an etching after Robert Picou.

Contemporary with the Davids was Jean Ganieres, an engraver of very ſlender abilities, who was a native of France, and reſided at Paris. His beſt works are portraits, and the beſt of his portraits are thoſe of Louis XIII. of France, a ſmall oval, ſurrounded with ornaments, and dated 1640. Cardinal Flavio Chigi, a ſmall upright; and M. de la Melleraye, in 4to. dated 1679. He alſo engraved "A Boy ſleeping, with a Skull lying near him," a ſmall plate, dated 1640. "A Magdalen," in folio, after Jacques Blanchard, beſides ſome other plates from the ſame painter.

Francis Tortebat, an artiſt of far ſuperior merit, was born at Paris in the beginning of the ſeventeenth century, and died in the ſame city in the year 1690. He was the ſon-in-law and pupil of Simon Vouet, from whoſe pictures and deſigns he etched ſeveral of his plates.

His etchings are ſomewhat rough, but are performed with great ſpirit; and he frequently produces a good chiaroſcuro.

In the year 1663 he became a member of the French Royal Academy, and from his etching-needle may be enumerated the following ſubjects.

The anatomical figures of Jean de Calcar, from the wood engravings which accompany the treatiſe of Veſalius. An emblematical figure in folio, after Vouet, in which an angel is repreſented piercing with an arrow a flaming heart, from the ſame painter, and of the ſame (folio) ſize: he has alſo engraven as follow: "Peace deſcending on the Earth;" the "Aſcent of Elijah;" "Sampſon recovering his Strength, and deſtroying the Philiſtines;" and "The Apotheoſis, or Beatification of St. Louis."

The French writers reckon Jacques Blanchard and Claude Gelee, who both lived at this period, among their ſchool of engravers, though with no very ſtrict propriety, as neither of them contributed to the advancement of that art, and both were very diſtinguiſhed painters.

Blanchard, as well as Claude, performed a few etchings from his own compoſitions; of which thoſe which are moſt deſerving of notice are, "An Holy Family," in 4to. publiſhed by Huart. Another "Holy Family," publiſhed by Cartres. The "Nativity of the Virgin;" and "St. Agnes worſhipping the infant Chriſt," after Caracci.

For an account of Claude ſee our biography of him as a painter. Yet the curious may not be diſpleaſed to be informed that the following etchings are from the needle of this very diſtinguiſhed artiſt. They are after his own pictures, and of courſe are not without merit, though they bear the marks of a hand unpractiſed in the art of etching. Two folio landſcapes with ruins and cattle. Two 4to. landſcapes; one a ſea-port with mariners; the other a paſtoral ſcene with figures dancing. A ſet of twenty-eight landſcapes, which are highly eſteemed among connoiſſeurs, and the "Via ſacra detto Campo Vaccino di Roma," in folio, dated 1636.

Claude Mellan was born at Abbeville, in Picardy, A.D. 1601; of which city his father was receiver of the cuſtoms, and paid great attention to the education of young Claude. His genius for drawing diſcovering itſelf at a very early period of his life, it was thought proper to ſend him to Paris, where he became the pupil of Simon Vouet, a painter who was highly celebrated at a time when falſe criteria of excellence obtained, having had the honour of inſtructing the king of France, the grand monarque himſelf! in the arts of deſign.

Thus ſays Strutt; but the French writers, with more probability, and indeed with better opportunities of aſcertaining facts of this kind, ſay that from Paris young Mellan was ſent to Rome, and *there* attended the lectures of the celebrated Vouet. Now at the time Mellan was ſixteen years of age, which is the period at which he is ſaid to have travelled to Italy, Vouet was preſident of the Roman Academy of St. Luke, and did not return to Paris till the year 1627, when he was ſummoned home by Louis XIII.

for the decoration of his metropolis. After performing, with tolerable ſucceſs, a few imitations of the pictures of Vouet, Mellan relinquiſhed the art of his preceptor, and dedicated his attention ſolely to engraving, in which he ſoon made conſiderable proficiency. He worked chiefly from his own deſigns, and manifeſted great power over the inſtruments of his new art.

Of the ſtyle of his engraving, as it varied at different periods of his life, we ſhall preſently ſpeak: that of his deſign is marked by a certain aſſumed briſkneſs in ſome figures, contraſted by the uneaſy languor of others; and his expreſſion partakes, in moſt inſtances, of that ſophiſticated confidence which properly belongs to the French hiſtorical art of the ſchool of Vouet.

Moſt of the plates which Mellan engraved in Italy, (where he appears to have remained upwards of thirty years, and where, among numerous other works, he produced his prints from the Juſtinian gallery, the portrait of pope Urban VIII. and that of the marquis Juſtinian,) are executed with the graver alone, and in a manner not materially differing from that in which the graver had been employed by other artiſts: that is, with parallel or converging courſes of curved lines, croſſed with ſecond, and occaſionally with third courſes of lines, as the degree of ſhade, and texture of the ſurface to be expreſſed, might require; but after his return to Paris he invented a new mode of working with ſingle ſtrokes only; working out his chiaro-ſcuro by re-entering his original courſe of lines until they became of the breadth and depth which he deemed neceſſary to his effect. Our countryman, Strutt, in commenting on this novel and ſingular ſtyle, ſays, "In ſingle figures and ſmall ſubjects he ſucceeded very happily; but in large compoſitions, where great depth of ſhadow was required, he has failed, and that in proportion as the force of colour (depth of ſhade) was wanted. Beſides, in ſubjects where ſeveral figures occur, the ſameneſs of ſtyle, which neceſſarily appears in every part of the plate, fatigues the eye, prevents objects from relieving each other, and adds greatly to the flatneſs of effect." The truth is, that he has not failed from the cauſes which Mr. Strutt has aſſigned; for it would have been very eaſy to have produced much deeper tones than we ſee in the engravings of Mellan, by means of ſingle courſes of lines, which is proved by their having been ſo produced by other artiſts; but he has failed in the opinion of the judicious, becauſe this ſingle-ſtroke ſtyle was founded on novelty, and not on principle. The example of Mellan does but go to prove, among many others, that it is one thing to ſecure the approbation of poſterity, and another to obtain a little breathing-ſpace for the ſhort-lived monſters which faſhion has been known to engender upon fine art, in the purlieus of a French palace.

One of the moſt celebrated, and I will add, moſt juſtly celebrated, of the engravings of this artiſt, is his "Sudarium of Santa Veronica." The reader, if he be not "ſkilled in legendary lore," ſhould ſtop to be informed that Saint Veronica was canonized in conſequence of offering our Saviour, as he proceeded to Golgotha, ſweating under the burthen of the croſs, her handkerchief or napkin, and that the impreſſion of the divine countenance remaining on the drapery, was religiouſly preſerved, and well it might, as the moſt highly and juſtly valued relic belonging to the order of St. Face, or St. Veronica.

The engraving of Mellan, accordingly, repreſents the front face of Jeſus Chriſt, as large as life, and as if depicted or impreſſed on drapery. It is an upright folio plate, and is executed entirely by means of a ſingle ſpiral line, beginning at the extremity of the noſe, which is, as nearly as was practicable, the center of the engraving, and continuing, without intermiſſion, over the whole face and back-ground of drapery.

The ſuperceſſion of the ſcience which ſhould preſide over fine art, by the unprincipled novelties of faſhion, has been often and juſtly regretted. Before an artiſt prides himſelf on doing what no other man can do, he ſhould at leaſt be ſure that what he attempts is worthy of being accompliſhed. Yet perhaps Mellan did not himſelf ſo much miſtake means for end, as lead others into this error, from their inadvertently following his example. The ſingular ſtyle of his art, as exemplified in the Sudarium of St. Veronica, may find juſtification, or at leaſt excuſe, in the opinion of its admirers, from the reflection that a work, ſo novel and ſurpriſing, ſavours of the miraculous, and is ſo far analogous to its ſubject, and perhaps is, not without ſome plauſibility, addreſſed to the prejudices, if not to the underſtandings, of thoſe who have faith in the holy myſteries of the legend of St. Veronica. Moreover the feebleneſs of effect, which Strutt endeavours to account for, is here a merit, or at leaſt capable of being ſo conſtrued; for the impreſſion of the holy face thus left on the Sudarium of the Saint, might naturally be expected to be leſs vivid, than if St. Luke himſelf had painted it at his eaſel. Something, in theſe caſes, ſhould be left for the imagination.

The year of Mellan's return to Paris is not mentioned by his biographers. He married in that metropolis in 1654; and the king being made acquainted, and being pleaſed with his talents, beſtowed on him a penſion, and aſſigned him apartments in the Louvre, where he continued to reſide till the advanced age of eighty-ſeven, ſurrounded with honours and bleſſed with an excellent conſtitution, which exempted him from the diſeaſes uſually attendant on this late period of life; he enjoyed a competent fortune, and was greatly eſteemed by all who knew him. Florent le Comte ſays, that, "Charles the ſecond of England was ſo much pleaſed with his performances that he invited him to reſide in London, making him at the ſame time very advantageous offers; but the love of his country prevented his accepting them." He does not appear to have had any children; for his plates, at the death of his wife, became the property of his nephew. The ſubjects of the principal of them are as follow, beginning with ſuch of the allegorical and mythological as were invented by himſelf; "Phœbus paſſing the Zodiac," in folio. "Perſeus and Andromeda," 4to. "Venus ſeated on a Couch with her Doves," 8vo. "Hercules and Atlas," folio. A ſea-port whence is ſeen a rock, on which lies a book where are engraved the papal arms ſubſcribed, "Ibi confringes tamentes fluctus tuos," in folio. "The Reſignation of the Regency of France by the Queen-Mother, through the Hands of the Queen of Peace and Mother of God," in folio. "France ſeated at the Tomb of the Queen-Mother, and holding her Portrait," in folio. "Religion in a ſitting Poſture, pointing to a Man, kneeling before her." "St. Stephen diſtributing his Wealth to the Poor," in folio. "The Church Militant." In this piece, an angel is repreſented diſplaying the croſs to ſeveral perſons kneeling, in 12mo. A rural piece, in which are introduced a peaſant with a winnowing-fan, and a cow licking her calf, in 4to. An allegorical ſubject, in which is repreſented a naked female lying on a bed, having behind her a mouſe-trap, and before her ſeveral infantile genii, one of whom raiſes her leg, while another preſents her with a bunch of grapes, in folio. This print, which does not diſplay much ſpirit, is very ſcarce, and only half finiſhed. A frontiſpiece, for a collection of bon mots, repreſenting ſeveral ſatyrs, one of which is ſeated on a globe,

globe, having this inſcription: "ſic ſe ridendum dat deriſoribus orbis," 4to.

A political allegory from Antoine Talon, dedicated to cardinal Mazarin. This piece contains a figure repreſenting the adminiſtration, lying in an attitude of deſolation, and diſplaying in the diſtance ſcenes of horror which devaſtate the kingdom. Below, are two Hercules' preparing to bring ſuccour, and ſtill lower, are two figures writing, beneath which reclines a ſleeping Pallas, enchained by two youthful genii, with bands forming the initials of the cardinal's name. This ſcarce print is large, and is engraved on three plates.

Another allegory of the ſame ſilly kind, from Guill. de Longueil, dedicated to the ſame patron. Here Apollo is repreſented ſurrounded by the nine Muſes, who are occupied in pourtraying the arms, the initials, and the devices of the cardinal; and beneath are ſeen two rivers iſſuing from their urns, ornamented with feſtoons. This piece occupies two plates; and, like the former, is extremely ſcarce.

The following ſubjects are engraved from various maſters.

"Judith holding the Head of Holofernes," after Virginia de Vezlo, the wife of Vouet, in 4to. "Salomea carrying the Head of John the Baptiſt in a Charger," from S. Vouet, in 4to. "A Roman Charity," from the ſame, in 4to. "Lucretia," a folio plate publiſhed at Rome. "Pſyche and the ſleeping Cupid," Rome, in 4to. This piece is engraven with croſs lines, and in a very maſterly ſtyle. "The Virgin holding a Roſe, and the Infant Jeſus on her knee," from the ſame, dated 1633, in 4to. "St. Luke taking the Portrait of the Virgin," from the ſame, 1627, 8vo. "St. Francis de Paule contemplating the Heavens," from the ſame, Rome, in folio. "St. Catherine on her Knees, receiving from an Angel the Crown of Martyrdom," from the ſame, Rome, 8vo. "Genius, Memory, and Will," from Vouet, in folio. "The Eternal, in his Glory," with two figures repreſenting the old and new law. This is the frontiſpiece to the Louvre bible, from Pouſſin, in folio, without ſignature. "Horace crowned by Genius, while one of the Muſes preſents him with the Maſk of Satire," from the ſame, in folio. The frontiſpiece to the Louvre edition of Horace. "Virgil crowned by Apollo," from the ſame, in folio, without a ſignature. The frontiſpiece to the Louvre edition of Virgil. "The Courteſy of Rebecca, in her firſt Interview with Abraham's Steward," a folio engraving from Tintoret, eſteemed one of the fineſt hiſtorical prints of Mellan. "A View of a Palace in a Garden," a folio print after Pietro da Cortona, publiſhed at Rome.

His works from the Old and New Teſtaments are as follow: "Lot and his Daughters," in 4to. dated Rome 1629. "Sampſon betrayed by Delilah, who is cutting off his Hair," in 4to. The "Burning Buſh and Moſes," in 4to. dated 1663. The "Miraculous Fall of Manna," in 8vo. The "Annunciation," inſcribed "Ecce Virgo concipiet," a folio print, dated 1666. "The Madonna," in 8vo. in which the virgin is repreſented ſeated beneath a tree, with the infant Jeſus on her knees. Another of the ſame ſubject and ſize, dated 1659. Here Mary is ſeated at the baſe of a pillar, and, as in the preceding, ſhe holds the infant Jeſus on her knees. Another, in which ſhe is repreſented ſeated on a bank, with the infant Saviour ſtanding near her, and in the back ground St. Joſeph binding up faggots, while in the four angles are figures from the Old Teſtament. "A Holy Family," Rome, 1635, in folio. In this piece the virgin is ſeated near the ruins of an edifice, with the infant ſtanding on her knee. "A Group," conſiſting of St. Anne, St. Joachim, St. Joſeph, St. John the Evangeliſt, and St. Bernard. A buſt of the infant Chriſt. A buſt of the Virgin in her youth. A buſt of the Virgin, at a more advanced period of life, with her hands croſſed over her breaſt, 1650, in folio. "Chriſt in the Garden of Olives, and his Diſciples aſleep," in folio. This is a night-piece, and in ſome eſtimation among connoiſſeurs. "Chriſt led by the Soldiers," with this inſcription, "Pater ignoſce illis, quid faciant," in folio. "St. John, and Mary Magdalen, embracing the Croſs," Rome, in folio. "The Crucifixion," dated 1665, in 4to. "Chriſt expiring on the Croſs, with the Virgin, St. John, and Mary Magdalen embracing the Foot of the Croſs," in folio. "Jeſus Chriſt carried to the Sepulchre," during which the graves give up their dead. In one corner is ſeen written on a tomb, "Terra Mota eſt," 1678, in folio. "The Reſurrection of Jeſus Chriſt," inſcribed, "Per ſe refurgens," 1683, in folio. "The Fathers of the Church aſſembled in council," 1665, in folio. In this piece is ſeen a table, with an open book, in which the word "Evangelia" is inſcribed.

The number of ſubjects which this artiſt has ſelected from the rubrics of martyrology, as well as from the reigning whims of the minions of the French court, lead us to ſuſpect that he followed the taſte of the times in which he lived, and, careleſs or ignorant of the immutability of principle, merely and meanly rendered his art ſubſervient to the religion and politics of the hour. Thoſe which follow are from his own compoſition, as well as ſeveral of thoſe which we have juſt paſſed. "The Sudarium of St. Veronica," a large folio, of which we have already ſpoken. "St. Peter Nolaſque," in folio. The ſaint is borne through the air by two angels. This is the rareſt, and one of the beſt of Mellan's engravings. "St. Stephen in the Habit of a Deacon," in 4to. The ſaint is kneeling, and the following inſcription mingles with a radiance of light; "Ecce video Cœlos apertos." "Alexis in his latter Moments," in folio, dated 1649. "St. Bruno in the Deſert," an upright folio; four other folio plates lengthways, from the life of this ſaint; in the firſt of which he inveſts a brother of the order, in the ſecond, exhorts the holy brotherhood, in the third, enters the council, and in the fourth ſhews the hoſt to the military. "St. Ambroſe interdicting the Entrance of the Emperor Theodoſius into his Church," a folio plate dated 1681.

"St. Auguſtin converted in the Garden of Aleppo," 1660, in folio. "St. Bernard proſtrate before a Crucifix," in folio. "St. Cajetan kneeling before a Crucifix," 1664, in folio. "St. Dominic in a Trance," in folio. Beſides the principal perſonage in this landſcape, ſeveral monks are ſeen in the back ground. "St. Francis in the Deſert, kneeling before a Crucifix," 1638, in folio. "St. Francis de Paule," 1627, in quarto. "Pope Gregory writing to King Childebert," 1681, in folio. "St. John meditating in the Deſert," 1629, in folio. "St. Ignatius in a Trance," in folio. "St. Joſeph, (Joſeph Chriſti nutritie,)" in folio. "St. Peter at Prayers near a rock, a crucifix in the back ground," in folio. "St. Paul carried up into Heaven," with this inſcription: "Sive in corpore neſcio," 1674, in folio. "A Penitent Magdalen lying on a Mat, her Body lacerated by Thorns." "Mary Magdalen expiring, ſupported by Angels," Rome, 1687, in folio. "St. Genevieve, a young Shepherdeſs, ſeated in an Attitude of Contemplation, at the Foot of a Tree," 1680, in folio. "St. Claire kneeling before the Body of Chriſt," 1667, in folio. "A Nun at Prayers," 1647, in folio. "St. Thereſa kneeling in her Cell before a Crucifix," 1661, in folio.

The following portraits are chiefly engraved from the artiſt's own pictures and drawings.

Claude

Claude Mellan, painter and engraver, 1635, in folio. Pope Urban VIII., from Bernini, 1631, in quarto. Anne of Auſtria, queen of France, in weeds, in folio. Louiſa-Maria de Gonzague, queen of Poland, 1645, quarto. Cardinal Guido Bentivoglio, in quarto. Charles de Crequies-Leſdiguercy, Mareſchal of France, Rome, 1633, in quarto. Jean de Saint Bonnet, lord of Toiras, Maréſchal of France, in quarto. Claude Marolles, 1613, in quarto. This is the portrait of a Tourangeau gentleman, and one of the braveſt men of his age. Michel de Marolles, abbé of Villeloin, in quarto. This is the ſon of the former, and a great connoiſſeur in prints, whom we have ſometimes quoted. Francis de la Motte le Vayer, 1648, in quarto. Peter Gaſſendi, profeſſor royal of mathematics at Paris, in quarto. Henry duke of Montmorency, in quarto. Cardinal de Bouillon, 1613, in folio. This is a buſt of the cardinal on a pedeſtal. The illuſtrious Armand, cardinal duke of Richelieu, in folio. Cardinal Mazarin, gr. folio. Francis Villemonte, biſhop of St. Maloes, 1661, in folio. Pierre Seguier, chancellor of France, gr. in folio. This portrait is executed with much ſpirit. Nicholas Coćſſeteau, biſhop of Marſeilles, Du Mouſtier pinx. gr. folio. The celebrated cardinal de Perron, Herbin pinx. gr. folio. Victor le Bouthillier, archbiſhop of Tours, 1658. gr. folio. Joann Haberti Eq. T. D. de Montmor, Monument. D.D. Claude Mellan, &c. 1640, gr. folio. Henri-Louis Habert de Montmor, the ſon of Jean, 1640, gr. folio. Henrietta Maria de Baude Frontenac, the wife of H. L. Habert de Montmor, 1641, gr. folio. Henri de Meſmes, preſident of the parliament, &c. gr. folio. Pierre Molé, keeper of the ſeals, gr. folio. Abel Servien, treaſurer to the French Academy, gr. folio. Nicholas Claude Fabri de Peireſe, counſellor at Aix in Provence, gr. folio. This is one of the moſt beautiful portraits of Mellan.

Beſides the works above enumerated, Mellan executed ſtatues, antique buſts, and baſſo relievos, from the Juſtinian gallery, to the amount of 322; as well as the antique ſtatues and buſts of the royal palaces of France; but the latter, as has already been mentioned, were performed in concert with Baudet; they form altogether ſixty-one pieces.

Michel Corneille, the father, was born at Orleans in 1633, and died at Paris in 1664. He was a pupil of Simon Vouet, whoſe method he invariably followed in the pictures which he painted for different churches and palaces. He etched a few plates after Raphael, the Caracci, and Vouet, of which the following are moſt worthy of remark.

A Holy Family from Raphael, in quarto. In this piece, which has been often engraved, the Virgin is ſeated by the ſide of St. Elizabeth, while the infant Jeſus is taken out of the cradle, to be placed on the knees of his mother, and St. John is repreſented bringing ſome fruit.

"The Maſſacre of the Innocents," from the tapeſtries of the Vatican, by Raphael, in folio. "Jeſus appearing to Mary Magdalen, as a Gardener," or the "noli me tangere," from the ſame, in folio. "The Virgin ſuckling the Infant Jeſus," from L. Caracci, in folio.

Michel Corneille, the eldeſt ſon of the former, was born at Paris in 1642, and died in the ſame city in 1708. He was educated by his father, and became one of the moſt celebrated members of the Royal Academy. In order to diſtinguiſh his works from thoſe of his father, he ſometimes added an A to his baptiſmal name, on which account he has received the appellation of Michel-Ange Corneille, though he is ſometimes called Corneille of the Gobelins. Having learned the rudiments of art from his father, he went to Italy to complete his ſtudies in the ſchool of the Caraccii, the ſtyle of whoſe deſign he occaſionally imitated with ſome ſucceſs. He underſtood perſpective, and the management of light and ſhade, better than the majority of contemporary French artiſts; and though he chiefly excelled in hiſtory, was not without a conſiderable ſhare of merit in landſcape. Strutt ſays of his four engravings from the life of the patriarch Abraham, which are after his own deſigns, that "they are etched in a fine, bold, free ſtyle; the compoſitions are full of grandeur; the heads are peculiarly characteriſtic; the extremities, like thoſe of Raphael, are finely drawn, and the draperies diſpoſed with great taſte. One may ſee how cloſely he has ſtudied the celebrated Italian painters, and admire the good uſe he has made of thoſe ſtudies. The figure of Abraham in the laſt, has much of the ſtyle of Polidoro Caravaggio in it, and all the naked figures in the third are drawn in the manner of Caracci."

A printſeller of Rome having obtained theſe four plates, and having heard of the fame of Raphael, had the crafty ignorance to inſcribe beneath them the name of that great painter, and there were perſons at that time, as at preſent, the ready dupes of deception, and who conſulted no other oracles for the truths of art.

The ſubjects of theſe four prints, which are now become very ſcarce, are, 1ſt. The Deity appearing to Abraham. 2d. Abraham journeying with Lot. 3d. Abraham putting to flight the Army of the Confederate Kings. 4th. Iſaac taking leave of his mother before his departure for the ſacrifice. The remainder of the principal works of this artiſt are as follow:

"Delilah cutting off Sampſon's Hair." "The miraculous Conception." In this piece St. Ann and St. Joachim are repreſented in attitudes of admiration, and above is ſeen the Holy Ghoſt. "The Annunciation," occupying two plates. The angel is engraved on one, and the Virgin Mary on the other. Another "Annunciation" on a ſingle plate. "The Nativity, with the Shepherds worſhipping Chriſt." The infant Jeſus is lying in the manger amid oxen and aſſes. "The Flight," from a picture in the White Penitents, at Lyons, in which St. Mary is repreſented as about to enter a boat. "The calling of Peter and Andrew," a picture in Notre Dame, at Paris. "The Virgin embracing the Infant Jeſus, worſhipped by St. John the Baptiſt," from a painting in the Feuillans, at Paris. "St. John the Baptiſt in the Deſert." "Jeſus Chriſt, the Way, the Truth, and the Life." "St. Andrew adoring the Croſs," finiſhed by Jean Mariette. This is a beautiful ſmall upright, from a deſign by Corneille himſelf. "Jeſus Chriſt and the Virgin appearing to St. Francis," from a painting in the Capuchins, at Paris. "St. Francis of Aſſiſe," at full length. "St. Francis liſtening to celeſtial Muſic." "St. Anthony of Padua carrying the Infant Jeſus in his Arms." "The Apotheoſis of Æneas." "Hercules ſupporting the Globe of France." "The Genius of Painting." This is a frontiſpiece to M. de Piles' Lectures on Painting. "The Inhabitants of Madagaſcar ſwearing Fealty to the King of France." "The betrothing of St. Catherine," from a deſign of L. Caracci, in folio. "The Virgin," from Caracci, in folio. This is a landſcape in which the Virgin is repreſented ſitting at the foot of a rock, with the infant Jeſus. "A Landſcape," in which Jacob is ſeen ſtruggling with the Angel, after Ann. Caracci. "St. John the Baptiſt preaching in the Deſert," from the ſame. "St. John the Baptiſt interrogated by Two Diſciplies," a landſcape from the ſame. "St. Francis diſgraced," a landſcape from the ſame. "Mercury preſenting the Lyre to Apollo," a landſcape from the ſame. "Silenus, a Satyr, and a Faun," a landſcape from the ſame. "Pan ſeated with Apollo," a land-

landſcape from the ſame. "An indigent Family, followed by a lame Beggar on Crutches," from the ſame. "Hagar baniſhed by Abraham," after P. da Cortona, falſely aſcribed to Ann. Caracci, in folio.

Beſides the above, he etched from the works of his father, "The Sacrifice of Abraham," "King Phineas delivered from Harpies," and "Cleopatra taking the Aſp from the Baſket of Fruit."

Jean Baptiſte Corneille was born at Paris in the year 1646, and died in the ſame city in 1695. Strutt has dated his birth ten years earlier, and has ſpoken of him as the elder brother of Michael, when he was really the younger. Without uniformly evincing the ſame excellence as his brother, he is ranked among the celebrated artiſts of the French ſchool. After reſiding ſome time at Rome, he returned to Paris, and was ſoon after nominated a profeſſor of the French academy. He painted, at Notre Dame, "St. Peter delivered from Priſon;" and for the church of the Carmelites, "The Appearance of our Saviour to St. Thereſa and St. John, after his Crucifixion."

Like his brother, he etched ſeveral pieces of his own compoſition, as well as from thoſe of the Caraccii.

It is to Jean Baptiſte Corneille that we owe the publication of the fineſt ſtatues of Florence and Rome, reduced from actual meaſurement, of which himſelf engraved the greater number; the others were executed by F. Mariette, and C. Simoneau.

Among the pieces engraven by himſelf, may be mentioned "The Buſt of Michael Angelo." "Suſanna ſurpriſed in the Bath." "St. Auguſtin, ſeated in a Garden, in the Midſt of his Diſciples." "A half length Figure of St. Bernard." "Jeſus Chriſt appearing to St. Thereſa and St. John, after the Crucifixion," from his own painting in the Carmelite church at Paris. "The Buſt of Monſieur, crowned by Victory, with the Trophies taken at the Battle of Caſſel." "A Medallion of Apollo contemning Love." "A Medallion of Daphne transformed into a Laurel." "Virtue preparing her Crowns," an octagon. "An oval Medallion of Apollo playing at Quoits with Hyacinthus." "The Moon mounted on her Chariot drawn by Stags," finiſhed by J. Mariette. "Mercury in an Orb," finiſhed by the ſame. "Diana diſcovering the Intrigues of Caliſto." A collection of fifty plates of deſigns for the uſe of architects. The plates for the elements of painting, by M. de Piles. "St. John the Baptiſt in the Deſert," a landſcape from Annibal Caracci. "The Samaritans," a landſcape from the ſame. "St. Francis branded with Diſgrace," from the ſame.

Several artiſts have engraven from the originals of Jean Baptiſte. J. Mariette alone has himſelf engraven and cauſed to be executed fifty-five of his pieces.

Henry Mauperche was born at Paris A. D. 1606, and died in the ſame city in 1686. We are not informed whether he ever viſited Italy, though this ſeems highly probable, for his ſtyle of painting and engraving greatly reſembles that of Herman Swanevelt; after whom he has engraven ſeveral landſcapes.

He became a member of the royal academy, and though a landſcape painter, was nominated profeſſor in 1655. Fourteen hiſtorical landſcapes were painted by him on the walls of one of the royal apartments at Fontainebleau. He has alſo engraven ſeveral landſcapes, the greateſt number of which are of his own compoſition, of which the following claim reſpectful attention. A ſeries of ſix plates from the ſtory of Tobias, in folio. A ſeries of ſix plates illuſtrative of the life of the Virgin Mary, from the Annunciation to the flight into Egypt, in folio. A ſeries of twelve landſcapes from Swanevelt, in 4to. Two ſubjects from the Bible; 1ſt. "The Prodigal Son ruined by Courteſans." 2d. "The Prodigal Son received by his Father," inſcribed "H. Mauperché inv. pinx. et fec." in folio. Two landſcapes, with ruins and figures, id. fec. in folio. Two mountainous landſcapes, with buildings and figures, id. fec. in folio. A landſcape from the fable of Marſyas, id. fec. in folio.

Laurent de la Hire was born at Paris in 1606, and died in the ſame city in 1666. His father Stephen de la Hire, who had long exerciſed the profeſſion of a painter in Poland, obſerving the promiſing talents of his ſon, inſtructed him in the principles of his art. Young de la Hire afterwards ſtudied in the ſchool of Vouet, and was the firſt pupil of that maſter who ſtruck out for himſelf a new path. Notwithſtanding ſome imperfections, his paintings acquired him great reputation, and he was received into the academy in 1648.

But it is rather as an engraver, than as a painter, that we ought to regard de la Hire. He has engraven, in a light and elegant ſtyle, ſeveral pieces after his own compoſition. "A Holy Family, in which St. John is ſeen kiſſing the Feet of the Infant Jeſus." This piece is inſcribed L. de la Hire inv. et ſc. in folio. Another "Holy Family." This is a very fine landſcape, into which a great number of angels are introduced, id. fec. folio. "A landſcape." In this piece the Virgin Mary is ſeated on the ground, behind her St. Joſeph, and before her the Infant Jeſus, who bruiſes a ſerpent with a croſs brought by angels, id. fec. 1639 in folio, "A Repoſe during the Flight to Egypt;" a beautiful landſcape in folio, id. fec. "Chriſt with the Holy Women, and St. John, at the Foot of the Croſs;" inſcribed L. de la Hire, 1639. aq. fort. in folio. "The Converſion of St. Paul," id. fec. in folio. This piece is deſervedly admired. "The Judgment of Paris," in a beautiful landſcape, id. fec. in folio.

Iſrael Henriet was born at Nancy in the year 1607, and died at Paris in 1661. He was the ſon of Claude Henriet, a painter from Châlons, who had ſettled at Nancy. He went to Rome with the view of improving himſelf in the art of painting, under the direction of Antoine Tempeſta; but it ſhould ſeem that his progreſs was not conſiderable. On his return to his native country he ſettled as a printſeller at Paris, and Callot, de la Bella, and eſpecially Iſrael Silveſtre, his nephew and pupil, were employed by him. His ſtyle of engraving is ſimilar to that of Callot, with whom he was connected in the ſtricteſt bonds of friendſhip. At his death, Silveſtre inherited all his plates, which were extremely numerous. Iſrael Henriet has left behind him a vaſt variety of views and ſmall pieces from his own hand.

Remi Vuibert, or Wiburt, who was educated by Vouet, is ſuppoſed to have been a native of Paris, and to have been born about 1607. He reſided chiefly at Rome, where he executed ſeveral etchings from Raphael, Guido, Dominichino, and other Italian maſters, as well as from his own deſigns, among which the following are moſt remarkable. "The Cure of one poſſeſſed by the Devil," from a deſign of his own, dated 1639, in folio, nearly ſquare. A ſeries of arabeſque and groteſque figures, painted by Raphael for the Vatican, 13 pieces in folio; the ſame figures which were ſubſequently engraven by G. Audran. "Adam and Eve eating the forbidden Fruit," from a picture in the Vatican, by Raphael, 1635, 4to. "The Deciſion of Solomon," from the ſame, 1635, ſmall folio. "Marſyas conquered by Apollo," from the ſame, in 4to. "Providence governing the World," from the ſame, 4to. "The Deſcent from the Croſs," after Pouſſin, in folio; this piece has likewiſe been engraven by Stephen Gantrel.

Nicolas

Nicolas Mignard was born at Troyes, in Champagne, in the year 1608, and died at Paris in 1668. He acquired the udiments of art under Jean Boucher, of Bourges, and carefully ſtudied the antique ſtatues and pictures of Primaticcio and of M. Roux, preſerved in the palace of Fontainebleau. He afterwards took a journey to Italy, and, on his way thither, ſtopped at Avignon, where he became a huſband. During the period he remained with his father-in-law, he received the appellation of Mignard of Avignon. From this city, he departed for Rome, in order to improve himſelf in art. He painted ſeveral hiſtorical ſubjects for the palace of the Thuilleries; ſome portraits, by which he acquired great reputation; and he engraved the following eight plates from the pictures of Annibal and Agoſtino Caracci in one of the apartments of the Farneſe palace. 1ſt. "The Choice of Hercules." 2d. "Hercules repoſing after his Labours." 3d. "Hercules ſupporting the Globe." 4th. "Ulyſſes braving the Song of the Syrens." 5th. "Amphinome and Anape." 6th. "Perſeus ſtriking off the Head of Meduſa." 7th. "The Rape of Ganymede." 8th. "The Triumph of Bacchus."

Michel Dorigny was born at St. Quentin in 1617, and died at Paris in 1665, the diſciple and brother-in-law of Vouet, he conſtantly imitated the ſtyle of his maſter. Some pictures were executed by him for the chateau of Vincennes. Dorigny engraved more than a hundred pieces from deſigns by his father-in-law, in which he has faithfully preſerved the character of the originals. His execution is bold and deciſive; he well knew how to economiſe his light, and to impart to his draperies an eaſy and natural caſt. But he was not equally ſucceſsful in drawing, eſpecially of the hands and feet of his different perſonages. He executed, from his own invention, a ſeries of ſix plates, repreſenting the feſtivals of fauns, ſatyrs, bacchantes, &c. in folio; and from Vouet he etched the following:

"The Nativity of our Saviour," in folio. "Apollo aſſuming the Guidance of the Chariot of the Sun," in folio. "Apollo killing with his Arrows the Serpent Python," in folio. "Peace deſcending on Earth," in folio. A landſcape, in which the Holy Family is introduced, a ſmall folio, dated 1649. "The Harpies driven from the Palace of Phineas by the Children of Boreas," in folio. "Venus at her Toilet," ſmall folio. "Venus and Hope plucking the Wings of Love," ſmall folio. "Mercury and the Graces," from the ſame. "The Rape of Europa." "Iris tearing the fatal Hair from Dido on the funeral Pile," in folio. "The Kings of Arabia and Saba, with their Attendants bringing preſents to the Infant Jeſus." This ſubject was executed for the cieling of the hotel de Fermes, and is engraved in the manner of a frieze, on four plates.

Nicholas Robert was born, according to ſome accounts, at Langres, and from others at Orleans, in 1610, and died at Paris in 1684. Beſides his productions as a painter, Robert engraved the moſt rare flowers, birds, and the animals of the royal menagerie. He alſo etched, in conjunction with Gerard Audran, ſix cielings, and ſix plates of vaſes from George Charmeton.

Gregoire Huret was born at Lyons in the year 1610, and died at Paris in 1670. His engravings are numerous, and many of them from his own deſigns. "His compoſitions are neither learned nor judicious, and his drawing by no means correct. He worked with the graver only, in a coarſe, heavy ſtyle, apparently a diſtant imitation of that of Poilly." Such is the account which Strutt gives of this artiſt; Watelet ſpeaks much more favourably, but our countryman will probably be found nearer the truth.

We begin our liſt of his principal works, with the portraits which he has engraven, and which are of the folio ſize.

Jaques Bouceau equerry, lord of Baranderée, from A. de Vries. Francis de Bonne, duke of Leſdiguerres, conſtable of France, from Dumouſtier. This piece has a border with emblematical figures. Pierre Seguier, chancellor of France, in an ornamented frame, ſigned Greg. Huret fecit. An allegorical portrait of the author of the work entitled "De la Souveraineté de Roy." A ſeries of thirty-two plates illuſtrative of the paſſion of love. The liſts of his hiſtorical and allegorical engravings, which are alſo of the folio ſize, are,

"The Condemnation of St. Stephen." "St. Peter preaching to the Chriſtians, who receive the holy Spirit." "A Holy Family, with St. Catherine and another Saint." "The miraculous Image of our Lady of Lieſſe," inſcribed to the ducheſs de Nemours, 1655, a large folio. "Chriſt with the Crown of Thorns." "Louis XIII. and Queen Anne preſenting the Dauphin to the holy Virgin," dated 1638. "Wiſdom, Peace, and Eloquence ſupporting the Arms of Richelieu," 1638. "Frontiſpiece to the Hiſtory of the civil Wars of France."

The date of the birth and that of the death of Jaques Bellange have not been recorded. Strutt ſays that he flouriſhed towards the cloſe of the laſt century, and Huber that he was born ſome time about 1610, but both agree that he was a native of Chalons. He learned the rudiments of drawing under Claude Henriet, and afterwards ſtudied at Paris in the ſchool of Vouet. Baſan ſays of him that "he was a bad painter and a worſe engraver," and that, "in his etchings, which are from his own compoſitions, we find much fire, more caprice than judgment, little correctneſs, and very bad taſte;" but Mr. Strutt thinks this ſentence too harſh, and, commenting on Bellange's plate of the Virgin Mary and infant Chriſt, ſays that the ſtyle of engraving in which it is executed, "however ſingular, is by no means deſtitute of merit: his drawing appears to me to be incorrect rather from affectation than want of knowledge; the whole figure of the child is well executed; there is indeed an awkwardneſs in the turn of the figure of the Virgin, and the character of her head is childiſh." His etchings in general are ſlight, but free, and often maſterly; and he ſometimes, in the nudities of his figures, introduced ſtippling with the graver, by way of harmonizing and ſoftening the roughneſs of his etching.

Bellange left behind him fifty engraved plates, of which the principal, of a folio ſize, are as follows:

"The Holy Family, with St. John and St Catherine," a large upright. "The Annunciation," of a ſquare form. "The Reſurrection of Lazarus," an upright. "The Adoration of the Magi." A ſet of three ſingle figures of Eaſtern Kings, *viz.* Caſpar of Tarſus, Melchior of Nubia, and Balthaſar of Sheba. "Chriſt bearing the Croſs," large. "A dead Chriſt, ſupported on the Knees of the Virgin," ſmall folio. "The Three Marys viſiting the Sepulchre." "St John the Baptiſt in the Deſert." "The Martyrdom of St. Lucia." "The Death of Virginia." "Adonis bearing Diana on his Shoulders." "A back View of a Warrior ſtanding, and a Female leaning on a Drum, with a City in the diſtance." A ſeries of five female figures ſtanding in different attitudes. A ſmall oval of "St. Mary Magdalen, with her Hand on her Boſom."

Pierre Daret was born at Paris in the year 1610: after acquiring the rudimental principles of engraving in France, he went to Italy to complete his ſtudies, and remained there a conſiderable time; but finally returned to his native city, and

and died there at a very advanced period of life. He was not only a deſigner and engraver, but had ſome pretenſions to literature. Florent le Comte informs us that he compoſed a life of Raphael, which was printed in the year 1656, but it is little more than a free tranſlation of that from the pen of Vaſari. A portrait of Raphael is prefixed to the volume.

Strutt's ſummary of the talents of this artiſt is as follows: "his works are chiefly performed with the graver, without any other aſſiſtance. The mechanical part of his engraving is cold and ſilvery, the effect flat and unharmonized, and the drawing of the naked parts of his figures is frequently incorrect and heavy, more eſpecially the extremities. His works are in number very conſiderable, amounting to upward of two hundred and ninety-ſix prints." According to Huber they are much more numerous; and many of them are marked with his cypher, for which the reader is referred to our plate of the monograms, &c. of the French ſchool of engravers.

The following are ſome of the hiſtorical pieces executed by Daret from different maſters, and are all of the folio ſize.

"St. John ſeated in the Deſert, with a Lamb on his Knees," from Guido. "The Madonna ſuckling the Infant Jeſus," from Annibal Caracci. "St Peter delivered from Priſon," after Dominichino, a large upright. "Jeſus laid in the Sepulchre," from Baroccio. This piece appears under the name of P. Mariette. "A Holy Family, in which is introduced an Angel preſenting Fruit to the Infant Jeſus," from S. Vouet. "A dead Chriſt mourned over by holy Women," from the ſame. "St. Jerome ſeated in the Deſert, writing," from Blanchart, a half-length figure. "Thetis requeſting Arms for Achilles," from the ſame. "Charity, with Five Infants," from the ſame. "The Viſitation, or meeting of the Virgin Mary and St. Elizabeth," from M. Corneille the father. "The Virgin ſeated with the Infant Jeſus," from the group of Jac Sarazin. Upwards of a hundred ſmall plates for a work entitled "La Doctrine des Mœurs," publiſhed by M. Le Roy, of Gomberville, in 1646, from the deſigns of Otho Vænius.

Among the portraits of P. Daret, we find, of the quarto ſize, a buſt of Alexander the Great, with illuſtrations from Plutarch. Pope Alexander VIII. Charles I., king of Great Britain. Henry of Bourbon, prince of Condé, firſt prince of the blood. Charlotte Marguerite de Montmorency, princeſs of Condé. Donna Olympia Maldalchini. Bernard de Saxe, duke of Weimar. Henry de la Tour d'Auvergne, viſcount de Turenne.

And in folio, queen Anne, with the two princes on the throne, for the Hiſtory of Mezeray. Marguerite Gaſton, ducheſs of Orleans, 1652. Louis le Fevre de Caumartin, chancellor of France. Ladiſlaus IV., king of Poland, engraven in 1645.

Louis Boullongne, the father, was a native of Picardy, and born in 1610. After paſſing ſome years in Italy, he returned to France, and ſettled in Paris, where he died in the year 1674, having for ſome time enjoyed the reputation of being an excellent artiſt, and the honour of being profeſſor to the French Academy.

He engraved from his own pictures the Miracle of St. Paul at Epheſus, and the Decollation of that Apoſtle at Rome. He alſo, during his reſidence at Rome, executed a plate from Guido of the Rape of Helen.

Boullongne left behind him two ſons, of whom Bon, who was born at Paris in the year 1649, and died in that city in 1717, was the elder. While under the tuition of his father, he diſplayed conſiderable talent, he however paſſed five years at Rome, after which he proceeded to Lombardy, where he ſtudied the works of Correggio, and the Caraccii. An able deſigner, and good colouriſt, his manner partook of the perfections of both theſe great maſters; he likewiſe excelled in compoſition; and all his productions, but particularly his Reſurrection of Lazarus, are ſtamped with a grand character.

Bon Boullongne engraved ſeveral pieces of his own compoſition, among which are, "a Holy Family," in folio. "St. John preaching in the Deſert," a large upright. "St. Bruno ſeated in a Landſcape," and its companion, both in folio. The frontiſpiece to an almanack, engraven in 1694; and, a ſatire againſt the author of Mercure-galant, who amuſed himſelf at the expence of painters: beneath are the following words: "Ah ha, galant vous raiſonnez en ignorant."

Louis Boullongne, the younger brother of Bon, was born at Paris A.D. 1654, and died in the ſame city in 1734. Having received the ſame inſtruction as his brother, he ſet out for Italy. During his ſtay in Rome he copied ſeveral of Raphael's pictures; and it was from his copies that thoſe celebrated works were executed in the tapeſtries of the Gobelins. On his return from Italy he was admitted into the Royal Academy, in conſequence of his pictures of "Auguſtus ſhutting the Temple of Janus," the "Flight into Eygpt," painted for the church of Notre Dame, and the "Preſentation in the Temple." After the death of Ant. Coypel he was nominated firſt painter to the king, and chevalier of the order of St. Michael.

He etched the following plates, which, though ſpirited and free, are not correctly drawn. "A Holy Family," in 4to. in which the infant Jeſus is holding a bird in his hand. Another "Holy Family." "A dead Chriſt, ſurrounded by Saints, Women, and his Diſciples," in folio. "The Martyrdom of St. Peter," an upright, in folio. "The Martyrdom of St. Paul," in folio, its companion. "The Flagellation of St. Andrew," from Paul Veroneſe, in folio. "St. Bruno," in folio. "A Roman Charity," in folio.

Abraham Boſſe was born at Tours A.D. 1610, and died at Paris in 1678. Beſide his engravings, which amount (according to Huber) to eight hundred in number, and the greater part of which are from his own deſigns, he is the author of certain eſſays on perſpective and architecture, which have been printed; and he has the honour of being the firſt Frenchman who produced a treatiſe on the art of engraving; a work of which M. Cochin has given a new and improved edition, and of which there is an Engliſh tranſlation.

Under what maſter he ſtudied, his biographers have not mentioned. In the ſtyle of his engraving, he was the evident imitator of the coarſer manner of Callot, and for the moſt part employed the hard varniſh, (for which ſee the article ETCHING,) which that artiſt invented. The execution of his plates is accordingly clear and pleaſing, poſſeſſing much of that peculiar brilliancy of line which the graver produces; yet his lights are in general too much ſcattered.

Boſſe drew with a certain degree of ſpirit, but rather with ſpirit than with truth, and finiſhed his etchings by partially re-entering the corroded lines with the graver: but his practice, as well as his theory, was fettered by a ſuperſtitious preference, which appears to have originated in Germany, for the clear and clean cut lines which the latter inſtrument produces. Hence he imitated, whilſt etching, the work of the graver, and hence, in his treatiſe, he erroneouſly taught others to eſtimate the value of etching, by its degree

of reſemblance to the lines produced by the graving tool; a very falſe criterion of merit, and upon which Watelet juſtly remarks, that it is better to impart to each ſpecies of engraving the character peculiar to it; to leave to etching its freedom and playfulneſs, and to the graver its wiſdom and ſeverity.

Boſſe was a member of the Royal Academy of Paris, but the independence of his character led him to reſiſt the real or imaginary deſpotiſm of Le Brun, who at that time (ſays Huber) reigned over the arts with imperious ſway, and he was expelled in conſequence. Of his numerous engravings, the following will probably be found moſt worthy of notice:

Portraits of the queen dowager ſitting, with the young king of France and his brother ſtanding by, in folio, and without the ſignature of the artiſt. The portraits of cardinal Richelieu, and of Callot the engraver, with his epitaph, are alſo of the folio ſize. The king and queen of France addreſſing their prayers to the holy Virgin, of the proportions of a frieze. "Judith with the Head of Holofernes." "A Figure wrapt in a Mantle, leaning againſt a Tree," engraved by Boſſe and Mellan. "The preparation of a Chriſtian Soldier for ſpiritual Warfare." "The French Army." "The Siege of la Motte." "The Reduction of Mantua." All of the folio ſize. "The Adoration of the eaſtern Kings," in 12mo. "The Virgin ſitting, with the infant Jeſus on a Pedeſtal, behind her St. Joſeph," 12mo. "The Hiſtory of Dives and Lazarus," ſix pieces in folio. "The Hiſtory of the Prodigal Son," in folio. "The Parable of the wiſe and fooliſh Virgins," ſeven pieces in folio. "The ſeven Works of Miſericordia," in folio. "The Miraculous Image of St. Anne," folio. "The magnificent Proceſſion of the Hunt of St. Genevieve," folio. "Ceremony obſerved at the contract of marriage between Ladiſlaus IV. king of Poland, and Maria de Gonzague, which took place at Fontainbleau in 1645," folio. "Marriage ceremony of Louis XIV.," folio. "The hall of Charity," folio. "The Gallery du Palais Marchand," folio. The painter, ſculptor, engraver, and printer, engaged in their reſpective employments, a ſet of four plates, folio. A ſchool-maſter and ſchool-miſtreſs, two plates, folio. The four elements in the coſtume of the times, demi-figures, four ſmall pieces in 4to. The four quarters of the globe, in medallions, four plates in 4to. The four ſeaſons, repreſented by ſubjects of converſation, a ſet of four plates, in folio. The five ſenſes, repreſented in the ſame manner, on five folio plates.

Boſſe alſo engraved a few plates from Bourdon, Bellange, Deleſtain, Paul Farinati and others, and has been cenſured for devoting (either from choice or neceſſity) a portion of his time to trifling and temporary ſubjects, ſuch as fans, and affairs of French gallantry, which we forbear to enumerate.

Claude Dervet was born at Nancy in the year 1611, and died in 1642. He was the pupil of Iſrael Henriet, and the friend and fellow-citizen of Callot, whoſe ſtyle of engraving he ſucceſsfully imitated.

Of all his engravings, the two following are only known to us; they are both of the folio ſize.

Charles IV., duke of Lorraine on horſeback, ſurrounded with military inſignia, with the following inſcription on a cannon, C. Dervet fec. 1628. This piece was engraven for a book entitled "Triumpho de S.A. Charles III. Duc de Lorraine à ſon Retour dans ſes Etats," Nancy, 1604. The invention of this piece is attributed to Callot, and the little view, which accompanies the portrait, of the city of Nancy, is engraven by F. Clere. "A Pallas on horſeback, holding, in her right Hand, a Club." The invention of this piece has alſo been attributed to Callot.

Pierre Lombart was born at Paris in the year 1612, and is ſuppoſed to have frequented the then popular ſchool of Vouet; but it is not known where, or under whoſe inſtruction, he acquired the rudiments of the art of engraving. After exerciſing his profeſſion for ſome time in Paris, he repaired to London, and the reader will find his principal works, and the ſtyle of his engraving ſpoken of in our account of the origin and progreſs of Engliſh engraving; and his cypher, or mark, among thoſe of the French ſchool of engravers.

Of ſuch of his works as were executed in France (in addition to thoſe which we have already mentioned) we are enabled to ſupply the following liſt:

"St. Michael's Victory over Satan, or the Commencement of the Millennium," after Raphael, from the celebrated picture which was formerly at Verſailles. "The Virgin and Child ſeated on a Throne," from Annibal Caracci. "The Adoration of the Shepherds," from Pouſſin. An "Holy Family," in which the infant Jeſus is careſſing St. Joſeph; all which are of the folio ſize.—The following portraits are alſo from the graver of Lombart. The painter Walker, from a picture by himſelf, in folio, an oval. Sir Samuel Moreland, after ſir Peter Lely, in 4to. an oval. Anne Hyde, ducheſs of York, from the ſame painter, in 8vo, an oval. Jeremy Taylor, with a Latin inſcription, folio. Thomas Morant, marquis du Meſnil, maſter of requeſts, folio, an oval. Gabriel Chaſſebras, de la grand maiſon, maſter of the mint, folio. Jean Dallaens, miniſter of the goſpel, from W. Vaillant, folio. Anthony, duke de Grammont, from the ſame, folio. Pierre de Maſſart, counſellor to the king, from Cl. le Febure, folio. Chriſtianus Ludovicus, Dei gratia, dux Megapolitanus, princeps Vandalorum; inſcribed Richart de la Mane pinx. P. Lombart ſc. Pariſiis, 1670, folio. Vincentius Nevelet, in ſuprema regia curia ſenator, folio. William Daviſon, firſt phyſician to the king of Poland, after Schulz, folio. Brianus Waltonus, S.T.D. Cantab. coll. folio. This is a ſcarce print, but the following is among the ſcarceſt and beſt of the engravings of Lombart, *viz.* "In effigiem Domini de la Fond," a print perhaps better known under the title of "Gazzetier a Hollande," after H. Gaſcard.

Jean Morin was born at Paris in the year 1612, or thereabout, and died in the ſame city in 1666. According to Strutt's account of him, "he was a man of great ability; he ſtudied painting under Philip Champagne, but relinquiſhed that art in order to follow engraving. His plates are executed in a ſingular ſtyle; a mixture of lines and dots, harmonized with each other ſo as to produce a very agreeable effect. They are chiefly etchings; for he does not appear to have underſtood the management of the graver, by any means equal to that of the point. His portraits, which form the more numerous part of his works, are many of them executed in a maſterly manner, and though not finiſhed with all the preciſion and delicacy which the graver is capable of producing, manifeſt at leaſt the good taſte, freedom of hand, and knowledge, of the artiſt." Among the more eſtimable of his works, are the following:

"Head of St. Vincent, in the chapel of St. Germain of Auxerre." This is really the portrait of Morin himſelf painted by his friend Champagne. From the ſame painter he has engraved, of the folio ſize, "The Adoration of the Shepherds." "The Virgin Mary careſſing the infant Jeſus." "The grand Crucifix," a capital piece engraved

on three plates. "Jeſus Chriſt dead on the Croſs." "The Virgin carried up to Heaven by Angels," from a ceiling. Two plates, companions, of which the ſubjects are, "St. Peter, and St. Paul," half-lengths. Another pair, of "St. Jerome and St. Bernard." Two pieces, repreſenting "Groups of Angels in the Air," in quarto. A frontiſpiece to the pſalms of David, in 8vo. "The Virgin holding a Bunch of Flowers, with the Infant Jeſus on her Knees, who is placing a Roſe in the Boſom of his Mother," Raphael pinx. with the motto "Dilectus meus mihi," folio. "The Virgin adoring the infant Jeſus ſleeping on Straw," from Titian, folio; a beautiful ſpecimen of the engraver's ability. "The Virgin contemplating the Body of Jeſus extended on the Earth," from Caracci. "A Landſcape with Ruins, under which Goats are ſeen browſing," from Claude Lorrain, in 4to. In this, as in moſt of the following, Morin has attempted to finiſh the diſtances with dots, but with no great ſucceſs. A landſcape with a ruſtic houſe, and in the fore ground a man driving cows, from Fouquier, in folio. A mountainous landſcape, in the fore ground is ſeen a traveller on horſeback, preceded by a man on foot, from the ſame; large folio. Four landſcapes, with ruins and figures, from Corn. Polenbourg, in folio. A landſcape, on one ſide of which is an antique fountain, and on the other ruins, from L. B. Corneille, in folio.

The following twenty-four of the moſt beautiful portraits of Morin, are from Champagne, and are of the folio ſize. Louis XIII. king of France, an octagon. Anne of Auſtria, Regent, bare-headed. Anne of Auſtria, in weeds, and a black mob-cap. Jean Baptiſte Amador, abbe of Richelieu. Armand, cardinal de Richelieu, an octagon. Jules, cardinal de Mazarin. Corneille Janſenius, biſhop of Ypres. Jean Paul de Gondy, archbiſhop, and afterwards cardinal of Rez. Pierre Bertier, without letters, his hair curled, ſmall muſtachios, and the biſhop's croſs. Francis de Sales, biſhop of Geneva, without the painter's name, an octagon. S. Charles Borromee, cardinal and archbiſhop of Milan, an oval. Jean Pierre le Camus, biſhop of Bellay, an octagon. Jean du Verger of Haurane, abbe of Saint Sarin. Michael de Morillac, keeper of the ſeals. Michael Tellier, ſecretary of ſtate. Jaques Tubœuf, preſident of the chamber of accounts. Rene de Longuevil, ſeigneur de maiſon, preſident a mortier. Henri de Lorraine, count d'Harcourt. Nicolas de Neuiville, marquis of Villeroy. Charles de Valois, duc d'Angouleme. Robert Arnauld, lord of Audilly. Vincent Voiture, of the French academy. Jaques le Mercier, firſt architect to the king. Antoine Vitré, a celebrated printer at Paris, an octagon.

The following portraits by Morin, are from various other maſters:

Jaques-Auguſte de Thou, preſident of the parliament; Ferdinand pinx. in folio. Francis Auguſtin de Thou, preſident of the Parliament; Ib. pinx. in folio. Guido, cardinal de Bentivoglio; A. Van Dyke pinx. in folio. An anonymous portrait of a lady. Ib. pinx. in folio. This is the portrait of the counteſs de Boſſu. An anonymous portrait of a man with a ſhort beard, and the head bare. Ib. pinx. This is the portrait of Charles de Mallery, engraver and print-ſeller at Antwerp. Dom Gregoire Tarriſſe, ſuperintendant general of the congregation of St. Maur. Dunſtan pinx. Hieronyme Franeque, painter to the king. Se ipſe pinx. an octagon, in folio.

Jean Boulanger, was born at Troyes about 1613, and died at an advanced age, in Paris, where he publiſhed a great number of prints, both of his own compoſition, and from other maſters.

Boulanger is preſumed by Strutt to have formed his firſt manner of engraving on that of Francis de Poilly; he was the contemporary of Morin, and like him endeavoured to impart a ſoftneſs and mellowneſs to his fleſh by dotting or ſtippling. But Morin produced his dots by aqua-fortis, while Boulanger employed the graver; and as the draperies and back grounds of his prints are engraved in lines, with little or no intermixture of ſtippling, an effect of more or leſs of diſſonance is generally produced, and the back grounds of his portraits and his Madonnas are more eſpecially coarſe and harſh; but notwithſtanding this defect, and that he did not draw the naked parts of his figures either with correctneſs or fine taſte, the peculiarity of his manual execution, and the care which he has manifeſted, have obtained him many admirers. In ſubſcribing his name to his engravings, he has frequently joined the J of his baptiſmal name to a ſmall b, in ſuch a manner as greatly to reſemble an H, and hence it is ſometimes erroneouſly read Houlanger, and has ſometimes been ſo inſerted in printſellers' catalogues.

Of the following ſubjects, thoſe which are mentioned firſt are of his own invention.

Two buſts, the one of our Saviour, the other of the holy Virgin, with her eyes caſt down, in folio. An oval buſt of the Virgin, with a border of laurel leaves, in folio. "The Virgin, with the Infant Jeſus," a half-length figure, in folio. Another of "The Virgin with the Infant Jeſus on her Knees, who is taking a Croſs from the Hands of St. John," and alſo a half-length figure, without a name, in folio. "The Virgin ſitting with the Infant Jeſus on her Knees, preſenting Pinks to him," a print known under the name of "La Vierge à l'oeillet," from Raphael, folio. A buſt of the Virgin with her eyes caſt down, having the following inſcription: "Mater amabilis," from the ſame; in folio, in a circle. "The Virgin holding the Infant Jeſus, to whom St. Joſeph is giving ſome Cherries," from Caracci, large folio. "The Virgin of Paſſau," from Salario, folio. "The Virgin ſitting with the Infant Jeſus aſleep in her Arms," from Guido, in folio. "The Virgin, with the Infant Jeſus and the little St. John who kiſſes her Feet," from the ſame, formerly in the cabinet of the French king, folio. This print has a very ſtriking effect. "Holy Family," from Noel Coypel, the father, folio. "A Holy Family," here the Virgin is repreſented kiſſing the Infant Jeſus," half-length figures, without the name of the painter, which is Nic. Loir, in 4to. "An Infant Chriſt," inſcribed "Salvator Mundi, miſerere nobis," from the ſame, 1651, in 4to. "Chriſt bearing his Croſs," by Nic. Mignard, in folio, large. "A Virgin holding the Infant Jeſus ſtanding, St. John embracing his Knees," from P. Mignard, in 4to. "The Deſcent from the Croſs," from a painting in the church of St. Benedict, painted by S. Bourdon, a large folio. "Jeſus Chriſt carried to the Sepulchre," from the ſame maſter, a large folio. "A large Crucifix," with a back ground, from Ch. le Brun, a large folio. A piece of ſuperſtitious folly, entitled "The Interior of the Virgin, with the Holy Ghoſt next her Heart," from the ſame. Buſt in folio. "The venerable Père Michael le Nolle, to whom the Virgin preſents a Crown," from the ſame, in 4to. "St. Francis de Paule, Founder of the Minimes," from S. Vouet, in folio. "The Body of Jeſus Chriſt borne away by Joſeph of Arimathea," from a picture by Claude le Febure, a large folio. "The magnificent Proceſſion which took place at Paris on the day that Louis XIV. attained to his Majority," from F. Chauveau.

Boulanger alſo engraved a conſiderable number of portraits, among which is that of Charles II. of England.

Simon Renard de St. André was born at Paris in the

year 1614, and died in the ſame city in 1677. He was educated a painter, and ſtudied under Louis Bobrum, but the following etchings, which are held in ſome eſtimation by the collectors of French art, are from his hand. "An Infant Chriſt contemplating the Croſs, which he holds on his Knees." A ſet of forty-ſix folio plates from the paintings and ſculpture in the gallery of the Louvre, conſiſting chiefly of bloated allegory, and fulſome compliment to Louis XIV. after Le Brun. "The Crucifixion," alſo in large folio, and from the ſame painter. This appears without the name of André, but is known to be from his hand. F. de Poilly has engraven from the ſame original.

Giles, or Egidius Rouſſelet, was born at Paris A.D. 1614, and died in the ſame city in 1686. He appears to have ſtudied in the ſchool of De Poilly and from the works of Bloemart, for his ſtyle partakes occaſionally of the merits and peculiarities of both thoſe artiſts. Rouſſelet drew with tolerable correctneſs, and diſcriminated the textures of the various ſubſtances repreſented in his engravings with more ſucceſs than moſt of his predeceſſors.

More than three hundred and thirty of his prints have been enumerated, of which number the following will probably be found moſt worthy of the notice of the connoiſſeur.

"A Holy Family," from Raphael, dated 1650, in folio. In this piece is repreſented the Virgin ſitting before the Infant Saviour, while St. John is preſenting him with a bird. "A Holy Family," from a painting of Raphael, formerly in the poſſeſſion of the duke of Orleans, engraven in 1656, folio. Here St. Joſeph is kneeling and preſenting flowers to the Infant Jeſus, who is ſeated on the knees of his mother. Another "Holy Family," from a painting of Raphael, formerly in the poſſeſſion of the king of France, known under the name of "The Virgin of Fontainbleau, or the fair Gardener." In this piece the Virgin is ſeated, with the Infant Jeſus by her ſide, and the little St. John kneeling before him. "A Holy Family," from a painting of Raphael, formerly at Verſailles, and which Louis XIV. cauſed to be engraven by G. Edelinck, folio. "St. Michael overcoming the Devil," from a picture by the ſame maſter, formerly in the cabinet of the French king, a piece frequently engraven, folio. "The Virgin with the Infant Jeſus, to whom St. John is preſenting a Croſs," from Guido, a piece falſely marked with the name of Caracci, folio. "The Annunciation," from Guido, folio. "St. Francis in Meditation," from the ſame, folio. "David with the Head of Goliah," from the ſame, folio. A ſet of four plates of the "Labours of Hercules," from the ſame maſter, formerly in the cabinet of the French king, in folio; *viz.* 1. "Hercules ſlaying the Hydra of Lerna;" 2. "Hercules ſtruggling with Archelaus;" 3. "Hercules ſlaying the Centaur Neſſus, the Raviſher of Dejanira;" 4. "Hercules on the Funeral Pile." Theſe are very diſtinguiſhed prints, and of the upright form. "David playing on the Harp," from Dominichino, folio. "St. Catherine preſenting a Lily to the Infant Chriſt, lying on the Knees of his Mother," from P. de Cortona, folio. "Jeſus Chriſt carried to the Sepulchre," from a painting by Titian, in the cabinet of the French king, a large folio, finely executed. A ſet of four plates of the Evangeliſts, from pictures by Valentino, formerly in the cabinet of the French king, nearly ſquare. "The Virgin Mary," from Jacques Blanchard, in folio. "Eliazar preſenting a Bracelet to Rebecca," from a celebrated picture by Pouſſin, formerly in the cabinet of the French king, in folio. The "Holy Family," in which the Infant Jeſus is holding an apple, and ſitting above a fountain, from Bourdon, in folio, "St. John the Evangeliſt," from the ſame, in folio. A large "Crucifix," with a dark ſky, in which are ſeen two groups of little angels, and two heads of cherubims; in the back ground, the city of Jeruſalem, from le Brun. "The Body of Jeſus Chriſt placed before the Virgin at the Foot of the Croſs," from the ſame, both in large folio. "A Holy Family," from the ſame, in folio. Here the Infant Jeſus is repreſented as if expounding the ſacred ſcripture. "A Magdalen," inſcribed "Remittuntur ei peccata," from the ſame, a half-length figure in an oval, folio. "St. Bernard kneeling before the Virgin," from the ſame, in folio. "St. Thereſa in Contemplation," from the ſame, folio. "The Great Thèſe of count de St. Pol," in which Louis XIV. is ſeen on horſe-back, from the ſame.

Portraits.—Francis Hedelin, abbé of Aubignac. Egid. Rouſſelet ad vivum ſc. 1663, in 4to. Charles le Fevre, abbot of St. Geneviéve, inſcribed G. Rouſſelet del. et ſc. in folio. Francis Boulart, abbot of St. Geneviéve, in folio. Charles de Valois, duke of Angoulême, oval, in folio. Meſſire Pierre Seguier, chancellor of France, with ſupporters, from Le Brun, in folio. Richard de Belleval, chancellor of the univerſity, from the ſame, in folio. Frontiſpiece to the Polyglott bible, after Sebaſtian Bourdon, an engraving of conſiderable merit, wherein Fame is repreſented bearing the medallion of cardinal Mazarin, and Hiſtory preſenting the Holy Scriptures to France.

Samuel Bernard was born at Paris in the year 1615, and died there in 1687. He is ſaid to have been a pupil of Vouet, and to have painted in freſco and in miniature. As an engraver, his merit is inconſiderable: his drawing is incorrect, his draperies ſtiff and heavy, and his chiaro-ſcuro black and inharmonious: yet there is a certain degree of neatneſs in his execution. His plates conſiſt chiefly of etching, the lights being ſoftened by ſtippling with the graver.

Baſan has miſtakenly ſuppoſed that there were two artiſts of this name, from noticing two ſeveral admiſſions of Samuel Bernard to the French Academy; but the truth is, that our artiſt was originally admitted in the year 1655, was expelled on account of his adherence to the Proteſtant religion, (on the revocation of the edict of Nantes, in 1681,) and was afterwards re-admitted to a profeſſorſhip, on recanting his faith and becoming a member of the Catholic church. His moſt eſteemed engravings are as follow, beginning with his portraits, which are in folio.

Louis XIV. preſumptively from a picture by Bernard himſelf, an oval. Sebaſtian le Preſtre de Vauban, from F. de Troy; Charles Louis, count palatine, duke of Bavaria, from Vandyke, dated 1657. Louis Garnier, ſculptor and painter. Philippe, comte de Bethune. Anne Triſtan de la Beaume de Luze, archbiſhop of Paris, from F. de Troy.

Of his hiſtorical works, which are alſo of the folio ſize, the beſt are, "Attila, terrified by the Apparition of St. Peter and St. Paul in the Air, abandoning the Siege of Rome," from Raffaelle. "The Nativity of our Saviour," from Rembrandt. "Aſtyanax diſcovered by Ulyſſes in the Tomb of Hector," from S. Bourdon, a large plate. "A Repoſe during the Flight into Egypt," from Correggio. "The Crucifixion," from Ph. de Champagne. "The Body of Jeſus Chriſt before the Virgin," from the ſame. "The Aſcenſion of Jeſus Chriſt," from the ſame. "A Peaſant on horſeback, driving Cattle to Paſture," after Jean Foreſt. "The Image of Concord," an allegory from Le Brun. "A Shew of Cattle," from Caſtiglione. "Flight into Egypt," inſcribed "Dei, et matris, et filii, fugam in Egyptum," from Guido.

Jean Lanfant was born at Abbeville about the year 1615, and died at Paris, where he principally reſided, in 1674. He was the pupil of Claude Mellan, whoſe mode of engraving

graving he uſually imitated, but like all followers, was conſtantly behind his maſter. Many of his prints are performed with ſingle courſes of lines, like thoſe of Mellan; but he alſo imitated, with ſomewhat better ſucceſs, that artiſt's mode of engraving, wherein he employed croſs hatching. His plates are executed with the graver only, and though ſufficiently neat, are cold and taſteleſs.

The abbé Marolles collected an hundred and eighteen of this artiſt's productions, which are chiefly portraits, and of which the following are in moſt eſteem. They are all of folio dimenſions. Nicholas Blaſſet, architect and ſculptor to the king, inſcribed "Jo. Lenfant Abbavillacus ſc. Pariſiis, 1658. Franciſcus du Tillet, regis conſiliarus. Lenfant ad vivum faciebat, 1663. Franciſcus de Harlay, Rothomagenſis archiepiſcopus. Champagne pinx. Lenfant ſc. 1664. Ludovicus Boncherat, D. de Compana, &c. Id. fec. 1670. Ægidius la Maitre, dominus de Ferrieres, &c. Id. fec. 1662. Andreas de Pagot, ſupremi rei monetalis ſenatus. Id. fec. 1662. Henricus d'Argonges, abbas ſancti Quintini, Jo. Lenfant ad vivum faciebat, 1672. The buſt of our Saviour, after Raphael, an oval. "A Madonna with the Infant at her Breaſt," after Caracci. "The Virgin in the Act of Adoration," after Guido, oval. Joh. Lenfant del. et exc.

Louis Teſtelin was born at Paris in 1615, and died in the ſame city in 1655. He was the pupil of Vouet, and, according to the French writers, joined to a brilliant genius a correct taſte, and a love for ſtudy. So completely maſter was he of the theory of his art, that Le Brun himſelf was even not aſhamed to conſult him. In 1650 he was nominated profeſſor to the Royal Academy, and he continued his labours with indefatigable perſeverance.

His younger brother, Henry, equally diſtinguiſhed himſelf as a painter, and, like Louis, was nominated profeſſor to the Academy. He was the author of a work, entitled "Sentimens des plus habiles Peintres ſur la Pratique de la Peinture et Sculpture, mis en tables de preceptes, avec pluſiers diſcours Academiques, ou Conferences tenues en l'Academie Royale des dits Arts, &c." Par Henri Teſtelin, peintre du Roi, profeſſeur et ſecretaire en la dite Academie.

For this work Louis engraved ſeveral plates, and, among others, the following:

"The gathering of the Manna in the Deſert," after Pouſſin, in folio. "The Holy Family," from Pouſſin's celebrated picture at Verſailles, engraved in ſingle ſtrokes. "St. Michael's Victory over the Devil," which is alſo engraven without croſs hatchings. A ſet of fifty ſmall quarto plates, alſo executed for his brother's book, and from his own compoſitions, of which the ſubjects are children at play, and an expiring Chriſt, with the city of Jeruſalem in the back ground; an anonymous engraving, but one of the works of Teſtelin.

We are now arrived at the chronological ſtation of Sebaſtian Bourdon, of whoſe merits both as painter and engraver, we have already treated under the article BOURDON, SEBASTIAN: yet a more copious liſt of the engravings of ſo great a genius, than we were at that time enabled to give, may not prove unacceptable to the reader.

"The Return of Jacob," in folio. "Abraham's Servant accoſting Rebecca," in folio. "The Return of the Ark," in folio, a ſcarce and fine print, of which the compoſition is highly commended by ſir Joſ. Reynolds. "The Annunciation." "The Angel appearing to the Shepherds." "The Flight into Egypt," wherein the artiſt has introduced a mutilated ſtatue. Another of the ſame ſubject, in which Joſeph is watering his aſs. Another, in which the Holy Family are croſſing a wooden bridge, in order to reach a boat. Another, wherein the Holy Family are walking, and St. Joſeph leading the aſs. Another, in which the Virgin Mary is mounted on the aſs, which is led by St. Joſeph through ſome thickets. Another, in which St. Joſeph is ſeen leading the aſs by the bridle, in deſcending a hill. A Holy Family reſting, in which the infant Chriſt is feeding a lamb. Another, in which the infant St. John is ſeen holding the foot of the lamb. Another, here the Virgin is repreſented waſhing linen. This piece is beſt known under the title of "La Savonneuſe;" it is in quarto, and nearly ſquare. "The Baptiſm of the Eunuch," in folio. "Jeſus healing the Sick," in folio, nearly ſquare. "The Good Samaritan," in a landſcape, in folio. "A Peaſant giving Drink to one of his Children," in quarto. "Proſperity," in quarto. A ſet of five plates of the Senſes, in quarto. A ſeries of fourteen plates, repreſenting the liberal and the ſocial virtues, dedicated to M. de Colbert, in ovals and octagons. A ſeries of ſix grand landſcapes, in large folio, nearly ſquare. A ſeries of ſix beautiful landſcapes of a ſmaller ſize, in folio, and nearly ſquare. Two beautiful landſcapes, inſcribed S. Bourdon inv. ſculp. et exc. in folio. "The Seven Works of Mercy," with a dedication to M. de S. Bourdon.

Jean le Pautre, or le Potre, was born at Paris in the year 1617. In the early part of his life he was placed under a working goldſmith, where he acquired the firſt rudiments of ornamental drawing and engraving, and, in particular, acquired great facility in drawing with pen and ink, which probably led his mind to etching, while it helped to familiarize his hand to the uſe of the point. The authors of the "Manuel des Curieux et des Amateurs de l'Art," ſay that he alſo ſtudied under an architect, which ſeems highly probable, when we conſider the ſubjects of the greater part of his plates, which conſiſt of architectural decorations, vaſes, ceilings, and, in ſhort, ornaments of almoſt every kind, which are executed from his own deſigns, and abundantly prove the fecundity of his inventive powers. Florent le Comte juſtly ſays of him that "it is hardly poſſible to find an engraver who has produced more inventions than he," and that "every profeſſor of the liberal arts or mechanics, may find ſomething in his works which will at leaſt repay the trouble of examination."

Le Pautre was admitted a member of the French Royal Academy of Arts in the year 1677, and died at Paris in 1682. The ſtyle of his ornament, to ſay the beſt of it, is rather rich than elegant: it has been called ſolid; but it is too often cumberſome and heavy, when compared with the better taſte of the Greeks, or even that of the French in more recent times. The ſtyle of his engraving partakes of the ſame heavineſs, and his chiaro-ſcuro is deficient in harmony and tenderneſs. He muſt have both deſigned and engraved with great rapidity, for in the collection of Mariette were fourteen hundred and forty plates from compoſitions of his own; among the beſt of which, beſide his large volume of ornaments, the following may be mentioned: Portrait of himſelf, in a border of flowers, ſupported by genii, in folio, dated 1674. Louis XIV. ſeated in his cabinet in a Roman coſtume, dated 1634, a ſmall plate. The little good man, in folio: (this is the portrait of a mendicant friar). Portrait of Jean Robert, undertaker, in folio. Six plates of the hiſtory of Moſes, in folio. Twenty-two mythological plates, ſmall folio. Twelve landſcapes, with views of gardens and grottoes. Six plates containing fountains and jets d'eau, in the Italian ſtyle. Six plates in the manner of friezes, ornamented with various mythological ſubjects, in folio. Twelve plates of vaſes, adorned with children and mythological ſubjects, with figures in the antique ſtyle, in folio. Six plates of ſea-ports, in folio. Six plates of the viſions

viſions of Quevedo, each with its appropriate title, and eight French verſes, in quarto. Three large plates, each inſcribed with eight French verſes, relative to the coronation, conſecration, &c. of Louis XIV. Three large perſpective views of the canal of Fontainbleau, with the baptiſm of the Dauphin introduced, folio. Le Pautre alſo engraved a few plates after Paul Farinati, and he generally ſubſcribed his engravings with his initials, either J. P. or J. le P.

Pierre le Pautre was the ſon of John, whom we have juſt mentioned, and was born at Paris A.D. 1659, and died in 1744. He learned the principles of deſign, and probably of engraving, from his father, but his execution was more neat, and he worked principally with the graver. He has alſo been ſpoken of as a ſculptor with ſome approbation.

Pierre engraved ſeveral friezes; a figure of poetry for Perault's Cabinet des beaux Arts, publiſhed at Paris in 1690, and the pedeſtrian ſtatue of Louis le Grand, which was erected in the Hotel de Ville in the year 1639; an engraving which is rare and highly eſteemed, beſides other works of inferior note.

Euſtache le Sueur is not known to have etched more than a ſingle plate, which is of the quarto ſize, and the ſubject "An Holy Family." He was a painter of great celebrity, and of whom the French are juſtly proud; while his firm and upright character merits the reſpect of all men. For a detailed account of his life as a painter, ſee LE SUEUR.

François Chauveau was born at Paris in the year 1618, and died in the ſame city in 1676. He was the pupil of Laurent la Hyre, and painted ſmall pieces in a very pleaſing ſtyle; but he is better known by the vaſt number of his engravings. At the commencement of his career he employed the graver; but in a ſhort time he ſubſtituted the etching-needle in its ſtead, by which means he was enabled to finiſh, with greater celerity, the prodigious number of ſubjects which his fertile and lively genius engendered: for as the demand for his works was very great, and eſpecially by the bookſellers, he was obliged to finiſh them with great expedition. If his execution is not always pleaſing, we are at leaſt delighted with the ſpirit, ſtrength, truth, variety, and ingenuity of his compoſitions. In order juſtly to appreciate the merits of this artiſt, we ought not to form our deciſion from thoſe plates which were chiefly executed by the graver. In them he appears cold and diſagreeable, as may be ſeen in the prints of the Chartreux, which he engraved after le Sueur; whereas, in his etchings he is ſpirited and free.

Chauveau executed more than three thouſand plates, many of which were after other maſters, but the greater number from his own deſigns. It may ſuffice to mention the following, to ſome of which the name of Chauveau appears at length, and to others the cypher, which will be found in our plate.

Charles I. of England, in quarto. Jean Pierre Camus, biſhop of Bellay, in quarto. "The Pleaſures of Genius," in fifty figures, deſigned and engraven by Chauveau, in 1655, in quarto. "The principal Events of the Ancient Hiſtory of Greece," on nineteen plates including the frontiſpiece, in quarto. "Ovid's Metamorphoſes," by Benſerade, with an explanation of each ſubject, in quarto. "Philoſophical Fables of l'Eſclaches," by Chauveau and Richer, eleven pieces. Twenty-one plates for the poem of Clovis, by Chauveau and Nicolas Cochin. Twelve plates illuſtrative of the poem of la Pucelle d'Orleans, by Chapelain; and two hundred and forty-two for the medals of Fulvio Orſini, 1663. Chauveau alſo executed ſeveral prints in conjunction with Berain, la Moine, la Pautre, and Sylveſtre, for the collection of prints known under the title of the Cabinet of the King.

Subjoined are a few of the detached engravings of this artiſt, after his own deſigns, and thoſe of different maſters. "The Annunciation by the Angel," Chauveau inv. et fec. "A Repoſe during the Flight into Egypt." In this piece St. Joſeph is repreſented offering a flower to the infant Jeſus. "The Virgin Mary, her Son, the young St. John, and ſome Angels," inſcribed Chauveau pinx. et ſc. a ſmall plate, but finely etched, and finiſhed with taſte. "The Crucifixion." In this piece the Virgin, St. John, and Mary Magdalen, are repreſented at the foot of the croſs. Ib. inv. et ſc. in folio. "The Myſtery of the Holy Sacrament," 1678, on two plates. Two circular prints of "Meleager and Atalanta," and "Venus and Adonis," in folio. "Frontiſpiece to the Life of St. Bruno," in 4to. "Frontiſpiece for the Great St. Auguſtin," in 4to. "Frontiſpiece for the Poem of Charlemagne," in 4to. A "Theſis," with armorial bearings, and the four cardinal virtues. "Jeſus Chriſt at Table with the Diſciples at Emmaus," after Titian, in folio. This ſubject was alſo engraven by Maſſon. "A Concert," from Dominichino, in folio, a ſquare. This ſubject was likewiſe engraved for the cabinet of the king, by Picart. "The Life of St. Bruno," from le Sueur's pictures in the monaſtery of the Chartreux at Paris. A ſeries of twenty-two plates, in folio, engraved conjointly with le Clerc. "The Nativity of our Lord," after La Hire, in folio. "A Landſcape, with the Holy Family," from La Hire. "Meleager preſenting to Atalanta the Head of the wild Boar of Caledonia," after the ſame, in folio. "A triumphal Arch, a ſmall upright, for the Place Dauphine," after le Brun. "Apollo and Daphne," from Pouſſin, a middling ſized plate, dated 1667.

Nicolas Cochin was born at Troyes, in Champagne, in 1619, and died at Paris towards the end of the ſeventeenth century; he engraved a great number of prints, both of his own compoſition, and after other maſters. He imitated Callot in the ſtyle of his engravings; but he was more ſucceſsful in ſmall figures than when he attempted to execute large ones. The following are deemed ſome of his beſt performances:

A ſeries of ſubjects from the New Teſtament, eleven plates in 12mo. "The Martyrdom of the Apoſtles," a ſeries of ſixteen plates, in 12mo. A ſeries of battles in the ſtyle of Callot, ſix plates in 12mo. A ſeries of four plates, in which are repreſented the creation of the world; that of Adam and Eve; Adam eating the forbidden fruit, and Adam tilling the ground, in folio. "Melchiſedech and Abraham," in folio. "Abraham ſending away Hagar," in folio. "God promiſing the Land of Canaan," in folio. "The Children of Iſrael croſſing the Red Sea," dated 1645, in folio. "Pharaoh drowned in the Red Sea," in folio. "Moſes breaking the Tables of the Law," in folio. "The Adoration of the eaſtern Kings," in folio. "Repoſe in the Flight into Egypt," in folio. "Jeſus preaching in the Deſert," in folio. "Converſion of St. Paul," in folio "The Temptation of St. Anthony," in folio.

Beſides the above, Cochin engraved ſeveral plates after Rembrandt, Callot, Della Bella, and other maſters, ſome of which are contained in the works publiſhed by Beaulieu and Vulſon.

Noel, or Natales Cochin, was likewiſe a native of Troyes, and ſuppoſed to have been the brother of Nicolas. After exerciſing his profeſſion for ſome years at Paris, he retired to Venice, where he publiſhed ſeveral works.

It was this artiſt who engraved moſt of the plates for the work of Caroline Catherine Patin, daughter of the celebrated Charles Patin the phyſician, entitled, "Tabellæ ſelectæ

ſelectæ ac explicatæ a Carola Catherina Patina, Pariſiana Academica;" he alſo engraved a holy family from Titian, St. Anthony miraculouſly reſtoring a boy's foot, and a number of other coarſe etchings of little merit.

Charles le Brun, the great painter of the battles of Alexander, for the biography of whom, ſee the article LE BRUN, etched a few plates in a dark and bold, but maſterly ſtyle; among which, beſide the "Infant kneeling upon a Croſs," and "the four Parts of the Day," is a buſt of St. Charles Boromeo, an oval in folio, after his brother Gabriel's deſign.

Gabriel le Brun, the brother of Charles, was born at Paris in 1620. His talents were not of the moſt brilliant kind, either as a painter or engraver. It has been affirmed, though we ſhould hope without foundation, that ſo jealous was he of the fame of his brother, as thrice to attempt his life by poiſon. He engraved ſeveral pieces after Charles, as well as ſome from other maſters, among which we ſhall only mention the following.

Portrait of Charles Fevret de Saint Meſmin 1657, in folio, an oval. "An Allegory of the Peace concluded by Cardinal Mazarin," in folio. "Frontiſpiece to the Memoirs of Vittorio Siri," in folio. The "Twelve Apoſtles," after Charles le Brun, in folio. "The Redeemer," a large figure, from the ſame, in folio, on two plates. "Saint Martin," after the ſame, publiſhed by P. Mariette, in folio. "Saint Antony," after the ſame, in folio. A "Grand Theſe," dedicated to the parliament of Normandy; from the ſame, in folio. Another "Grand Theſe," dedicated to the parliament of Britanny, from the ſame. Gabriel alſo engraved ſeveral other pieces from Tintoret, Agoſtino Caracci, and other Italian maſters.

Bourguignon the battle painter, (for whoſe biography, ſee CORTESI,) performed about this time a few etchings on copper, which are juſtly admired and ſought after by collectors of French art. They are in a ſtyle of uncommon fire and freedom, and their chiaro-ſcuros broad and maſterly. The ſubjects of the principal of them are as follow:

A ſeries of eight plates of battles, ſubſcribed Giac. Corteſe fecit, ſmall. Another ſeries of four ſmall plates of battles ſubſcribed with his initials only.

The battles contained in the firſt edition of the hiſtory of the wars in Flanders, from Flam Strada, in 4to. are alſo attributed to this artiſt.

Guillaume Courtois, or Corteſi, the brother of Bourguignon, was born at St. Hippolito in Franche Compte in the year 1628, and died at Rome in 1679. He went to Italy at an early period of life, where he frequented the ſchool of Pietro da Cortona, and ſuch was his merit as a painter, that Carlo Maratte heſitated not to prefer his works to thoſe of his maſter. His deſigns may perhaps be more correct, but a certain coldneſs pervades his compoſition. His engravings are few in number, and the following will probably be found to be the beſt of them.

"The Plague, in which Tobias is ſeen burying the Dead," A. Weſterhout exc. in folio, nearly ſquare. "A glorified Virgin Mary," in folio. "The Adoration of the Kings," inſcribed Guil. Corteſe del. in folio. "The Preſentation of Chriſt in the Temple," after Paul Veroneſe, in folio. "The Reſurrection of Lazarus;" after Tintoret, in folio. "Chriſt healing the Sick," in folio.

The Courtois had another brother who was alſo named Guillaume, and who is ſaid to have been likewiſe a good painter. As he became however a capuchin friar in his youth, and only travelled reſpecting the concerns of his order, very little is known concerning him.

Iſrael Silveſtre was born at Nancy in the year 1621, and died in 1691 at Paris, where he had taken up his abode. The pupil and nephew of Iſrael Henriet, he diſplayed ſo much taſte and judgment in his views and other landſcapes, that Louis XIV. employed him to deſign and engrave the royal palaces, as well as the public feſtivals, and the principal places conquered by his arms. He afterwards was honoured with the title of maſter and deſigner to the Dauphin, accompanied with the grant of a penſion and apartments in the Louvre.

Silveſtre died in the month of October, at the age of ſeventy years, leaving behind a moſt reſpectable character and ſeveral children, of whom his ſon Louis was afterward diſtinguiſhed by being invited to the court of Dreſden, where he enjoyed the title of firſt painter to Auguſtus III. king of Poland and Elector of Saxony, and where he remained thirty years.

In the courſe of his life Silveſtre twice viſited Italy, whence he brought back a great number of ſketches and drawings, which he afterward engraved. The ſmall figures with which he peopled his landſcapes are executed with taſte and ſpirit. In the ſtyle of his landſcapes themſelves, his French biographers ſay, that he imitated Callot and Della Bella, and was in his turn imitated by le Clerc; but there is a certain freedom and felicitous feeling in the line of Silveſtre, that has very rarely been equalled, and perhaps, as applied to certain objects, has never been excelled. His winding roads, his various buildings, his broken ground, &c. are moſt taſtefully delineated, without being pranked into the French picturesqueneſs of the old ſchool; and his freedom and felicity of outline, being its ſureſt teſt, ſeems to proclaim *originality*. It ſhould further be obſerved, that the artiſt whoſe originality of ſtyle has merited and received the general approbation, deſerves always to have that circumſtance recorded to his honour, where it can be ſo recorded with certainty. Now though it be true that Della Bella, Callot, and Perelle, were the contemporaries of Silveſtre, yet the latter, (a ſomewhat younger man indeed,) is known to have etched the grounds and buildings in ſome of Callot's plates, which circumſtance, eſpecially when coupled with the internal evidence deducible from ſtrong and fine feeling, affords a ſtrong preſumption, that Silveſtre was the firſt French engraver who in his etchings delineated landſcape with taſte.

The whole number of engravings by this artiſt, amounting to more than a thouſand, we ſhall here reſtrict ourſelves to the mention of only the moſt diſtinguiſhed.

A ſet of four plates of the ſeaſons perſonified. A ſet of views in Italy and France, with French inſcriptions, twenty-one plates. Views of different edifices in Rome, and the environs, publiſhed by Iſrael Henriet, with explanations in French, thirteen plates including the title, in 8vo. Another ſet of twelve views in Italy and France, with buildings and ſmall figures. Another ſet of views, ornamented in the ſame manner, with explanations in Italian and French, twelve pieces in 8vo. Another ſet of twelve under the title of "Alcune Vedute de Giardini et Fontane di Roma e di Tivoli, deſignate et intagliate per Iſrael Silveſtre," with explanations in Italian. Four views, three of Rome, and one of the village of Flovelle, near Nancy, in 8vo. Another ſet of eleven plates, ſome of which appear to be by Della Bella, of views in Italy, with explanations in the Italian language, in 4to. Another ſet of eighteen topographical landſcapes, (views in France,) publiſhed by Iſrael, and dedicated to Louis de Crévant, marquis of Humieres, in 4to. Another topographical ſet of ſeven views in France, of the quarto ſize, "taken on the ſeveral ſpots by Iſrael

Silveſtre." Views in the kingdom of Naples, with explanations in French, four pieces in 4to. in the form of friezes. Different landſcapes in the duchy of Burgundy, "taken on the ſeveral ſpots by Iſrael Silveſtre," with explanations in French, twelve pieces 4to. In the form of friezes. A ſet of four plates of the environs of Nancy. A book containing views in France, Rome, and Florence, by Iſrael Silveſtre, with explanations in French, twelve beautiful plates, in 4to. The ſea-ports of Italy, on twelve quarto plates, in circles. Another ſet on ſix plates of ſea-ports in Naples, and its environs, by Iſrael Silveſtre, dated anno 1648, and alſo in circles. Views of the moſt remarkable places in Paris, and the environs, taken by Iſrael Silveſtre, with a dedication, and to each ſubject an explanation contained in four French verſes, twelve plates in 4to. Several of this beautiful ſeries were engraven by Della Bella. Views of the principal edifices in Rome, and other parts of Italy, four of which are of Venice, twelve pieces in 4to. A beautiful ſet. Another ſet, with deſcriptions in French, of Venetian topography, on twelve plates in 4to. Views of the caſtle and other buildings of Fontainbleau, by Iſrael Silveſtre, with explanations in French, ten plates, in 4to. Views of the chapel and houſe of the Sorbonne, founded by cardinal Richelieu; (the architect Jaques le Mercier,) together with ſeveral handſome chateaus in different parts of the kingdom, twelve plates in folio, with explanations. Views of the palace of Orleans, and of Luxembourg, with ſeveral other houſes and gardens in the environs of Paris, twelve pieces in 4to. Views in the environs of Paris, with explanations, twelve pieces, the frontiſpiece to which is engraven by Claude Gayrand, in folio. This ſet includes, by a ſtrange aſſimilation, a view of the church of St. Sophia at Conſtantinople. Another folio ſet of eighteen views of monuments, &c. in Rome, and other Italian cities, accompanied with explanations in French and Italian. Another folio ſet of ſeven plates, including the title, of Rome and its environs, taken by Iſrael Silveſtre. The ſubjects of this folio ſet are the church of St. Peter; the garden of Montalto, the palace and garden of Ludoviſe, the bridge of Limentane near Rome, St. Agnes without the gates of Rome, and the arch of Conſtantine. The churches named "the Stations of Rome," with a title and dedication on ten folio plates, comprehending views of the churches of St. Peter, St. Paul, St. Croix, St. John de Latren, Marie Maguere, St. Sebaſtian, St. Lawrence, St. Marié del Popolo, the Annonciade, and St. Paul of the three fountains, with Latin and French explanations. Topography of Nancy and its environs by Iſrael Silveſtre, a native of that city, twelve pieces with explanations; the two laſt of which views are engraven by Perelle, in folio. Perſpective views of the Cardinal palace, from the garden, the Louvre, and the Thuilleries, as well as of other celebrated places in the environs of Paris, by Iſrael Silveſtre, with deſcriptions in French, ten pieces in folio. A collection of views of chateaus and villas, drawn on the ſeveral ſpots by Iſrael Silveſtre, with deſcriptions, ten folio plates. Another collection of views, on ten plates, dedicated to his majeſty. Another collection of twelve folio perſpective views of chateaus and gardens, taken on the ſeveral ſpots, and publiſhed by Iſrael Silveſtre, in 1651. View of the Mazarin palace, with the gardens and edifices on mount Quirinal, inſcribed Iſrael Silveſtre incidit, a large piece in folio. Perſpective view of the city of Rome, with an explanation of the principal edifices and ſites dependent on it, very large, and engraved on four plates. View of Rome, with a part of the city in perſpective, and a ſide view of the church of St. Peter. Silveſtre fecit, excudit Pariſiis, a large folio plate. Beneath which are twenty verſes by Scudery. Another perſpective view of Rome, with its edifices and ruins, a large folio, in the form of a frieze. Perſpective view of Paris, taken from the bridge of the Thuilleries, with references to the principal edifices, in folio. Two large perſpective views of Charité and Nevers, with inſcriptions in Latin and French. De Lincler del. Is, Silveſtre ſculp. long friezes. An excellent large, and very rare print, a view of the Coliſeum at Rome, dated 1653. Perſpective views of Stenay, Sedan, Montmedi, Verdun, and Metz, a ſet of five large folio plates. "The grand Carouſal," or royal entertainment given at Paris in the year 1662, conſiſting of an hundred and eight prints, in the execution of which Silveſtre was aſſiſted by F. Chauveau. "The Pleaſures of the enchanted Iſland," dated in 1664, engraved on nine folio plates which were accompanied by a vignette, and publiſhed at Paris.

Jaques Prou was born at Paris A.D. 1639, or thereabout. He ſtudied under Seb. Bourdon and executed various etchings, ſome of which were from the works of his maſter and other painters, and the reſt from his own deſigns. The following are a few of his beſt pieces, all of which are of the folio ſize. A ſet of twelve landſcapes of his own compoſition. A ſeries of ſix grand landſcapes, of a wild and ſavage character, after Seb. Bourdon, large folio. "The Flight into Egypt;" after Aug. Caracci, and "St. John baptizing our Saviour in the River Jordan."

François Colignon was born at Nancy about the year 1621. He acquired the elements of engraving under Callot, whoſe ſtyle he adopted, ſtudying alſo the works of Della Bella and Silveſtre. In 1640, he viſited Rome, and, during his ſtay in that metropolis, executed ſeveral pieces both from his own deſigns, and after thoſe of other maſters. On his return to France, he engraved, for the grand collection of Beaulieu, ſeveral views of the cities conquered during the reign of Louis XIV.

The following are from his own compoſitions, a ſet of twelve landſcapes, in folio. A ſeries of pieces entitled, "The witty Inventions of Love." "The Buildings of Rome under the Pontificate of Pope Sixtus Quintus." "A Plan of the City of Malta, with the ancient Fortifications."

From the deſigns of other painters, he engraved, "The Flight of Attila," after the celebrated picture of Raphael in the Vatican. "The Canonization of the five Saints, St. Gaetan, St. Francis Borgia, St. Philippe Benizio, St. Bertrand, and St. Roſe," after J. B. Gaetano, in folio. "A View of Florence," drawn by Della Bella, in folio. "Plan of the Chateau de Moyen," formerly called Quinguengrogne, drawn by Callot, and a book containing nineteen prints in 4to. from the compoſitions of L. Valerio.

Dominique Barriere was born at Marſeilles in the year 1622. He viſited Rome about the middle of the 17th century, and during his ſtay in that city publiſhed a great number of prints engraven in a ſtyle, having ſome reſemblance to that of Della Bella. He either inſcribed his works with his name in the following manner, Dominicus Barriere Maſſilienſis, or with his cypher, which will be found among our monograms of the French ſchool. Among others, the following pieces are from the hand of this maſter:

Portrait of John de la Valette, grand Maſter of Malta, in profile, marked D. B. in folio. This is a very ſcarce piece. A ſet of ſix landſcapes, Roſſi ex cudit, in folio. A ſet of 12 landſcapes, dedicated to Lelio Orſini, and dated 1651, in folio. Series of ſeven views of the villa of Aldobrandini, engraved in 1649, and inſcribed Dominicus Barriere Maſſilienſis, in folio. Landſcape, in which is ſeen the zodiac, with this inſcription: "Vim profert ubi maximam,

ſmam, in folio. View of Freſcati, and its environs, in folio. "Pontana magiore nel Giardino di Tivoli, Vicino al organo," in folio, with the cypher of the engraver. "Statue e Vedute della villa Pamfili." Roſſi exc. in thirty-four middle ſized pieces. "Catafalco e aparato nella chieſa di S. Vincenzo e Anaſtaſio, pen. Effequie del cardinal Mazarino," four pieces in folio. "Sepulchral Monument of Nicolao Ludoviſi Plumbini, la Collegio ſac. Jeſu. Dominicus Barriere Gallus inventor, exegit, delineavit et ſculpſit," in folio. "Hercules ſitting, from a bas relief, in the Garden of the Palace of de Medicis," inſerted in the book of the Heſperides of P. Ferrari, in folio. "Circum Urbis Agonalibus ludis olim celebrem, dicata triumphali pompo Chriſto reſurgenti Hiſpana pietas celebriorem rediddit." Anno Jubilei 1650. Eques Rainal Archit. Dominicus Barriere maſſ. del. et ſc. This, ſay the French writers, is a ſuperb piece, enriched with a vaſt number of figures. "The Hiſtory of Apollo," engraved on ſeveral plates, after the paintings of Dominichino and Viola, in the Villa Aldobrandini.

Beſides the above, Barriere executed various other works, after Cortona, Bologneſe, Claude of Lorrain, Titian and other maſters.

Gabriel Perelle deſigned and engraved landſcape with conſiderable ſucceſs. He was a native of Paris, born ſome time about the year 1622; and, in conjunction with his ſons Adam and Nicholas, produced a very great number of plates, ſome of which are views, but the far greater part engraved from his own original compoſitions.—In point of drawing, his prints are far above mediocrity; but his chiaro-ſcuro wants breadth, his lights are too much ſcattered; and he ſeems to have endeavoured to compenſate for this want of breadth by the depth of his ſhadows, which has rendered his effects ſpotty; and in conſequence of his employing the point too little, and the graver too much, the ſtyle of his engraving is ſomewhat heavy and dry.

But notwithſtanding theſe defects, Perelle was a meritorious artiſt, and ſhould be ranked high among the landſcape engravers of France; though the foliage of his trees be defective in natural expreſſion, the ruined temples and other edifices which abound in his works are almoſt always taſteful and pictureſque. His imagination, ſtored by contemplating the works of Claude, the Pouſſins, Dominichino, and his great predeceſſors in landſcape, was lively and productive; he underſtood much of the principles of compoſition, and in conſequence, often attains elegance, and ſometimes conſiderable grandeur.

The engravings by this family, of whom the father appears to have been the ſuperior artiſt, are generally inſcribed "Perelle inv. et fecit." The whole have probably never been enumerated, but ſeven hundred and ſixty of their prints are known to have been in the poſſeſſion of the abbé Marolles in the year 1666, whilſt the artiſts were yet living. Of theſe a large proportion are from the compoſitions of the ſenior Perelle, and were publiſhed in ſets, generally conſiſting of four each, of the quarto ſize, and circular form, but without any titles beneath. As it would be endleſs to deſcribe theſe, we can only ſay in general that there are at leaſt a dozen of theſe ſets, conſiſting chiefly of mountain ſcenery with rocks, ruins, trees, and figures. Ruined edifices ſeen by moon-light conſtitute the ſubjects of one ſet; and at leaſt two ſets are of ſhipping and ſea ports. Of the remainder of Perelle's works, the following will probably be found moſt worthy of notice.

Four views in the gardens of Verſailles. A pair of do. The grotto of Rouel and the fountain of Tivoli, in folio. Five ſeveral pairs of folio landſcapes with appropriate figures. A pair of views, one of the gate of conference, the other in the gardens of St. Cloud, then the palace of the archbiſhop of Paris, in folio. A pair of views in the gardens at Fontainbleau. A ſet of four, alſo of the folio ſize, and from drawings by Silveſtre, *viz.* The church of St. Michael of Dijon; the palace of Dijon; the bridge of Grenoble, and the Point Reale of Marſeilles. Four views in Paris: *viz.* The arſenal and the mall, the Pont Neuf and the Ile du Palois; the Louvre, and the gate of Neſle; and the Mall with the adjoining fields. Silveſtre del. Perelle ſc. in folio. Four provincial views, namely, the baths of Bourbon d'Archambaut; the holy chapel of Bourbon d'Archambaut; the chateau of Bourbon Lancy, and its baths in the time of Julius Cæſar; and the Grand Chartreuſe near Grenoble; drawn by Silveſtre, in folio. Six views of the moſt beautiful ſcenes in the garden of Ruel. Iſrael Silveſtre del. Perelles ſculp., in large 4to. Two mountainous landſcapes, with buildings and ruins, in the one Abraham is repreſented diſmiſſing Hagar, and in the other the good Samaritan, from P. Bril, in folio. "The Adoration of the eaſtern Kings," the figures ſmall and ſurrounded by ruins, after C. Poelenburg, in folio. "The Defeat of the Spaniſh Cats by the French Rats," a ſatirical print, engraved on the occaſion of the ſurrender of Arras in 1642, with ſix explanatory verſes. L. Richer, inv. G. Perelle ſc. This piece, which is extremely ſcarce, was ſuggeſted by the following circumſtance. During the ſiege, the inhabitants of Arras affixed the following inſcription upon one of the gates: "Quand les François prendront Arras, les Souris mangeront les Chats." (When the French ſhall take Arras, the Mice will eat the Cats.) After the fall of the city, the inſcription was altered by the Frenchmen obliterating the p.

Jean Couvay was born at Arles A.D. 1622, and enjoyed the reputation of being one of the beſt French engravers of the ſecond claſs. His ſtyle poſſeſſed much eaſe, and reſembles that of Villamena. He executed both portraits and hiſtorical ſubjects, after his own deſigns, as well as from thoſe of other artiſts; and moſt of his prints are marked with his cypher, which will be found among our monograms of the engravers of the French ſchool. The following are a few of his beſt productions.

"The Virgin Mary preſenting ſome Pinks to her Son, whom ſhe holds on her Knees," after Raphael, inſcribed "Dilectus meus mihi et ego illi," in folio. "John the Baptiſt in the Deſert," after the ſame, in folio. "St. Benedict tempted by the Demon of the Fleſh, whom he puts to flight by preſenting a Crucifix." A night piece, after Guercino, in folio. "A Madonna," after Blanchard, in folio. A half-figure of an "Afflicted Magdalen, deſpoiling herſelf of her Raiment," after Le Brun, in folio. "The Aſcenſion," in which the portrait of the painter is ſeen among the apoſtles, after Jac. Stella, in folio. "Cleobulus, one of the ſeven wiſe Men of Greece," after Cl. Vignon, in folio. "The Martyrdom of St. Bartholomew," after Pouſſin, in folio, one of the beſt engravings of Couvay. A pair after G. Huret, which are entitled "The Reſidence of the Faculties of the Soul," and "The beautiful Abode of the five Senſes," in folio, engraved in imitation of the ſtyle of Ab. Boſſe.

Among the portraits of Couvay, the moſt eſteemed are, An effigy of brother Simon Diſſy, a lay capuchin, and Louis XIV. on horſe-back, preceded by Fame, after J. Bourdon, in 4to. the frontiſpiece to the poem of Clovis.

Sebaſtien Vouillement was born at Bar-ſur-Aube about the year 1622. He acquired the elements of deſign under Daniel Rabel, and engraved ſeveral plates both at Paris and Rome, where he reſided for a conſiderable time, but they

poſſeſs very little merit. He frequently uſed the cypher which is given in our plate of French monograms. The following are a few of the works of this artiſt :

"A Gypſey fore-telling good Fortune to a Youth," inſcribed with twelve French verſes, in folio. This is better than moſt other of the engravings of Vouillement. "Pope Urban VIII. pronouncing the Benediction," inſcribed S. Vouillement ſc. Romæ 1642, in 4to. "An Author writing," from Pouſſin, for the Documenti d'Amore, with the cypher of the engraver, in 4to. After Raphael he has engraved, in folio, "The Maſſacre of the Innocents," from two different compoſitions. "Mount Parnaſſus," from the picture in the Vatican, and "An Holy Family." "The betrothing of St. Catherine," with "St. Joſeph" and "St. Cecilia," are all from Albano, and in folio.

Jean Peſne (called Penna by the Italians) was born at Rouen in the year 1623, and died at Paris in 1700. It does not appear under whom he ſtudied, and Strutt, with great probability, conjectures that he was brought up under ſome painter, perhaps Nicholas Pouſſin, from whoſe pictures the greater part of his engravings are taken. He etched in a ſlight, coarſe, and irregular ſtyle, and finiſhed his plates with the graver, harmonizing and blending his work by means of ſtippling. Watelet ſays of him, ſomewhat ſeverely, that "his ſtyle of execution is neither agreeable, ſcientific, nor pictureſque;" but the ſuperior merit of fidelity to the effect of his original belonged certainly to Peſne; notwithſtanding the dryneſs and roughneſs of his ſtyle, his maſſes of light and ſhade are broad and clear; yet he did not detail his forms with ſufficient accuracy, and it has been juſtly aſſerted of him by Strutt, that had "the heads and other extremities of his figures been more carefully attended to, it might have been ſaid that the ſpirit of that admirable painter (Pouſſin) was never better expreſſed than by this artiſt;" but an exception very properly follows, in favour of Gerard Audran, and probably another ought to have followed in favour of Claudia Stella.

The beſt of his engravings are, two portraits of N. Pouſſin, from pictures by himſelf, middle-ſized upright folios, one dated in 1649. From the ſame maſter, and of the folio ſize, are "Eſther, before Ahaſuerus," in folio. "The Nativity, or Adoration of the Shepherds." "The Body of Chriſt extended near the Sepulchre, with Mary and St. John weeping." "Chriſt laid in the Sepulchre." "The Death of Sapphira." "A Madonna, with the Infant Chriſt, and the little St. John." "A Holy Family," dedicated to C. le Brun. "St. Paul taken up into the third Heaven." "The Teſtament of Eudamidas of the City of Corinth." "The Triumph of Galatea." "Summer, with the Story of Boaz and Ruth." "Autumn," the figures introduced into which are the two ſpies bearing a bunch of grapes from the promiſed land. N.B. The two other ſeaſons, which compleat the ſet, are engraven by J. Audran. A ſet of nineteen plates, including the frontiſpiece of the Labours of Hercules, from the paintings of Pouſſin, in the grand gallery of the Louvre. The manner in which the engraver has conducted his lines in theſe engravings is highly commended by Huber and Roſt. "The Seven Sacraments," from paintings formerly in the Palais Royal, and now in the collection of the moſt noble the marquis of Stafford, at Cleveland houſe, namely, "The Baptiſm," or John baptizing Jeſus in the waters of Jordan; "The Supper," or Jeſus at table in the houſe of Simon the Phariſee, with Mary Magdalen at his feet; "The Confirmation," given by the high prieſt; "The Euchariſt," or Jeſus holding the Paſſover with his Diſciples; "Extreme-Unction" adminiſtered to a dying man, ſurrounded by his weeping Family; "The Charge," or Jeſus delivering the keys to St. Peter; and "Marriage," or the affiancing of Joſeph and Mary, large folio plates.

The following pieces are after other painters of the Italian ſchool "A Holy Family," from Raphael's celebrated picture in the Orlean collection, in folio. In this piece Mary is repreſented holding the Infant Chriſt, whom St. John embraces, while St. Joſeph is ſeen at a little diſtance walking behind a thicket. A ſeries of landſcapes, with a frontiſpiece, by Jean Peſne, named here (at Rome) Gio. Penna, in fifteen plates, in folio, a production highly valued by connoiſſeurs.

Among his portraits, the two following are moſt eſteemed, Louis le Comte, ſculptor to the king, (inſcribed J. Penne pinx. et ſculpſit,) in folio, and Francis Langlois, called de Chartres, bookſeller, after Van Dyke, dated 1645, and alſo of the folio ſize.

Francois de Poilly was born at Abbeville A.D. 1622, and died at Paris in 1693. De Poilly was the ſon of a goldſmith, and the goldſmiths of the ſeventeenth century exerciſing alſo, in the ornamental parts of their work, conſiderable ingenuity in the arts of engraving and deſign, he acquired the rudiments of his future profeſſion under his paternal roof. He was afterward ſent to Paris, and placed under the tuition of P. Daret, (who had been the pupil of Bloemart,) with whom he remained three years; but being ſtill deſirous of acquiring more extenſive profeſſional knowledge, he went to Italy, and reſided ſeven years in the city of Rome, where he engraved ſeveral very capital ſubjects, from the great painters of that time, and their ſtill greater predeceſſors.

De Poilly worked with the graver only, and may juſtly be ſpoken of as one of the moſt ſkilful artiſts in the management of that inſtrument, that France ever produced, at leaſt till Europe was ſurprized by the tranſcendent manual powers of Wille and Bervic. His engravings are bold, firm, and clear, and are finiſhed with great accuracy; but from want of variety in the handling of his graver, the fleſh, draperies, and back grounds of his figures are not ſufficiently diſtinguiſhed from each other, and hence his works have much of the heavineſs and coldneſs of a leaden ſtatue. Rectangular croſſing was the prime element of his ſtyle; powerful ſecond courſes of lines were thrown over his firſt courſes, ſo as to form a ſmall ſquare between the interſections of every four lines. His outline however is drawn with great care and preciſion; in the characters of his heads he faithfully copied his originals, and his extremities, in general, are well rendered.

On his return from Italy de Poilly ſettled in Paris, where he not only purſued his profeſſional labours with his wonted aſſiduity, but likewiſe inſtructed a great number of pupils, both foreigners and of his own country; notwithſtanding whoſe aſſiſtance, it is not eaſily conceivable how he produced the very great number of plates which bear his name, when we reflect that many of them are large, and all the reſult of conſiderable care and patience. His engravings conſiſt of hiſtorical ſubjects and portraits, of which we ſhall proceed to mention ſome few of the moſt remarkable, beginning with the latter.

Louis XIV. when a youth, after J. Nocret; Henry d'Arnaud, biſhop of Angiers; Jerome Bignon, counſellor of ſtate, after Philip Champagne, dated 1664; Abraham Tabert, mareſchal of France, after L. Ferdinand; Cardinal Mazarin, after P. Mignard; Guillaume de Lamoignon, ſurrounded by allegorical figures of Virtue, Probity, and Candour, from the ſame painter; and a buſt of the ſame original, as large as life. The above are all of the folio ſize, and there

there is a portrait of de Poilly himſelf, engraven by his pupil J. L. Rouillet in the year 1699, from a drawing by his maſter, done in the year 1680, and inſcribed Francois de Poilly, engraver to the king.

The following hiſtorical works are alſo of the folio ſize: "The Holy Family," in a landſcape of a circular form, in which St. John is embracing the Infant Jeſus. "St. Ignatius de Loyola on his Knees." "St. Francis Xavier dying among the Indians." "The grand Triumph of Auguſtus." "The Viſion of Ezekiel," from a picture of Raphael, in the gallery of the Palais Royal. "A Holy Family," after Raphael, in which the Infant Chriſt is repreſented ſtanding on his cradle, an upright. "The Madonna raiſing a Veil to ſhew the ſleeping Saviour to St. John," from the ſame maſter, and of the upright form. (N.B. The firſt impreſſions of this plate are before the croſs lines were engraved on the veil.) The print is known among foreign connoiſſeurs by the appellation of "La Vierge au linge." "The Nativity," a large upright, in an octagonal border, from Guido, one of the beſt of de Poilly's engravings. The early impreſſions, which are now become ſcarce, were taken before the ſmall angels, which in the later impreſſions appear above, were inſerted. "The Flight into Egypt," from the ſame painter, in which Guido has introduced the poetic idea of an angel ſtrewing with flowers the path of the holy travellers. "Jeſus Chriſt at Prayers on the Mount of Olives," from the ſame. "A dead Chriſt," from a capital picture of Caracci. "Chriſt bearing his Croſs," from the ſame. "Nymphs bathing, in a Landſcape," after Julio Romano. "The overflowing of the Nile," after a deſign by Algarde. Views of two ſides of the grand obeliſk of the emperor Caracalla, erected at the fountain of Bernin, in the Place de Navonne, a pair of large uprights. "A Holy Family," after a picture of Pouſſin, in the Houghton gallery. "The Marriage of St. Catherine," after P. Mignard, a large upright. "The Baptiſm of Jeſus Chriſt," inſcribed "Hic eſt filius," after the ſame, a large upright. "St. Charles Boroméo adminiſtering the Sacrament to thoſe ill of the Plague at Milan," from the ſame. A capital piece both in reſpect to painting and engraving. "Mercury receiving the Order from Jupiter to convey the Infant Bacchus to the Nymphs," from Alexandre. "The Viſitation," from C. le Brun. "St. John in the Iſle of Patmos," from the ſame. "The Crucifixion," a large upright, from the ſame. "The Deſcent from the Croſs," after the ſame. "Grand Theſé of the abbé Tellier," in which Time holds up the portrait of Louis XIV., after the ſame, two plates, ovals. "Grand Theſé of Duke Albert, in which Louis XIV. clothed in a royal Mantle, appears ſeated, and ſupporting himſelf upon his Truncheon," dated 1663, in two plates. "Grand Theſé of M. de Segnelai, in which Louis XIV. clothed in a Roman Habit, is accompanied by Minerva and Power," after the ſame, in two plates. Grand Theſé, the ſubject of which is "The Diſpute between Minerva and Neptune, reſpecting the Name to be given to the City of Athens," after le Brun. "The Parable of the Gueſt, without a wedding Garment," after Ph. Champagne. "A grand Crucifixion," where the Saviour is on the point of expiring, uſually termed "Le Chriſt des Chartreux," from the ſame, in three plates. "The Aſcenſion," after the ſame. "Joſeph's bloody Coat preſented to Jacob," after Ant. Coypel.

Nicolas de Poilly, the brother, and in ſome ſort the pupil of the former, was alſo born at Abbeville in the year 1626, and died at Paris in 1696. He was an excellent deſigner and engraver, though ſomewhat inferior to his elder brother, whoſe ſtyle of engraving he ſucceſsfully imitated. He engraved a great number of portraits, as well as hiſtorical ſubjects, which are very much valued by connoiſſeurs for the neatneſs and preciſion of their execution. The following are a few of the ſubjects, which he engraved after different maſters:

"A Head of the Virgin Mary," without the painter's name, which is however Champagne. "St. Auguſtin holding a Crucifix," from the ſame, an upright folio. "A Holy Family," in which two angels are ſeen ſupporting a baſket of flowers; from S. Bourdon, in folio. "The Nuptials of St. Catherine," from the ſame painter. "The Preſentation in the Temple," from le Brun, in 4to. "The Return of the Holy Family from Egypt," after the ſame, in 4to. "The Holy Family, with the Virgin having the Infant Jeſus aſleep on her Lap," from the ſame; a celebrated piece, known under the name of the *Silence*, in folio. "Repoſe during the Flight into Egypt," Chaprin pinx. in folio. "Chriſt on the Croſs between the two Thieves," from Pouſſin. Note, This ſubject is engraved in a much ſuperior ſtyle by Claudine Stella.

Among his beſt portraits are thoſe of Louis XIV. in a frame ornamented with laurels, an oval, ſurrounded by angels bearing emblems, after N. Mignard of Avignon. Louis XIV. dated 1683, the head of the natural ſize. Maria Thereſa, queen of France, 1680, of the ſame form and dimenſions. Louis, dauphin of France, ſon of Louis XIV. of the ſame ſize. Marie Anne Victoire de Baviere, dauphineſs of France, of the ſame ſize. Louis de Bourbon, ſtyled the Great Condé, of the ſame ſize. Pierre du Cambout de Coiſlin, grand almoner of France, biſhop of Orleans, of the ſame ſize. Francis de Borgia, a Jeſuit. Francis de Coetlogen, biſhop of Rennes. René Potier, duke of Geſvre, peer of France; after Cl. le Fevre. Nicholas Edward Olier, counſellor to the king, after the ſame. Noel de Bullien, marquis of Gallarden, regiſtrer to the king; theſe are all of the folio dimenſions.

Jean Baptiſte de Poilly, the ſon of Nicolas and nephew of Francis, was born at Paris in 1669, and died in the ſame city in 1728. After having acquired the elements of deſign and engraving, he viſited Rome, with the view of improving his knowledge of theſe arts. On his return to his native country, he diſtinguiſhed himſelf by ſeveral works of merit, in conſequence of which he was admitted a member of the Royal Academy. His ſtyle of engraving did not much reſemble that of his father and uncle; he advanced his plates conſiderably in the etching, and further improved upon the manner of his inſtructors by mingling ſtippling with his courſes of lines. By this method he produced a very picturesque effect, both in his portraits and hiſtorical ſubjects; and acquired great honour in his own country, by engraving Mignard's gallery of St. Cloud.

Among other ſubjects, the following were engraved by him, after different maſters:

"The Nativity of Chriſt," after Gaudentio Ferrari. "Danae in a golden Shower," from a cartoon of Julio Romano, in the cabinet of the duke of Orleans, in folio. "The Virgin worſhipping the Infant Chriſt," after Benvenuto Garofalo, in folio. Note, The three latter are in the Crozat collection. "The Martyrdom of St. Cecilia," after Dominichino, an upright folio, intended as companion to the "Alms of St. Cecilia," engraved by Francis de Poilly (his brother) after the ſame painter. "The Nativity," after the picture of Carlo Maratti, in the cabinet of the king; a beautiful piece, in folio, almoſt ſquare. "Aaron's Rod, changed into a Serpent, devouring thoſe of the Magicians;" after Pouſſin, in folio. "The Adoration of the Golden Calf," from the ſame, in folio. "The Holy Family," inſcribed "Sacra Chriſti Familia;" after the

ſame, from the cabinet of the king, in folio. The grand ſaloon at St. Cloud, (by Mignard) namely, "The Banquet of the Gods;" "The Workſhop of Vulcan;" "The God Pan, accompanied by Bacchantes and Fauns," and "Mars and Venus accompanied by the Loves and Graces;" beſide which, belonging to the ſet, are eight plates of Caryatides, richly ornamented. "Faith and Hope," two emblematical pieces, after the ſame, in folio. The four ſeaſons, painted in the gallery of St. Cloud, after the ſame. "Spring, the Nuptials of Flora and Zephyrus." "Summer, Sacrifice in Honour of Ceres." "Autumn, the Triumph of Bacchus and Ariadne." "Winter, Cybele imploring the Return of Sol," in folio. A ſtatue of Truth, after Bernini, in folio. "The Judgment of Solomon," after Antoine Coypel, in folio. "Suſanna accuſed by the Elders," after the ſame. A pair, "Neptune armed with his Trident, and ſtanding on a Dolphin," and "Jupiter graſping Thunder, and ſeated on a Cloud," inſcribed Fr. Verdier inv. J. de Poilly ſc. in folio.

His beſt portraits are thoſe of Corneille van Cleve, ſculptor, painted by Vivien. Francis de Troy, painter; from a picture by himſelf. Clement XIII. Pontifex max. Prince Charles Edward Stuart, a whole length figure on foot, after Dupra. Louis XIV, after Mignard. They are all of the folio ſize.

Nicolas Loir, the ſon of a goldſmith, was born at Paris in 1624, and died in the ſame city in 1679. He frequented the ſchools of S. Bourdon, le Sueur, and le Brun; and in his youth went to Rome, where he ſucceſsfully ſtudied and imitated the works of Pouſſin. On his return to Paris, he ſoon became diſtinguiſhed by the merit of his productions. He painted many pieces for the palace of the Thuilleries, and the chateau of Verſailles; and ſo delighted was the king with his works, that he conferred on him a penſion of four thouſand livres. Strutt ſays that he beſtowed too little attention in reviſing his firſt thoughts: yet his compoſitions are not without intelligence; and his figures, eſpecially thoſe of his women and children, poſſeſs a certain degree of delicacy and expreſſion. He was early admitted a member of the royal academy, and at the time of his death held the ſituation of rector.

Loir engraved, with conſiderable freedom and ſome taſte, about a hundred and fifty pieces of different forms, ſome of which are much more finiſhed than the generality of painters' etchings. Of theſe the following are eſteemed the moſt valuable:

A ſeries of twelve plates illuſtrative of the hiſtory of the holy family, in ſmall quarto, and of the upright form. "A Madonna claſping the Infant Saviour." "A Madonna ſitting, with the Infant on her Knees." "A Madonna, with the Infant aſleep," inſcribed "Ego dormio." "A Madonna, with the Infant holding a Croſs in his Hand." "A recumbent Chriſt, embracing the Croſs and Crown of Thorns, with his Eyes turned towards Heaven." "The Judgment of Paris." "Daphne changed into a Laurel." "The filial Piety of Cleobis and Biton," who drew the chariot of their mother Argia to the temple of Juno, of which ſhe was a prieſteſs; the above are all in folio, and the laſt is eſteemed to be, on the whole, the beſt of Loir's performances. Two large landſcapes, lengthways.

Alexis Loir, the younger brother of Nicholas, was born at Paris in 1640, and died in the ſame city in 1713. Young Loir was an excellent deſigner and engraver, though partly educated a goldſmith; his manner was eaſy, vigorous, and expreſſive, and he knew how, to a certain degree, to vary his ſtyle according to the maſters after whom he engraved. He executed ſeveral etchings, but his croſſed hatchings were too ſquare, and his lights too much and too equally covered for this ſpecies of engraving. We add a liſt of the beſt of the works of this artiſt, which are in general of large dimenſions.

"The Education of Mary de Medicis;" after one of the paintings of Rubens in the gallery of the Luxembourg, in folio. "Time diſcovering Truth, and treading Herely under Foot," from the ſame maſter, in folio. "The different Nations of Europe;" after Ch. le Brun, in folio. "The Fall of the rebellious Angels," after the ſame; large and engraved on two plates. "The Maſſacre of the Innocents," after the ſame, and alſo engraved from a motive of convenience to the engraver, on two plates. "A weeping Madonna, with the dead Chriſt on her Knees," after P. Mignard, in folio, a large upright, arched at the top. "The Finding of Moſes," after Pouſſin. "Venus preſenting Arms to Æneas," after the ſame, in folio. "The Adoration of the Kings," after Jouvenot, in folio. "The Preſentation in the Temple," after the ſame, in folio. "A dead Chriſt ſurrounded by many Figures, at the Foot of the Croſs," after the ſame, in folio. "A Madonna with a ſleeping Chriſt," after Nic. Loir, in folio. "A Holy Family," in which the infant Jeſus is ſitting on a croſs, after the ſame, in folio, and of the circular form. "A Holy Family," compriſing four figures, after the ſame, in folio. "A Magdalen at Prayers," after the ſame; a capital piece.

Nicholas Regneſſon was born at Rheims about the year 1625, and died at Paris in 1676. He was the brother-in-law, and according to ſome French writers, the inſtructor, of the celebrated Nanteuil, but he was only five years older, and Strutt with more probability aſſerts that he learned from Nanteuil the art of engraving. Their ſtyles bear conſiderable reſemblance, but the argument which may be derived from the evident vigour of original feeling, is entirely in favour of Nanteuil.

The engravings of Regneſſon are however juſtly held in eſteem. They conſiſt partly of frontiſpieces, and other book-plates, from his own deſigns, but chiefly of portraits on a larger ſcale, and alſo from drawings by himſelf, which were performed in crayons, of which the following will be found moſt worthy of notice:

Anthony Fremin, ſecretary to the queen-mother. Cardinal Julius de Mazarin in an octagonal frame of oak-leaves, dated 1656. A young magiſtrate, dated 1661, all in folio. Francis de Vendoſme, duke of Beaufort, grand admiral of France, after Carelle, in folio; and the princeſs of Conti, a buſt after Beaubrunn, in quarto.

Of his hiſtorical works, thoſe of moſt importance are,

"The Marriage of St. Catherine," round, bordered with oak-leaves, inſcribed Nic. Regneſſon fec. in folio. "The Holy Family," by Regneſſon and Nanteuil, in folio. "A Madonna, with her Eyes raiſed," after Le Brun, in folio. "A Buſt of the Infant Saviour," after the ſame, without the name of the engraver, but which is known to be from the graver of Regneſſon, in folio. "The Deſcent of the Holy Ghoſt," after a painting in the cathedral of Notre Dame, from Blanchard, in folio. "A Holy Family," ſurrounded by a border of roſes and lilies, after N. Coypel, in folio. "A Madonna with the Infant Jeſus and the little St. John," after F. Bourdon, in folio.

Stephen Gantrel was born at Paris in 1626, but the year of his death is not recorded. He publiſhed ſeveral prints, of which the ſubjects are hiſtorical, as alſo a great number of portraits, engraved by himſelf in a tolerably good ſtyle.

We begin our liſt with his hiſtorical works, which are chiefly of the folio ſize.

" The Rod of Moſes changed into a Serpent devouring thoſe of Pharoah's Magicians," after Pouſſin. " The Paſſage of the Red Sea." " The Worſhip of the Golden Calf." " The Deſcent from the Croſs." " St. Francis Xavier reſtoring an Indian to Life;" all after the ſame maſter, and in folio. " St. Gervaiſe, and St. Protais, before the Proconſul," after Le Sueur, a diſtinguiſhed piece. " St. Benedict kneeling," after Ph. de Champagne. " St. Francis in a Trance, upheld by Angels," after Caracci; and a " Buſt of the Saviour," from Le Brun; theſe are alſo in folio, as are the following portraits:

Sebaſtian Piſani, biſhop of Verona, inſcribed Steph. Gantrell ſc. Antoine Bruneau, counſellor-preſident of Tournelle, La Dam pinx. Jean Louis de la Bourdonnaye, count-biſhop of Lyons, Eligius Fontaine pinx. Mathew Poncet de la Riviere, maſter of requeſts, inſcribed Stef. Gantrel ſc. 1681. Louis Berryer, firſt counſellor to the king, almoſt as large as life, dated 1674. Louis XIV., king of France, the head as large as life, and inſcribed Stef. Gantrel fec.

Of the family of the Coypels, and their characters as artiſts, we have already given an account. (See COYPEL.) Noel, the elder, etched a Madonna careſſed by the infant Chriſt, dated 1664; another plate of the ſame ſubject, larger, and " The Holy Family," including St. Joſeph and St. John. But Antony produced a more conſiderable number, which have obtained from Strutt more praiſe than they will probably be found to deſerve. They are however ſought after by ſome connoiſſeurs, and the beſt of them are entitled as follows:

Two portraits of Le Voiſin, who was burnt in the Place de Greve, one large, the other ſmall. A buſt of Democritus, inſcribed A. Coypel pinxit incidit et excudit 1691, in quarto. " The Meeting of Abraham and Melchiſedec," a medallion. " Judith," the plate of which was finiſhed by C. Simoneau, a ſmall upright. " The Baptiſm of Chriſt," inſcribed A. Coypel pinx. et fecit. " An Ecce Homo," alſo finiſhed by C. Simoneau, a ſmall upright. " Chriſt in his Winding Sheet." " A Madonna and Child," an oval. " A Madonna ſuckling the Infant." " A Magdalen periſhing in the Deſert," anonymous. " A St. Cecilia," inſcribed " Cantabo Domino in vita mea." " An Allegory," illuſtrative of the fame of the Dauphin, or the ſycophancy of the times. " The Infant Jupiter confided to the Nymphs." " Cupid conquering Pan," dated 1691, inſcribed A. C. " Bacchus and Ariadne," a large and excellent plate finiſhed by Audran; and " The Triumph of Galatea," another large plate, finiſhed by C. Simoneau.

The etchings of Noel Nicholas Coypel, of which the ſubjects follow, are ſomewhat inferior to thoſe of his elder brother Anthony.

" St. Thereſa ſurrounded by numerous Angels," an oval in quarto. " The Triumph of Amphitrite," in quarto. " A ſleeping Nymph ſurpriſed by a Satyr," in quarto. " A young Woman careſſing a Dove," the plate of which was afterwards finiſhed with the graver by N. Edelinck.

The ſtyle of Charles Antoine Coypel was by far too much made up of the affectation and inſipidity of the old French ſchool, for him to have merited the praiſes which are beſtowed on him by Strutt. Though he had the advantage of being inſtructed by his father Anthony, and of inheriting his court patronage, he laboured both in the arts and belles lettres to little purpoſe. Yet the following engravings by this artiſt cannot properly be omitted in collections of the productions of the French ſchool, *viz.*: Portraits of M. de Maroulles, duke of St. Paul, and François Potet, ovals, in quarto. Portrait of the painter Cigoli, in chiaro-ſcuro. " The Madonna worſhipping the Infant Jeſus while aſleep in his Cradle," an anonymous engraving, in imitation of the ſtyle of Guido. " A Crucifix embraced by Mary Magdalen." Two heads, of which one is the St. Paul from the cartoon of Raphael. A ſtanding figure of Cupid, in folio, one of the beſt of this artiſt's productions, and certainly a work of merit. " Apollo with his Lyre," after Michael Angelo, in folio. " A Shepherd converſing with two Shepherdeſſes." " Two young Girls predicting the Fortune of a Lord." A ſet of three plates of the delights of a French devotee. In the firſt ſhe is repreſented on her knees, in the ſecond returning from church, with her prayer book, and in the third ſcolding her waiting woman. Charles alſo engraved ſome other comic and farcical ſubjects, conſiſting of old maids, cats, coquettes, petit maitres, &c. and, in conjunction with count Caylus, he etched a deſign for a tomb, and ſix or eight caricatures of opera figurantes.

Antoine Bouſonnet Stella, the nephew of Jacques, whom we have already mentioned, was born at Lyons in the year 1630, and died in the ſame city in 1682. He acquired the rudimental principles of his art under his uncle, whoſe ſtyle he ſucceſsfully imitated. While he remained in his native city he executed ſeveral good pictures, and on afterwards repairing to Paris, he acquired ſo much celebrity by his talents, that he was received into the Royal Academy.

The following, among other pieces, were engraven by this artiſt:

" A Landſcape," on one ſide of which is repreſented Tiber with his urn, and the ſhe-wolf that nurſed Remus and Romulus; on the oppoſite ſide appears another river god, and in the middle a view of the city of Rome; a ſmall piece in folio, dated 1654. " Moſes defending the Daughters of Jethro," after Pouſſin, inſcribed Bonnart excud. This appears without the name of the engraver, but Huber aſcribes it to the artiſt now under notice.

Claudine Bouſonnet Stella was born at Lyons A. D. 1634, and died at Paris in 1697. She acquired the elements of painting from her uncle Jaques Stella, but ſhe attached herſelf in preference to engraving, which ſhe executed in a very ſuperior ſtyle.

Strutt ſays of the prints by Claudine, that they " prove the ſtrength of her genius, and the ſoundneſs of her judgment:" that the naked parts of her human figures are exceedingly well drawn, and the characters of her heads finely expreſſed; and Watelet proceeds ſtill further in her praiſe: he ſays, " it muſt be admitted that no one ſeized with ſo much accuracy the true art of Pouſſin; no one has ſucceeded ſo well in indicating the colouring of this maſter, and, in ſhort, on viewing the prints of Claudine, we behold in this reſpect a complete repreſentation of the pictures. She far ſurpaſſed Peſne, and even improved upon Gerard Audran." Such is the encomium of Watelet, but in the opinion of the writer of this article, our countryman Strutt has more juſtly eſtimated this lady's talents. Her merits reſide far leſs in her indications of local colour, than in the drawing, characters, and expreſſions of her heads and hands. In the plate of Moſes ſtriking the rock, particularly, theſe parts are ſo ſuperior to the reſt of the performance, as to beget a ſuſpicion that the draperies and landſcape are the work of ſome inferior hand, and perhaps of her ſiſter Frances. Yet the whole is very well kept together, and a pretty good general tone prevails. Of the engravings by this lady we ſhall notice a 4to. book of paſtorals, engraved on ſeventeen plates, including the title-page, after Jac. Stella A ſeries of fifty plates of children's ſports and ruſtic ſubjects, from the ſame maſter, in folio. " The Myſterious Marriage of St. Catherine,

therine, with the Infant Chriſt," from the ſame, in folio. "Medallion of a Cardinal ſupported by Religion, and ſurrounded by the Virtues," Ant. B. Stella pinx. Cl. Stella ſ. 1678, in folio. "Moſes expoſed on the Nile." Nic. Pouſſin pinx. Cl. Stella ſc. 1672, in two plates, in folio. "Moſes Striking the Rock," Id. pinx. id. ſc. in folio. This piece is eſteemed a chef-d'œuvre of Claudine. "The Crucifixion of our Saviour between the Two Thieves," uſually termed "Le Grand Calvaire," id. pinx. id. ſc. This is another of the beſt works of Claudine. "Peter and John curing a Lame Man in their way to the Temple," Id. pinx. Cl. Stella ſc. dated 1679. "A Holy Family," from the cabinet of the king of France, id. pinx. id. ſc. in folio. "A Holy Family," with ſeveral children carrying flowers, Nic. Pouſſin pinx. Cl. Stella ſc. dated 1661, in folio.

Antoinnette Bouſonnet Stella, ſiſter of Claudine, was born at Lyons about 1635. She enjoyed the ſame inſtruction as her brother and ſiſter, and as an engraver was ſcarcely inferior to either of them. The two following pieces are the only ones executed by this lady, which have been handed down to us; but they are ſufficient to evince that ſhe poſſeſſed very ſuperior talents.

"Remus and Romulus, nurſed by a ſhe-wolf on the Banks of the Tiber," after Antoine Bouſonnet Stella, her brother, in folio. "The Entrance of the Emperor Sigiſmund into Mantua," from a long frieze executed in ſtucco, in the palace del T. after a deſign of Julia Romano.

The Stellas had another brother, named Francis, and, according to Mr. Strutt, a ſiſter, named Francoiſe, who aſſiſted Claudine in executing her plates, and who died in the year 1676.

Louis Ferdinand was born at Paris ſome time about the year 1630, and was the ſon of Ferdinand Elle, who had the honour of inſtructing Pouſſin. Elle had another ſon, of the name of Pierre, who was alſo an engraver, and worked in conjunction with Louis, but why they aſſumed the baptiſmal name of their father, and diſcontinued the ſirname of Elle, does not appear.

Neither of the ſons diſplayed much talent as an engraver, yet Louis attained ſome diſtinction as a painter of portraits, and became a profeſſor in the French Academy.

A drawing-book, entitled "Le Livre Original de la Portraiture, pour la Jeuneſſe, tiré de Bologne et autres bon Peintres, a Paris, 1644," has been aſcribed ſeverally, both to Louis and Pierre, and it is not improbable that they were mutually concerned in producing it. The maſſes of light and ſhade are tolerably well diſpoſed in this work, but the outlines not being correct, it is radically defective. Other engravings by theſe artiſts, are,

The head of a lady, after Van Dyke, in quarto. The portrait of Nicolaus Pouſſin, inſcribed V. E. pinxit, L. Ferdinand fecit, an oval, in ſmall folio. A ſeries of ornaments, in the form of friezes, with genii, intermingled with feſtoons and garlands after L. Teſtelin, ſix plates. L. Ferdinand fec. P. Mariette exc. in quarto. A ſeries of groupes of children, after the ſame; ſix plates, in ſmall folio. St. Potentiana, in a frame, from Correggio, in quarto.

Nicolas Bazin was born at Troyes, in Champagne, about 1636. He was the pupil of Claude Mellan at Paris, where he became a printſeller. He himſelf engraved a great number of pieces, but he alſo employed ſeveral young artiſts to aſſiſt him in his labours. His productions, for the moſt part, conſiſt of portraits and devotional ſubjects, engraved in a ſtiff and dry manner. They are uſually in quarto, inſcribed with the name of Bazin, and the beſt of them are entitled as follow:

"The *true* Portrait of the Virgin, painted by St. Luke." "The Annunciation of the Virgin," in folio. "A Chriſt crowned with Thorns," in folio. "The Criſifixion," in folio. "St. Jerome and St. Peter," a pair, after Lichery. "St. Francis branded," after Baroccio. "St. Iſabella of France, the Founder of the Abbey of Long-champ," after Ph. de Champagne. "St. Anne learning to read from the Holy Virgin," after Le Brun. "St. Mary the Egyptian, and St. Bozime," after the ſame. "A Madonna giving ſuck to the infant Jeſus," after Correggio, copied from the print of Spierre. "A Female in a faſhionable Dreſs, and a Lady of Quality undreſſed to enter the Bath," after Jean Dieu, called St. John, a pair, in folio.

Among the portraits of this artiſt, the following are perhaps the beſt.

Madame Helyot, a celebrated abbeſs, Bazin del. et ſc. 1686. Madame Guyon, the celebrated viſionary. Jean du Houſſay de Challiot, who lived as a hermit during forty-eight years at mount Valerien. Father Emanuel Magnan of Toulouſe, of the order of the Minor Brothers. Father Antoine Verjus, who firſt led the Jeſuit miſſionaries to China, after B. Cary. Father Jean Craſſet, of the fraternity of the Jeſuits, and director of their congregation at Paris, after Mee. St. Francis Xavier, the Jeſuit apoſtle of India. St. Ignatius Loyola, founder of the order of Jeſuits, Louis the Great, on horſeback, N. Bazin ſc. 1682, in folio. Louis, dauphin of France, painted by J. B. Martin, and engraved by N. Bazin, 1686, in folio.

Peter Landry, who was born at Paris in the year 1630, according to Huber, is one of thoſe artiſts who did not enjoy a reputation commenſurate with their merits. He engraved various pieces, both from his own compoſitions, and after thoſe of other artiſts. His portraits are executed with much ſtrength and neatneſs. Strutt, however, is of a different opinion, and calls them "ſtiff and heavy."

The following are a few of his hiſtorical works, which are beſt known, and are all of the folio dimenſions. "St. Jerome." "A Madonna, with the infant Chriſt in his Cradle." "The Samaritan," after Albano. "A large Head of John the Baptiſt," after Caracci.

Of his portraits, we ſhall mention thoſe of Louis XIV. after J. François. Louis de Bourbon, prince of Conti, after Gribelin. Charles de Bourbon, biſhop of Soiſſons, inſcribed Jo. Laniele del Petrus Landry ſc. 1666. Charles Brulart, marquis of Genlis. An anonymous portrait, which is known to be that of count Harcourt, commonly called le Cadet de la Perle; all of which are in folio.

Jean Froſne was born at Paris about the year 1630. He appears to have dedicated his attention ſolely to engraving portraits, in which he imitated, with ſome ſucceſs, the ſtyle of Nanteuil; of theſe portraits forty-three were collected by the abbé Marolles. He was, however, qualified to ſucceed in other departments of his art, as may be ſeen from the ornamental plates which he engraved for the collection of grand views of Sebaſtian de Beaulieu. We may mention the following folio portraits by Froſne, as poſſeſſing much merit in the execution.

Claude Baudry, abbé of the Holy Croſs, after le Bon, dated 1657. Nicholas Dauvet, count Deſmarez, grand falconer of France, after Streton. Louis de Lorrain, duke of Joyeuſe. Henry d'Orleans, duke of Longueville. Nicholas Putier of Blancmeſnil, preſident of the French parliament; and M. Dreux d'Aubray.

But all theſe are engravers of mere mediocrity, compared with Robert Nanteuil, who muſt ever be regarded as one of the wonders of his profeſſion. This admirable artiſt was born at Rheims in the year 1630, and died at Paris in 1678. Being the ſon of a merchant of ſmall fortune, he received a

claſſical

claſſical education, yet during the intervals of literature, found time to cultivate the fine arts alſo; and to mark his decided predilection for that of engraving, he even engraved his theſis in philoſophy. He married at an early age, and on viſiting the French metropolis, he voluntarily abandoned all other purſuits, and devoting himſelf entirely to the art of engraving portraits, became the moſt original, and perhaps, on the whole, the beſt portrait engraver that ever exiſted.

He happily lived in an age when his art was patronized. Louis XIV. being made acquainted with his merit, cauſed him to draw his portrait in crayons, and was ſo pleaſed with the performance, that, according to Strutt, he created purpoſely for Nanteuil, "the place of deſigner and engraver of the cabinet, with the yearly penſion of a thouſand livres, which was confirmed by letters patent," and which our artiſt continued to enjoy with the higheſt reputation to the time of his death.

When the great care and preciſion beſtowed on his engravings are conſidered, and when is conſidered alſo the ſhort period of his life, and that the charms of his converſation occaſioned his ſociety to be courted by men of the firſt rank in the ſtate, as well as thoſe of the firſt genius in fine art, it may juſtly excite ſurpriſe that he ſhould have produced no fewer than two hundred and eighty plates, ſome few of which are hiſtorical ſubjects, but moſt of them portraits, of which ſome are as large as life, and were engraven from nature, through the medium of crayon pictures executed by the engraver himſelf. We have mentioned two hundred and eighty, becauſe that number were found in the collection of Mariette; but it is not known that Mariette had collected the whole of his works.

Nanteuil appears to have underſtood the "human face divine" better than any of his predeceſſors. He drew correctly; even his ſlighteſt prints manifeſt the hand and mind of a maſter; and in his more highly finiſhed works, the perfect keeping of his heads, as they appear in the fine impreſſions, is admirable. Strutt argues that "from the great difference we perceive in the characters of his heads, we may conclude they were faithful copies of Nature," and when this is combined with the ſtill ſtronger preſumption ariſing from homogeneouſneſs of parts, it will probably be received as the ſtrongeſt internal evidence, and the beſt aſſurance that can now be obtained, of the reſemblance of Nanteuil's portraits to their reſpective originals.

His ſtyle of engraving he appears to have varied on principle, at different periods of his life; at firſt, probably, as his feelings, and afterwards as his judgment, directed. It was Nanteuil who firſt explored the unknown practicabilities of this department of art, and invented modes of combining lines with ſtippling, ſo as to expreſs the firm ſoftneſs of fleſh whether in light, ſhade, or middle tint: hair, with all its lightneſs of forms, its native gloſs, and its varieties of flow and colour: ermine he alſo taught his ſucceſſors to characteriſe, and the peculiar textures of the various articles of dreſs. The engravers who will compare Nanteuil's works with each other, may trace in them what ought to be called a courſe of the experimental philoſophy of portrait engraving, over which genius preſided. He appears at firſt, like Mellan, to have employed ſingle courſes of lines, as may be ſeen in his portrait of Louis Heſſelin: in the fleſh of that of Chriſtina of Sweden, he employed ſtippling alone; while in that of the preſident Mole, he employed only unbroken lines. It would appear that he was now analyſing his art, and meaſuring his own powers againſt its difficulties, and that in his ſubſequent works, he combined the elements which he now aſcertained, of ſoft, firm, clear, rich, mellow, and characteriſtic ſurface, as occaſion admitted or required. His moſt frequent and moſt admired practice was, to ſtipple the lights and half tints of his faces, and employ croſs hatchings, ſometimes with interwork, for the ſhadows, inſenſibly blending his carnation tints, (as a painter would ſay,) except where abruptneſs was demanded by the ſubject; and over all, unſwayed by the ornamental tendency in that luxurious age of the art of his country, he threw the ineffable charm of ſimplicity.

The more rare and beautiful of the works of this diſtinguiſhed artiſt are as follow:

A folio plate of "The Holy Family," which, as has been mentioned, he engraved for the theſis of philoſophy which he ſupported at Rheims. From the date of this print, 1645, it appears that it was engraved at the early age of fifteen. An allegorical print of Time diſplaying the buſt of Louis XIV., while Hiſtory records his exploits, in folio. "A Muſe or Genius, and an Eagle ſupporting a Crown and various Heraldry, with the Motto, "Fides," in folio. "Cardinal Mazarin, ſeated in the midſt of a Gallery of Buſts and Statues, conſulting ſome Maps which are diſplayed before him," after F. Chauveau, in folio. "Chancellor Seguier, ſurrounded with the Attributes of Juſtice, and of the Arts and Sciences," after Le Brun, in folio. A large head of Chriſt, after Guido, dated 1653, in folio. "A Siſter of the Order of Mercy," a buſt, dated 1664, after the ſame, in folio.

Portraits of the potentates of Europe, of the folio ſize, (N. B. when no painter's name is mentioned, they are engraved from the crayon pictures of Nanteuil himſelf,) Anne, Infanta of Spain, queen of France, and mother of Louis XIV. R. Nanteuil pinx. et ſculp. 1666, very large. Eight different portraits of Louis XIV. engraved in the various modes which our artiſt from time to time invented or adopted.

Louis dauphin, ſon of Louis XIV. 1677. Louis prince of Condé, 1662. Henry Julius Bourbon, duke d'Anguin, after P. Mignard 1662. Chriſtina queen of Sweden, after S. Bourdon, 1654, ſmall, and in the peculiar ſtyle which has been already mentioned.

Louiſa-Maria, queen of Poland and Sweden, after Juſte, 1653. Charles Emmanuel, duke of Savoy, 1668. Maria Jean-Baptiſte, ducheſs of Savoy, and Regent, after Laur du Sour, 1678. Charles, duke of Lorrain, 1660. John-Frederic, duke of Brunſwick Lunenburg, after Michelin, 1674. Charles II. duke of Mantua, 1652. William Egon, prince of Fuſtenburg, cardinal and biſhop of Straſburg, 1671.

The following portraits of illuſtrious ſtateſmen, warriors, and men of letters, are alſo in folio, and are arranged in alphabetical order.

N. duke d'Albret, 1649; this is extremely ſcarce. Jaques Amelot, firſt preſident of the court of aids, 1655. Louis Dony d'Attichy, biſhop of Autun, 1663. Henry de Baradat, biſhop of Noyon, Velut pinx. with the biſhop's arms, but without date or ſignature. Antoine Barberini, cardinal and archbiſhop of Rheims, 1663. Emmanuel Philibert Beaumanoir de Lavardin, biſhop of Mans, after Champagne. Pomponne de Bellievre, preſident of the parliament. Francis Blanchard, abbé of St. Genevieve, 1673. Francis Blondeau, preſident of the chamber of accounts, 1653. Antoine Bachart, abbé of Champigny. Peter de Bonſy, archbiſhop of Narbonne, 1678. Jacque Benigne Boſſuet, biſhop of Meaux, 1674. Louis de Boucheret, chancellor of France, 1676. Emmanuel Theodore de la Tour of l'Avergne, duke of Bouillon and a cardinal, 1670. Leon le Bouthillier, count of Chavigny, miniſter of ſtate after Champagne, 1652. Anne Philipeaux Villeſavin,

ſavin, widow of Leon le Bouthillier, 1656. Henry-Auguſtus de Lomènie, count de Brienne, ſecretary of ſtate, 1660. Jean le Camus, maſter of requeſts, 1674. Jaques, marquis de Caſteinau, mareſchal of France, 1658. Marin Careau de la chambre, phyſician to the king. Guy Chamillard, maſter of requeſts, 1664. Jean Chapelin, counſellor of ſtate, 1655. Charles d'Ailly, duke de Chaulnes, governor of Brittany, 1676. Francis de Clermont, biſhop of Noyon, 1655. Peter de Cambert de Coiſlin, biſhop, and afterwards cardinal of Orleans, 1666. Peter Armand du Cambout de Coiſlin, abbé of St. Gildas, 1658. Jaques-Nicolas Colbert, abbé of Becq, and afterwards archbiſhop of Rouen 1670. Jean-Baptiſt Colbert, miniſter of ſtate, 1676. Francis de Bonne, duke de Crequy des Leſdiguieres, lieutenant-general, 1662. Dreux Daubray, count d'Offremont, counſellor of ſtate, 1658. Peter Payen Deſlandes, 1659. Jean Dorieu, preſident of aids, 1660. Francis-Antoine Dulieu maſter of the chamber of accounts, 1667. John Evelyn, eſq. author of "Sylva Sylvarum; a treatiſe on Calcography," &c. Ferdinand de Foix de la Valette, duke of Eſpernon, colonel-general, 1650. Ceſar d'Etree, biſhop of London, then cardinal, 1660. Andre le Fébre d'Ormeſſon, counſellor of ſtate, 1654. Gaſpar de Fieubet, counſellor of the parliament of Toulouſe. Nicolas Fouquet, ſuperintendant of the finances, 1661. Pierre Gaſſendi the philoſopher, 1658. Melchior de Gillier, counſellor of the king, 1652, and madame de Gillier his wife, a companion print. Francis Guenault phyſician, 1664. Henry de Guenegand, marquis de Plancy, ſecretary of ſtate after Champagne. Francis de Harlay de Chauvallon, archbiſhop of Paris, 1675. Louis Hepelin, counſellor of ſtate, engraved in the ſtyle of Mellan, 1660. William de Lamoignon, marquis de Baville, preſident of the parliament, 1659. Another plate of the ſame nobleman, dated 1676. Peter Jeannen, firſt preſident of the parliament. Dominick de Ligny, abbé and afterwards biſhop of Meaux, 1654. René de Longueil, marquis de Maiſon, miniſter of ſtate and preſident of the parliament, 1660. Henry d'Orleans, duke de Longueville, after Champagne. Francis Lotin de Charny, preſident of the parliament, 1657. Jean Loret of Carenton in Lower Normandy, 1658, ſmall folio. Francis Mallier, biſhop of Troyes, after Velut. Leonor de Matignon, biſhop of Liſieux, after P. Antonin. Cardinal Julius Mazarin, with a back-ground of ſtars, 1655. The ſame ſubject, engraved in the taſte of Mellan. Jean de Maupeoux, biſhop and count of Cavaillon, 1671. Charles de la Porte, duke de la Mellerage, mareſchal of France, after Juſte, 1662. Jean de Megrins, preſident of the parliament of Toulouſe, after Daret, 1652. Jean-Antoine de Meſme, count d'Avaux, 1662. Edward Mole, preſident of the parliament, 1653, (noticed in our biography of the artiſt.) Henry de Lorraine, marquis of Mony, 1651. Francis de Neſmond, biſhop of Bayeux, 1663. Nicholas Potier de Novion, firſt preſident of the parliament, 1656. Charles Paris d'Orleans, count de St. Paul, after Ferdinand, 1660. Hardouin de Perefixe de Beaumont, archbiſhop of Paris, 1662. Louis Phelipeaux de la Vrilliere, ſecretary of ſtate, 1662. Simon Arnauld de Pomponne, ſecretary of ſtate, 1657. Jean Francis Paul de Gondy, cardinal de Retz, 1650. Armand-Jean du Pleſſis, cardinal de Richelieu, after Champagne, 1657. Jean Francis Sarraſin, counſellor to the king, 1656, in 4to. Henri de Savoye d'Aumale, archbiſhop of Rheims, 1651. Pierre Seguier, chancellor of France, after le Brun, 1656. Pierre Seguier, marquis de St. Briſſen, mayor of Paris, 1659. Francis Servien, biſhop of Bayeux, after Champagne, 1656. Jean Baptiſte van Steenberghen, termed "the Dutch advocate," after du Chaſtel, 1668. This is eſteemed a chef-d'œuvre of Nanteuil. Denis Talon, advocate-general. Charles-Maurice le Tellier, archbiſhop of Rheims, 1663. Michel le Tellier, chancellor of France, 1662. Michel le Tellier, marquis de Louvois, ſecretary of ſtate, 1677. Henri de la Tour d'Auvergne, viſcount de Turenne, 1665. Francis de la Mothe le Vayer, 1661.

Germain Audran was born at Lyons A. D. 1631. He acquired the rudiments of his art in his natal city, and under the ſanction of his father Claude, of whom we have already ſpoken; after which he repaired to Paris, where he purſued his ſtudies under the direction of his uncle Karle. He afterward returned to Lyons, where he engraved and publiſhed a conſiderable number of prints, conſiſting of ornaments, ceilings, vaſes, &c. and a few portraits, which Strutt ſays do honour to his graver. He was made a member, and afterwards choſen profeſſor of the academy eſtabliſhed at Lyons, in which city he died in the year 1710, leaving four ſons who were all artiſts.

His beſt portraits are thoſe of Charles Emanuel II. and Frances d'Orleans, in the ſame oval, after Caravaglia; cardinal Richelieu in an oval, ornamented by laurels, and Theophilus Reynard, dated 1663, in folio.

The chief of his other engravings are a ſet of ſix plates of deſigns for ceilings, after George Charmetin; another ſet of ſix ornamented vaſes after N. Robert; a book of friezes, after la Fage, a large book of Italian views after Funcus, ſix landſcapes from le Gaſpie, and a ſet of thirty deſigns for fountains and maritime friezes, after le Brun.

Of Claude Audran, the ſecond of that name, and whoſe virtues, ſays the abbé Fontenai, were as praiſe-worthy as his talents were great, no engravings have been mentioned by his biographers, and none have been ſeen by the preſent writer, though Heinnekin ſpeaks of him as having been an engraver. He was born in the year 1639, and died at Paris in 1684.

Girard or Gerard Audran is at once the moſt celebrated of his family, and the boaſt of his country and his profeſſion. Though he did not invent the art of mingling etching with the work of the graver, he improved ſo much upon what had previouſly been done in this way, and ſo out-ſtripped his competitors in the race, that it may eaſily be believed he would have invented this art, had it not previouſly exiſted. Untrammelled, or not ſubmitting to ſuch trammels as the mechanical part of the art of engraving impoſed on his contemporaries, he looked with bolder viſion into that of painting, or rather he looked both abroad into the phyſical world, and into the reſources of his own vigorous mind, for the materials of honeſt fame, and was guided alone by the light which they mutually reflected on each other.

That he was thoroughly verſed in the academical part, or grammar, of his art, may be ſeen in his work, entitled "Les proportions du corps humain ſur les plus belles ſtatues de l'antiquité, à Paris, chez Audran Graveur du Roi," a folio work publiſhed in 1682; and it may be heard in the liberal encomium of Le Brun, that the engraver had in this reſpect ſurpaſſed the painter. In juſtice to both theſe diſtinguiſhed artiſts, who ſeemed born for each other, this declaration of Le Brun ſhould not be paſſed in ſilence.

So broad, original, and comprehenſive was the ſtyle of our artiſt, that Watelet has emphatically ſaid of him, "he *painted* with the etching-needle and graver," and ſo ſurpaſſing thoſe of all other artiſts are his engravings after Le Brun, Pouſſin, and Le Sueur, that it may be aſſerted of Audran, almoſt without an hyperbole, that he poſſeſſed the power of animating their forms with his own ſoul, as was fabled of the oriental philoſopher of old.

Thus

Thus much it has been thought neceſſary to ſay in this place, in addition to what the reader will find under the article AUDRAN GIRARD, reſpecting this truly great artiſt. The collector may not be diſpleaſed to find here a more copious liſt of his principal engravings, than we were at that time able to furniſh, beginning with the portraits and other pieces which he engraved after his own pictures and drawings.

Pope Clement IX. Andreas Argolus, S. Marci Eques, in quarto. Samuel de Sorbiere, (a man of letters,) engraven at Rome in 1667. Henri Arnaud, biſhop of Angier. Father Benedict Langeois, a capuchin. Francis du Queſnoy, ſculptor, commonly ſtyled Fiamingo. "St. Paul preaching at Athens," a vignette, with the inſcription :—"Non enim ſumus adulterantes, &c." "Minerva" and "Abundance," two ſtanding figures, and on high two genii holding a ſcroll, with the words "Louis le Grand," a frontiſpiece, in ſmall folio, dated 1680.

After Italian maſters, we find the following ſubjects in folio, and for the moſt part very large; "The Filial Piety of Æneas," after a picture of Dominichino, formerly in the cabinet of the French king, performed with the graver only, and ſomewhat harſh in its chiaro-ſcuro. "The Myſtery of the Roſary," after a painting of Dominichino at St. John du Mont de Bologne. "The Martyrdom of St. Agnes," after a painting of the ſame maſter at Bologna, in the church of that ſaint. "The Temptation of St. Jerome," after the ſame. "The Four Angles of the Church of St. Charles de Catenari, repreſenting Juſtice, Temperance, Prudence and Courage," after the ſame, in four plates, engraven at Rome in 1675. "The Gift of Tongues," and "St. Paul preaching at Athens," after Pietro da Cortona, two friezes on the ſame plate. The gallery painted at Rome in the palace of Pamphili, by the ſame maſter, repreſenting the hiſtory of Æneas, engraven on ſixteen plates, and forming a ſeries. The gallery painted by the ſame artiſt, at the palace of the marquis Sachetti, and engraven at Rome in 1668 in three large plates, repreſenting the triumphs of David over Goliah and the Philiſtines. "The Death of St. Francis," after Annibal Carracci. "The Martyrdom of St. Sebaſtian," after a painting of Carracci formerly in the poſſeſſion of the French king. "The Temptation of St. Anthony," painted for the Borgheſe gallery by Annibal Carracci. "Ulyſſes diſcovering Achilles in Diſguiſe," after the ſame. "St. Hyacinthe," after Guerchino, ſmall. "A Magdalen," after Guido. "St. Peter walking on the Sea," after Lanfranc. "The Nativity of our Saviour," a ſmall piece, engraven after a deſign of Palma the younger, without the name of the engraver. Thirteen plates of arabeſque figures, painted by Raphael in one of the halls of the Vatican. A ſet of fifteen plates from Raphael's Cupid and Pſyche, dedicated to Le Brun. "God ſpeaking to Moſes from the Burning Buſh," after the ſame. "Paul and Barnabus at Lyſtra," after the ſame. "St. Paul ſcourged by Demons," a ſmall piece, known under this title, though in fact it repreſents "St. Ignatius tormented by Devils during his Slumber." It is engraven after a deſign of Rubens, but falſely attributed to Raphael on the plate. "Jeſus Chriſt delivering the Keys to St. Peter on taking leave of the aſſembled Apoſtles," R. V. inv. G. Au. ſc. "The Death of Ananias," after Raphael. "The Landing of the Saracens at the Port of Oſtia;" after a deſign of Raphael, an anonymous engraving, but known to be from the hand of Audran. "A recumbent Silenus, pouring forth Wine," after Julio Romano. "Dejanira carried away by the Centaur Neſſus," after the ſame, in quarto. "The Clemency of Scipio," another anonymous folio engraving, after Raphael. "The Rape of Ganymede," an octagonal print from a painting by Titian on the cieling of the gallery of antique ſtatues at Venice.

Hiſtoric and allegoric ſubjects after French maſters, beginning with Pouſſin. "St. John baptizing his Proſelytes in the River Jordan," a finely executed engraving, on two plates. "The Woman taken in Adultery." A pair of large and admirable engravings of "The Preſervation of Pyrrhus," and "The Reſentment of Coriolanus appeaſed by his Family," each engraved on two plates. "Camillus delivering up the Schoolmaſter to his Scholars," "The Vengeance of Armida," in which plate Gerard was aſſiſted by his nephews Benoit and John Audran. "St. Franciſco kneeling before the Virgin Mary," who is holding arrows. A pair from Ovid's Metamorphoſes of "Daphne transformed into a Laurel," and "Narciſſus to a Daffodil." "The Empire of Flora," or the metamorphoſes of heroes into flowers. "The Plague of Rome," from a large picture which Pouſſin painted from a deſign of Le Main, and which Audran engraved in conjunction with Baronius. "Time and Truth," from a cieling in the hotel de Richelieu, of which plate, the impreſſions before the drapery was engraved over the figure of truth are very rare.

The above are all after Pouſſin: from P. Mignard he has engraven "The Plague of Egina," commonly termed "The Peſt." (In the early impreſſions of this plate, the figure in the clouds is evidently Juno, attended by her peacock; in the latter impreſſions, the peacock is eraſed, and the wings of an angel are added to the figure of the goddeſs. "Chriſt bearing his Croſs," from an original in the king of France's collection. The cieling of the leſſer gallery of Verſailles, engraved on three plates, of which the ſubjects are "Apollo and the Muſes," "Foreſight and Secrecy," and "Vigilance and Alacrity." Six large plates forming a ſet from the cieling of the Val de Grace, containing upwards of two hundred figures, and repreſenting the felicity of the bleſſed.

From the pictures of Le Sueur he has engraved the Martyrdom of St. Gervais and St. Protais; and on another plate, arched at the top, that of St. Laurence, in folio; and in quarto, "Aurora bringing forth the Horſes of Phœbus." "Time aſſiſted by Love and Truth diſpelling the Clouds of Ignorance," a circle, after L. Teſtelin, folio. "The Army of Pharaoh ſwallowed up in the Red Sea," after Fr. Verdier, in folio. "The Flight into Egypt," after the ſame, in folio. "Battle with the Saracens," after le Bourguignon, in folio. "The Surrender of the City of Damietta," in folio. "The Deciſion of Solomon," after Ant. Coypel, in folio. "The Deluge," after La Fage, in folio. "The Paſſage of the Red Sea," after the ſame. "The Rape of Proſerpine," after the group in the garden of Verſailles, by Gerardon, in folio. "God ſpeaking to Moſes from the Burning Buſh," after Le Brun, in folio. "The Gift of Tongues," after the ſame painter, wherein he has introduced his own portrait. "The Martyrdom of St. Stephen," after a painting by the ſame maſter in the church of Notre-Dame, in folio. "The Triumphal Entrance of Conſtantine the Great into Rome," after the ſame. "The Cieling of the Chapel de Saulx," repreſenting the fulfilment of the ancient law by the new, after Le Brun, in ſix large plates, dated 1681, and remarkable for a ſuperior diſplay of character, expreſſion, and fine drawing. The cieling of the pavillon at Saulx, known under the name of the Pavillion of Aurora. In this work Le Brun repreſents the riſing of the ſun, and the four ſeaſons; engraved on four large plates, and inſcribed to Louis XIV. Four very large engravings from Le Brun's battles of Alexander the Great, of which

which the ſubjects are, "The Paſſage of the Granicus," "The Battle of Arbela, and Defeat of Darius," "The Reception of Porus," and "The Triumphal Entry of Alexander into Babylon;" from the largeneſs of their dimenſions, the artiſt has thought it neceſſary, or found it moſt convenient, to engrave each of theſe ſubjects on four plates, from which the impreſſions are afterwards paſted together. They are at once the largeſt and beſt of hiſtorical engravings, and conſtitute the triumphal entry of that art into Europe.

Of Benoit Audran the nephew of Girard, having already given a biographical ſketch, (ſee AUDRAN, BENOIT,) it remains only to add the liſt of his beſt engravings. We begin with the hiſtorical ſubjects, which are of the folio ſize.

"The Baptiſm of Jeſus Chriſt," after a painting of Albano in the Luxembourg. "The Rape of Dejanira," after Guido. "David beheading Goliah," after a painting (formerly in the cabinet of the French king,) by Michael Angelo, painted on the two ſides of a ſlate, and each repreſenting the ſame ſubject differently treated, engraved on two plates in the years 1716 and 1717, by the two brothers, B. and I. Audran, in folio. "A Gypſey telling Fortunes," after the ſame maſter, in the collection of Crozat. "Lot and his Daughters," after Paul Veroneſe, in the collection of Crozat. "Diſguſt," after the ſame maſter, the original of which was in the Palais Royal.

The following are after pictures by Le Brun: "Moſes defending the Daughters of Jethro," a large piece engraven by John and Benedict Audran in conjunction. "The betrothing of Moſes and Zipporah," companion to the preceding, wholly engraven by Benedict. "The Brazen Serpent raiſed by Moſes in the Deſert." "The Purification of the Virgin, or Simeon in the Temple," a piece marked Audran fec. et exc. "Jeſus Chriſt taken from the Croſs," after a painting in the Luxembourg. "Deſcent from the Croſs," after a painting in the Louvre, dedicated to cardinal de Noailles. "Holland accepting Peace," after a painting in the gallery of Verſailles. "The Baptiſm of Jeſus Chriſt," after P. Mignard. "The Pleaſures of Horticulture," after the ſame maſter, two large friezes engraven by Benedict and John Audran. "Our Saviour at the Houſe of Martha and Mary," after Le Sueur, a large plate, dated 1690. "St. Paul preaching at Epheſus," after the ſame. "Alexander during his Sickneſs taking the Potion preſented to him by his Phyſician," a circular print, after the ſame maſter, from a painting in the Palais Royal, engraven 1711, and eſteemed one of the beſt works of Benoit. "The Accouchement of Mary de Medicis," and "The Exchange of Two Queens," two beautiful engravings from the gallery of Rubens in the Luxembourg. The twelve months of the year, on ſix folio plates, forming a ſet, from paintings by Cl. Audran the younger.

His principal portraits are as follow; Benedict or Benoit Audran, engraver to the king, painted by J. Vivien, and engraven by himſelf, in octavo. Louis Thomas de la Valette, general of the oratory, inſcribed B. Audran fecit ad vivum, in folio. Renaud of the oratory, after Bonnet, in folio. Charles le Gout, archbiſhop of Narbonne, after Bon of Boulogne, an oval, engraven in 1708. John-Baptiſte Colbert, after Cl. le Fevre, an oval, with acceſſaries. Joſeph-Clement, elector of Cologne, after J. Vivien, in folio. Maximilian-Emanuel, elector of Bavaria, marked J. Vivien pinx. Il ſe vend le dit Sieur, in folio. Henry de Beringhen, firſt equerry to the king, marked Nanteuil del. 1663. Bened. Audran ſc. 1710, in folio. Samuel Friſching, general of the Swiſs. J. Huber pinx. Bened. Audran ſc. Pariſiis 1713, in folio. John Frederic de Willading, conſul of the republic of Berne, 1718. J. Huber pinx. B. Audran ſc. in folio. The equeſtrian ſtatue of Louis XIV. erected at Lyons, after Desjardins, conjointly engraven by B. and J. Audran, in folio.

John Audran, the younger brother of Benoit, having diſtinguiſhed himſelf, as has already been obſerved, at the early age of twenty years, and continuing to engrave till he was eighty, produced a conſiderable number of prints which are highly eſteemed. To the liſt of his engravings, which the reader will find under the article AUDRAN, JOHN, we are now enabled to add the following, beginning with the religious ſubjects and thoſe from claſſic hiſtory, which are moſtly of the folio ſize.

"Jeſus Chriſt preaching on ſhipboard," after Raphael. "A Landſcape," in which the infant Jeſus is repreſented in a recumbent poſture, contemplating a croſs, which is held by three angels in the clouds, after Albano. "The Nativity," after P. da Cortona, an oval. "The Good Samaritan," after Annibal Carracci, round. "Saint John adminiſtering the Sacrament to the Virgin," after L. Carracci. "Jeſus on the Mount of Olives," after Dominichino. "St. Andrew adoring the Croſs on which he was to ſuffer Martyrdom," after Guido. "The Martyrdom of St. Peter," after Guido, erroneouſly inſcribed with the name of Dominichino. "St. Paul preaching at Athens," after Ciro Ferri, a ſmall piece in the form of a frieze. "Galatea on the Waters," after C. Maratti, a very beautiful piece, in folio. "The Miracle of the Loaves and Fiſhes," after Claude Audran, in folio. "Jacob complaining to Laban," and "The Reſurrection," both after Coypel, the latter of which is eſteemed amongſt the French, one of the moſt diſtinguiſhed works of that painter. "The Elevation of the Croſs," and "The Crucifixion," both after Vandyke. "The French Parnaſſus of Titon du Tillet," a very large plate, of which the original is executed in bronze. "Acis and Galatea," with Polyphemus on his rock, after F. Marot. "Venus irritated againſt Pſyche," and "Pſyche conſoled by Cupid," both after Nattier. A landſcape after Pouſſin, in which is introduced St. John, the two Maries, Nicodemus, and two angels weeping over the body of Jeſus Chriſt. "The Rape of the Sabines," after the ſame maſter, eſteemed the beſt of the engravings of Audran, and a very ſucceſsful tranſlation of the original picture. "Andromache flying to the Aid of her Son," after L. Silveſtre, and three mixtures of fact and allegory, after Rubens, *viz.* "Henry IV. deliberating on his future Marriage." "The ſame Monarch preparing for the War in Germany," and "The Coronation of the Queen."

The following are portraits, and are all of the folio ſize. Louis XV. on foot, inſcribed Gobert pinx. Audran ſc. Anonymous portrait of the prince with a page, after Vivien. Clement Auguſtus, prince of Bavaria, after the ſame. Jean-Baptiſte Colbert, marquis de Torcy, without his name, after Largilliere, in an oval. Duke of Autin, alſo in an oval. The abbe Victor-Marie d'Etrees, after Largilliere. Cardinal Pierre Ottoboni, after Le Treviſan. Fenelon, archbiſhop of Cambray, after Vivien. Pierre Gillet, after Tortebat. Francis-Robert Secouſſe, doctor of the Sorbonne, ſeated in an arm chair, after Rigaud. Peter-Paul Rubens, after Van Dyke. Noel Coypel, painter in ordinary to the king, after himſelf, and Anthony Coyſevox, ſculptor in ordinary to the king, after H. Rigaud. The two latter were engraven at the time of our artiſt's reception into the Royal Academy, (namely in the year 1703,) and, either on account of their merits or their ſubjects, were the means of that reception.

John Baron, or Baronius, alſo called the *Taloſano*, from the

the place of his nativity, was born at Toulouſe in the year 1631, but ſettled at Rome early in life, where he engraved and publiſhed almoſt the whole of his works. He executed his plates entirely with the graver, in a ſervile, dry manner, neat indeed, but exceedingly defective in drawing, expreſſion, and effect. Yet he had the inſenſibility to attempt great things, of which the following are the ſubjects of a few:

"The Martyrdom of St. Stephen," and that of "St. Andrew," a pair of folio prints, after Nicolo del Abbate. "St. Peter," and "St. Paul," after A. Carracci, a plate in which the heads and hands are engraven by Bloemart. "A Madonna in the act of Adoration," from Guido, in 4to. and another from Bernini. "St. Romualdo," founder of the Camaldales, in which ſeveral eccleſiaſtics are introduced, aſcending to heaven, an upright folio, after Andrea Sacchi. A ſet of twelve plates forming an elementary drawing book, after P. Ferrerio, in folio, and the "Plague of the Philiſtines, with the fallen Idol Dagon," a folio plate after Pouſſin.

But we are chiefly indebted to Baronius for the following portraits, which are of the folio ſize. John de Plantevit de la Pauſe, biſhop of Loudon. Cardinal Aquaviva. Leonardo Alberti, architect. Vito de Bramante, architect. Giovani Franceſco Ruſtici, ſculptor. Marc Antonio Raimondi, engraver. Raphael d'Urbino, painter. Leonardo da Vinci, painter, and others of diſtinguiſhed artiſts, amounting in the whole to fifty.

Charles Mace has been frequently confounded with F. B. Maſſe, the miniature painter. He was employed by M. Jabach, to copy drawings in his poſſeſſion, and to etch the mafterward; and the following hiſtorical landſcapes, after Caſtiglione, are from his hand.

"The Angel commanding Noah to ſtore the Ark with Animals." "Abraham and Sarah on their Way to Egypt." "The Bleſſing of Abraham." "Abraham taking leave of Hagar." "Rebecca departing for Meſopotamia." "Jacob returning to his Father's Houſe." "Rachael returning from Meſopotamia." "Jacob ſending Preſents to his Brother Eſau." "Moſes expoſed on the Nile." "Moſes departing with his Wife and Children for Egypt." The "Nativity," and the "Crucifixion."

The time of the birth of John Picart, who flouriſhed about the middle of the ſeventeenth century, has not been mentioned. He is believed to have been a native of Paris, and to have reſided chiefly in that city; but to have ſtudied engraving under Criſpin de Paſſe. He engraved ſeveral portraits, among which are thoſe of Edward, infant of Portugal, in a ſmall upright oval, with emblems; and a whole length of Eraſmus ſtanding in a niche, beſide other frontiſpieces for books; but his merit is too inconſiderable to deſerve further notice here.

Etienne, or Stephen Picart, is preſumed by Strutt to have been related to John, and to have aſſumed the appellation of "La Romain," (the Roman,) that his works might not be confounded with thoſe of his relation; but from this miſtake his ſuperiority as an artiſt ſufficiently protected him, nor need he, nor would he, with the conſciouſneſs of this ſuperiority, have aſſumed a ſir-name to mark it. A more reaſonable ſuppoſition is, that he choſe to be called Picart the Roman, from a vanity of telling the world that he had ſtudied at Rome. He was born at Paris A. D. 1631, and after reſiding ſome years in Rome returned to his native city, where he became a member of the French academy, and obtained the title of engraver to the king. He died at Amſterdam, (whither he had retired with his ſons,) at the advanced age of ninety.

According to Watelet, Picart executed ſome plates in which etching predominates; but his principal works are performed with the graver only, in a ſtyle ſomewhat reſembling that of Fr. de Poilly, though with inferior ability; yet it is worthy of remark, that ſome paſſages in his works are very ſuperior to the reſt, as for example, the boy who ſtands in the left-hand corner of his "Peſtilence among the Philiſtines," after Pouſſin, and the livid female who lies dead toward the middle of the fore-ground, and whom the child would ſuck, are ſuperior to the tenor of the plate, though it be reckoned among the very beſt of his engravings. The cold lividneſs, which is properly ſpread over the boſom of this dead mother, pervades his ſtyle; his heads in general are thoſe of Pouſſin vulgarized, his extremities are not marked with feeling, and his chiaro-ſcuro is deficient in harmony.

Of the numerous engravings of S. Picart, it may ſuffice to mention the following, which are all in folio.

"An Ecce Homo," accompanied by three Angels, after C. Albano. "The Nativity of the Virgin," after Guido, dedicated to Le Brun. "The Nuptials of St. Catherine," after Correggio. A pair from the ſame painter, of "Heroic Virtue triumphing over Vice," and "Man delivered up to the Pleaſures of Senſe," dated in 1676. Another pair, of "St. Cecilia playing on the Baſs-Viol," and a "Concert of Muſic," after Dominichino, in folio. "A Holy Family," known under the name of "Silence," after Carracci, which has ſince been put to ſhame by the beautiful and maſterly engraving of the ſame ſubject, from the hand of Bartolozzi. "The Holy Family," after a grand compoſition of the elder Palma. "The Separation of St. Peter and St. Paul," after J. Lanfranc. "The Plague of the Philiſtines, and the Overthrow of the Idol of Dagon," after Pouſſin. "Jeſus curing the Blind, on leaving Jericho," after the ſame, inſcribed Picart, (le Romain,) exc. "The Adoration of the Shepherds," after the ſame. "St. Paul cauſing the Books of the Epheſians to be burnt," after le Sueur. "The Martyrdom of St. Gervais, and St. Protais," after the ſame. "The Martyrdom of St. Andrew, and that of St. Stephen," after Le Brun. "The Adoration of the Kings," after Guil. Courtois. "A Madonna, with the infant Jeſus on her Knees," after Noel Coypel. "St. Anthony of Padua, adoring the infant Jeſus," after Vandyke.

The beſt portraits engraved by this artiſt are as follow: Jean-Francois, Paul Gendy, cardinal of Retz, in 4to. A piece executed in the ſtyle of Mellan, and from Picart's own drawing. A buſt of cardinal Fachenettus, after J. M. Morand, in 4to. P. Lucas Waddingus, miniſter-general of the order of St. Francis, after Carlo Maratti. Melchiſedech de Thevenot, a famous traveller, in the oriental coſtume. F. Chauveau del. in folio. Francis Tillemont, abbé of Valchretien, R. Nanteuil del. in folio. Andrew Hameau, doctor of the Sorbonne, Ant. Paillet pinx. in folio. Nicholas Pavillon, biſhop of Aleth. Stef. Picart fecit, in folio. Nicholas Choart de Buſanval, biſhop of Beauvais, inſcribed Stephanus Picart Romanus, fec. et exc. The preſident Claude de Brion, after A. Paillet, in folio, Pierre Loiſel, doctor of the Sorbonne, after F. le Maire, Jean Michel Cigula, a prince of the Ottoman empire, who was converted to the Chriſtian faith, and Frances Athenais de Rochechouart, marchioneſs of Monteſpan.

Bernard Picart, the ſon of Stephen, was born at Paris in the year 1663. He ſtudied under his father, and being admitted to draw from the life at the French Academy at the age of ſixteen, he two years afterwards gained the prize. It is ſaid that he took up the graver with reluctance: he contin-

nued, however, both to design and engrave at Paris until the year 1710, when he accompanied his father to Amsterdam, with some intention of proceeding to Sweden; but certain offers that were made him by the Dutch booksellers induced him to alter his mind, and he continued to reside at Amsterdam to the time of his death, which happened on the 8th of May 1733. He was twice married, but it does not appear that he left any children.

Great part of Picart's life was spent in making drawings, which are highly finished, and sufficiently testify the fertility of his invention. He understood the human figure, but in the airs of his heads followed too much the fashion of affectation which Coypel had led. His professional industry must have been great, for besides making these highly finished designs, the number of his engravings are not fewer than thirteen hundred.

Most of these plates indeed were small, and were engraved as embellishments to books, for which he was famous. His style consisted chiefly of etching, and bears considerable resemblance to that of Le Clerc. According to Watelet, the taste of the Dutch amateurs of that day impaired the talents of our artist, by inducing him to deviate from the path which nature had pointed out to him, and while he accumulated a fortune, he lost the esteem of the judicious. If his larger works were done to please those amateurs, Watelet's remark is not without foundation, for they are cold, tame, and tasteless, when compared with his small plates.

He scraped a few mezzotintos, among which is a Nativity from Carlo Maratti, and, possessing a certain degree of dexterity in imitating the works of other artists, he undertook, towards the close of his life, what he called *innocent impostures*, which, however, were not published till after his death, and which Strutt thinks had better not have been published at all; it consists of seventy-eight plates, forming, with the preliminary discourse, explanations, and list of his works, a small folio volume.

Of his other engravings, the most remarkable are, "The Massacre of the Innocents," in small folio, from his own design, the first impressions of which are known by their being printed before the crown was placed on the head of Herod. "The Epithalamia," a set of twelve plates, valued for the taste and delicacy with which they are executed, and consisting of eight prints lengthways, and four uprights, in quarto. "The Annals of the Dutch Republic." Of these are particularly remarkable the frontispiece, which is "The prince of Orange," "The Massacre of De Wit," and "The Synod of Dort;" five allegorical frontispieces for Roman Antiquities, Religious Ceremonies, Banier's Ovid, and the Dictionnaire and Atlas Historique, folio. "Philosophers in Search of Truth, at the Head of whom is Descartes," dated 1703, in folio. "Festival of the Gods, and of the Cæsars," a subject taken from the Cæsars of the Emperor Julian, in folio. "The Triumph of Painting," engraven in 1725, in folio. "The Children of Niobé, pierced by Arrows," in folio. Two satirical folio prints, against the administration of law. "A Monument consecrated to Posterity, in Commemoration of the incredible Folly of the 20th Year of the Eighteenth Century."

From the compositions of other masters Picart has engraven "Time delivering Truth from the Yoke of the Passions." "The Remembrance of Death, or Shepherds of Arcadia;" and an allegorical dance, entitled, "The Picture of Human Life," all after Poussin. After Le Sueur he has engraven a pair of "The Muses, Calliope and Terpsichore," and "Darius causing the Tomb of Queen Nitocris to be opened, in the Hope of discovering a Treasure;" and after Le Brun, "Hagar dismissed from the House of Abraham," dated 1707.

His principal portraits are those of Stephen Picart the Roman, engraver to the king, &c. designed in 1715, (en Medallion,) and engraven by his son Bernard in 1730, in small quarto; Roger de Piles of Nevers, ipse pinxit, an etching dated 1714. The following kings of England after Vandyke, Kneller, and Vanderwerf, Charles I, Charles II., James II., William III., and George I. Prince Eugene of Savoy, after Van Skuppen. Louis, prince of Asturias; John de Wit, grand pensionary of Holland; Edward Clarendon, lord chancellor of England, after Zoust. Lord William Russel, and Frederic, duke of Schomberg, after Kneller. Bishop Burnet, after Hoadley. Francis Pierre, cardinal de Fox, (who terminated the schism, and gave peace to the see of Rome,) and a medallion of Philip, duke of Orleans, supported by Apollo and Minerva; after A. Coypel.

Nicholas Petau was the son of James Petau, an engraver from Antwerp. He was born at Paris in the year 1633, and died in the same city in 1676. He probably, judging from the style and character of his engraving, studied in the school of de Poilly. He worked with the graver only, and appears to have handled that instrument with facility, but his extremities are somewhat heavy, the degree of correctness he has attained in his drawing is a laboured correctness, and the similarity of texture which he has spread over his flesh, draperies, and back-grounds, give a certain character of insipidity to his engravings. Watelet however praises the works of this artist somewhat highly, and particularly his Holy Family, after Raphael, for beauty of tooling, purity of outline, vigour and justness of effect, and the true rendering of the characters of Raphael.

The following engravings by this master are held in most esteem, beginning with the historical subjects, which are all in folio.

Ths above-mentioned "Holy Family," after Raphael, wherein St. John is kneeling, as if to receive the benediction of the infant Saviour. "A Madonna reading, with the Infant in her Arms," after Guerchino, an oval. "Angels weeping over a Dead Christ," after the same. "Christ in the Sepulchre, with several attendant Angels," after Carracci. "The Annunciation," after Ph. Champagne. "Jesus Christ, the Virgin, and St. John in the Clouds, interceding for St. Bruno, while several Monks are seen on their Knees," after the same, engraven in 1657. "A Magdalen in the Desert," after the same. "A Holy Family," where the infant Jesus is seen caressing the little St John, after I. B. de Champagne. "St. Sulpice, or the Bishops assembled in Council," after the same. "A Bust of the Virgin," after Le Brun. "A Holy Family." wherein an angel is seen presenting a basket of flowers to the infant Jesus, after Villequin.

His principal portraits are in folio, and are those of Alexander VII., on a pedestal, inscribed P. Mignard pinx. Romæ, N. Pitau sculp. Parisiis, 1662. Louis XIV., a three-quarter figure in armour, Cl. le Feure pinx. Louis Dauphin, son of Louis XIV., after the same. Benjamin Prioli writing the history of France in Italian; after the same, smaller in size. Nicholas Colbert, bishop of Luçon, after the same. Alexander Paul Peteau, counsellor to the parliament, after the same. Henri-Louis Hubert de Montmor, after Champagne, 1667. Oliver Cromwell, after Vanderwerf. Ambrose Chapelle, bishop of Anvers, seated at a table, after H. Perez Brant. Caspar de Daillon du Lude, bishop of Albi, after Juste van Egmont. Vincent de Paul, pastor of the congregation of St. Lazarus, after S. François

çois. Sir Francis de Sales, biſhop and prince of Geneva, after nature, and Louis Alexandre de Bourbon, count de Thouloufe, and admiral of France, after Gobert, inſcribed N. Pitau junior ſc.

Louis Coſſin was born at Troyes, in Champagne, A. D. 1633, and lived till about the cloſe of the century. For ſome reaſon or other, he frequently altered the orthography of his name, and Coquin, Cauquin, Coſſin, and Coſſinus, are all the ſame perſon. He worked, with the graver alone, in a poor and taſtel ſ; ſtyle, and is alſo deficient in drawing and chiaro-ſcuro. His beſt hiſtorical engravings are in folio, and their ſubjects as follow :

" A Madonna" after Le Brun, and, from the ſame maſter, " The Martyrdom of St. John the Evangeliſt." " The School of Athens," after Raphael, a very large plate. " Paul ſtoned at Lyſtra," after J. B. Champagne, and a figure of ſculpture, publiſhed in the Cabinet des Beaux Artes, 1690.

The chief of Coſſin's portraits, which are juſtly held in more eſteem than his hiſtorical works, are thoſe of Louis XV., as large as life ; and inſcribed L. Coſſin ad vivum pinx. et. ſc. Jean Doujat Juris-conſulto François, after F. Suré. Valentin Conrat, of the French Academy, after C. Le Fevre. Francis Chauveau, deſigner and engraver, after the ſame. Louis Roupert, a goldſmith of Metz, inſcribed P. Rabon pinx. L. Coſſinus ſc. Jean de Schulenbourg, comte de Mondejeux, after Bernard, L. Coquin ſc.; and Charles Jean Comte de Koenigſmark, after M. Dahl, all in folio.

Gerard Edelinck, the countryman of Bolſwert, Vorſterman, and Pontius, appears to have formed his ſtyle of engraving before he quitted Antwerp, and probably from ſtudying the works of thoſe diſtinguiſhed maſters. He arrived in Paris ſoon after the middle of the ſeventeenth century ; where his merit immediately ſhone forth, and in that age and country of liberal patronage readily procured him the favour and protection of Louis XIV. He became a member of the French Royal Academy, and the king honoured him with an apartment at the Gobelins, an annual penſion, and the title of Chevalier. In the year 1707 he died in the French metropolis at a very advanced age.

Though Edelinck was contemporary with Audran, and muſt have ſeen the vigour and pictureſque feeling which the admixture of etching imparted to his hiſtorical works, and muſt have heard, and probably joined in, the encomiums that were juſtly beſtowed on them, he did not deviate from that mode of building up for himſelf, a lofty and laſting reputation, which nature and education had marked out for him. Reckleſs of the halcyon gales which ſeemed to court his canvas, he ſteadily purſued his original courſe ; and with the graver alone he ploughed up the ample field of his fame. Wedded to the ſtyle he had adopted in the earlier period of his life, he did not, in his maturer age, allow the ſuperior charms of the youthful and admired miſtreſs of Audran to diſturb his ſettled affections.

It would appear, however, that the cognoſcenti of the ſeventeenth century were much divided in opinion, as to the relative merits of theſe two modes of engraving, and, notwithſtanding what is now thought on the ſubject, Edelinck might poſſibly, among his contemporaries, find even more admirers than Audran. Much to the honour of the latter artiſt, it has been ſaid that he recommended Edelinck to Le Brun's notice, to engrave " the Tent of Darius," from a modeſt perſuaſion that his own powers were inadequate to the delicacy of the taſk. It is pretty well known that at the period now ſpoken of, the means were by many miſtaken for the end of engraving. The ignorant gradually learn to worſhip the idol itſelf, that was at firſt ſet up merely to ſtimulate their devotion, and lead their minds to the contemplation of divine perfections ; and clear and clean cut lines were a quality in the engraver's art more vulgarly obvious than exquiſite drawing, or delicate energy of expreſſion.

Such might be the nature of the admiration of the majority with reſpect to engraving at that period; but the art of Edelinck added, to theſe more obvious and ſuperficial qualities, the profundities of ſcience ; and though the freedom, delicacy, and addreſs, with which he handled his graver, are admirable, yet his application of that freedom, delicacy, and addreſs, is not leſs ſo. How well he underſtood the human figure, and how beautifully, in engraving his fleſh, he tempered his courſes of lines, and mingled them with ſtippling, may be ſeen in the figure of Chriſt in his large plate of " The Crucifixion," after Le Brun : the head of this figure alſo ſhews how deeply he ſtudied the energies and ordonnances of character and expreſſion in the originals which he copied, and how thoroughly empowered he was to render them with effect.

Under ſuch circumſtances, though poſterity ſhould beſtow the palm of ſuperiority on Girard Audran, it will not be ſurpriſed that Edelinck choſe rather to be the firſt engraver in a ſtyle that had already been honoured with general approbation, than to enter into a rivalry, which might have ended in confirming him *the ſecond* hiſtorical engraver of his age.

Strutt writes of our artiſt with great truth, that " he ſucceeded particularly in the heads of his figures, which are often uncommonly fine. He certainly underſtood the human figure, yet he did not draw it with that great taſte and correctneſs which is ſo remarkable in the prints of Girard Audran; neither are his hands and feet marked in that maſterly manner, or with equal truth. And if we compare that excellent engraving by him, repreſenting the tent of Darius, from Le Brun, which he has finiſhed in ſo beautiful a manner, with the battles of Alexander, by Audran, from the ſame maſter, we ſhall readily agree, I believe, that the animation, correctneſs, and taſte, which we find in the latter, amply compenſate for the want of that clearneſs and neatneſs, which appear in the execution of the former.

Among the moſt eſtimable prints by this great artiſt, may be reckoned the following:

" A Battle between four Horſemen," with much of the general air and character of a compoſition of Rubens, after Leonardo da Vinci, miſtakenly inſcribed on the plate " De la Finſe pinxit," a ſcarce and valuable print, in large folio. " A Holy Family," with Elizabeth, St. John, and two angels, one of which is ſcattering flowers, an upright folio, from the famous picture of Raffaelle, which was in the king of France's collection. The firſt impreſſions are known by their having been taken before the arms of Colbert were added at the bottom of the plate; the ſecond edition is with the arms, and in the third the arms are taken out, but the place where they had been inſerted is very perceptible.

From the pictures of Le Brun, Edelinck has engraven " The Crucifixion of Chriſt," a very large and beautiful engraving, on which we have already commented, and which, from its large dimenſions, (three feet in height,) the artiſt has engraven on two plates. " Mary Magdalen bewailing her Sins, and trampling upon the Riches of the World," a middling-ſized upright, the proof impreſſions of which are known by their having been taken before the ſubject was ſurrounded by a narrow border. " St. Louis at Prayers," and St. Charles Boromeus, its companion. " Alexander entering the Tent of Darius," a very large print, engraved

on

on two plates of a ſize correſponding with Audran's battles and triumphal entry into Babylon, (of which the firſt impreſſions have the name of Guyton, the printer, ſcratched underneath with the dry needle.)

Edelinck has alſo engraven, in concert with Drevet, another large print, on two plates, of the ſame ſubject, (Alexander entering the Tent of Darius,) from the original of P. Mignard: and from P. Champagne, "Moſes with the Tables of the Law," engraved in concert with Nanteuil.

Among his beſt portraits will be found thoſe of C. Le Brun, from a painting by himſelf; the three following, after Hyacinthe Rigaud; namely, M. d'Hozier the genealogiſt; Martin Vanden Bogaert, the ſculptor; and Madame Helyot; and after P. Champagne, a portrait of himſelf, and thoſe of Arnald d'Andilli, and Nathaniel Dilgerus.

Guillaume Chateau, (or Caſtellus,) was born at Orleans A.D. 1633. His ſtrong deſire of purſuing the fine arts induced him at an early period of his life to remove to Lyons, in order to viſit Italy at a convenient opportunity. After having worked in that city for ſome time at the profeſſion of engraving, he determined to go to Rome; where hearing, on his arrival, of the reputation which Frederic Greuter had acquired as an engraver, he courted his acquaintance and became his diſciple. Under Greuter he completed his ſtudies; was ſoon employed to engrave the portraits of the popes; and had numerous other plates put into his hands, in which he ſucceeded ſo well as to eſtabliſh his character as an artiſt.

He now travelled to Florence, Parma, Genoa, and other ſeats of art, in order to contemplate the works of the great maſters, and afterwards returned to Lyons, where he remained ſome time with the marquis de Sonozin. From Lyons he removed to Paris, and continued to reſide there under the patronage of M. Colbert till the time of his death, which was occaſioned by a violent fit of the cholic in the year 1683.

Chateau worked chiefly with the graver, of which he poſſeſſed great command; but in ſome inſtances has etched his landſcape back grounds. There is much clearneſs in his ſtyle, but from the ſquare manner in which his firſt and ſecond courſes of lines interſect each other, a cold and metallic effect is produced. His drawing is ſtiff and laboured, and not always correct, and the extremities of his figures are but poorly marked: in ſhort, his works ſeem produced by labour and care, rather than by genius and taſte.

The principal hiſtorical engravings of Chateau are of the folio ſize, and their ſubjects as follow:

"The Prophets David, Daniel, Jonas, and Habakkuk," from a painting attributed to Raffaelle, in the church of Madonna del Popolo, but according to Botari, painted by Roſſo, engraved on two plates. On a third plate, our artiſt has converted theſe doubtful prophets into the four evangeliſts. "The miraculous Fiſh," after Raffaelle. "The Baptiſm of Jeſus Chriſt," after Albano. "Ananias reſtoring Sight to St. Paul," after P. da Cortona. "The ſtoning of St. Stephen," after Carracci. "The Aſſumption of the Virgin," after Carracci. "The Saviour with the Croſs, meeting St. Peter," who ſays to him, "Domine quo vadis, &c." after the ſame. "Repoſe during the Flight into Egypt, or a kneeling Madonna admiring the infant Jeſus lying aſleep on ſome Straw," an oval, engraven by Chateau, but without his name, or that of the painter, which is Correggio. "A Holy Family," in which the infant Saviour is ſtanding on a globe, after Carlo Maratti.

From the admirable picture of Pouſſin, Chateau has engraven "The Iſraelites collecting Manna in the Wilderneſs;" "Chriſt reſtoring Sight to the two blind Men of Jericho;" "St. Paul caught up into the third Heaven;" "The Death of Germanicus," one of his beſt prints; and "The Preſervation of the young Pyrrhus," all, excepting the latter, engraved for the collection entitled "The king of France's Cabinet." After Noel Coypel we find "A Holy Family," containing five figures, and a Madonna and Child, in a border of flowers; and after his own compoſition, "A Holy Family," and "A Repoſe during the Flight into Egypt," the latter of which is partly a plagiariſm from Correggio.

Of his portraits the beſt are, the biſhop of Ruette; Jean Baptiſte Colbert, an oval; and thoſe of the popes, which have been already mentioned.

Nicholas Chateau is ſuppoſed to have been a relation, and perhaps the ſon, of William. He was born at Paris A.D. 1680, but of his death, or the courſe of his ſtudies, we find no account.

His beſt works are a portrait of Boucherat, from a drawing of his own. A half-length figure of "A young Lady richly attired and holding a Maſk," after Santerre, and dated 1708. "A young Lady dreſſed in the Spaniſh Coſtume, ſitting," after the ſame painter. "Summer," after Peter Van de Berg. "A young Female ſinging, habited in the Grecian Coſtume," a ſmall folio, dated 1708. "Venus attempting to diſſuade Adonis from going to the Chace," dated 1706. "The Transformation of Daphne into a Laurel." "Rinaldo and Armida," dated 1708, all after L. Silveſtre. "St. Jerome in the Deſart," after Balth. Peruzzi, engraven by Chateau in conjunction with L. Surrugue.

Pierre Simon was born at Paris in the year 1640. He preſumptively ſtudied in the ſchool of Nanteuil. Like him he painted and engraved portraits from the life, and theſe are his beſt works: indeed they poſſeſs no inconſiderable degree of merit.

The only hiſtorical work of Simon with which we are acquainted is the "Martyrdom of St. Cormo and St Damien," a folio plate, after Salvator Roſa. His portraits, which in ſtyle reſemble thoſe by Nanteuil, are not uncommon. Among the beſt of them will be found thoſe of Frederic Baroccio, the painter, in quarto. Charles D'Aelley, duke de Chaulneſs, after de la Borde, in folio. Jacobus Cardinalis Roſpigliоſius, a half-length figure in an oval, very large and ſurrounded by an ornamental border.

In the following, the heads (as appears to have been much the faſhion of the times) are as large as life. That portraits of this very large ſize ſhould be engraven in lines, would appear as ſurpriſing as it is unneceſſary, if it were not ſo common. Louis XIV. after Le Brun, dated 1677. Louis de Bourbon, prince of Condé, dated 1678. Anne Maria Louiſa of Orleans, ducheſs de Montpenſier. Elizabeth Charlotte Palatine, ducheſs of Orleans; all from pictures by Simon himſelf, and Leo Potier de Geſores, abbé and count of Bernais, after De Troy.

Guillaume Vallet was born at Paris A.D. 1636. After acquiring the rudiments of engraving in France, and apparently in the ſchool of F. de Poilly, he travelled to Italy for improvement, but returned after ſome years reſidence at Rome, and died in his native city in the year 1704. He worked with the graver only, and his ſtyle bears an inferior reſemblance to that of de Poilly: yet he is occaſionally deep-toned and vigorous in his chiaro-ſcuro. His principal hiſtorical engravings, which are of the folio ſize, are as follow:

"The Nativity," almoſt ſquare; "Melchiſedec bringing Preſents to Abraham," and the "Lord's Supper," all after Raphael, and the latter inſcribed "Pictum a Raphaele Urbinate Romæ in Palatio Vaticano." "A Holy Family" after

after C. Cæfio, in which the infant St. John is receiving the bleſſing of our Lord. "The Virgin waſhing Linen," after a painting of Albano; a piece commonly known under the name of the "Laveuſe." "A Holy Family, or the Virgin adoring the Sleeping Jeſus," after Guido, almoſt ſquare. Two other holy families after A. Carracci. "Repoſe during the Flight into Egypt," after C. Maratte; inſcribed "Torrentum pertranſivit anima noſtra." "The Annunciation," after Guil. Courtois, brother of Bourguignon. "The Reſurrection of our Saviour," after N. Loir. "St. John the Baptiſt in the Preſence of Herod," after Le Brun. "The Adoration of the Kings," painted at Rome by Pouſſin. "The Aſſumption of the Virgin," after J. Miel, engraved at Rome. "A Holy Family," in which the Virgin is ſeen with the infant Jeſus on her knees, holding out a branch of cherries to St. Joſeph, after Jac. Stella. "Jeſus Chriſt on the Croſs, adored by Angels," after the ſame.

The moſt eſteemed portraits from the graver of Vallet, are thoſe of Alexander Algardi, ſculptor and architect, in 4to. Andrea Sacchi, painter, after C. Maratte, engraven in 1662, in 4to. Olympia Maidalchini Pamphili, Principeſſa di S. Martino, engraven at Rome in 1657. Charles Emanuel, duke of Savoy, in folio, after his own drawing.

The following are all after Paillet, and of the folio ſize. Buſt of Pierre Corneille, crowned by Melpomene and Thalia. William le Roux, biſhop of Perigueux. Antoine Daubray, count d'Offremont, counſellor of ſtate. Nicolas Favre de Berlife, count of the holy conſiſtory, and "St. Francis de Sales preſented to pope Alexander VII." large, and engraved on two plates.

Anthony Maſſon was born in the Orleannois in the year 1636. He viſited Paris in his youth, but had previouſly been brought up like Coſmo Armſtrong of England, (of whom future biographers will ſpeak,) to the profeſſion of gun-engraving. He who has acquired the power of cutting ſteel with preciſion, has well prepared himſelf for the taſk of cutting copper with freedom, firmneſs, and facility. It was probably in part owing to this early circumſtance of the education of Maſſon, that he acquired thoſe ſurpriſing powers in handling his graver, which Europe has ſince beheld with admiration.

After the example of Nanteuil, who was but ſix years older than himſelf, he now ſat down to acquire the talent of painting portraits from the life, and many of his engravings are done after his own originals. He appears to have had no maſter in fine art, as in ſome reſpects he had no equal: he probably formed his ſtyle, partly from ſtudying the engravings of Nanteuil, but his invention was more vigorous and unbridled; and though he has much leſs of ſimplicity, he has, in his beſt performances, not leſs of exquiſite feeling, of which it was ſcarcely poſſible to have more. In ſome of his works indeed, he appears as if he meant to be capricious and extraordinary, rather than natural, and to ſurpriſe our ſenſes rather than ſatisfy our judgment; and in his "Jeſus Chriſt with his Diſciples at the Houſe of Emmaus," commonly known by the name of "The Table Cloth," as well as in the face of his elector of Brandenbourg, and other of his portraits, are many of theſe eccentric paſſages, though mingled with others of uncommon merit. In the arms of the figure immediately to the left of Jeſus Chriſt, in the drapery and hat of the diſciple to the right, and in the clouds above, Maſſon has twiſted and twirled his lines about, as if to ſet ſyſtems at defiance. The whole of the back ground is wild and ſingular, and Watelet has remarked of the dog which is under the table, that he looks as if formed of ſtraw: yet notwithſtanding theſe, and other ſeeming aberrations from all pre-conceived rule, here is ſuch varied expreſſion of the textures of ſubſtances; ſo much harmonious keeping; and the tone of Titian, after whom it is engraved, is ſo truly rendered, that it has, ever ſince its production, been regarded as a valuable ſchool for engravers, and a maſter-piece of the art.

His portrait of Guillaume de Briſacier, commonly known in England by the appellation of "the Grey-headed Man," is another wonderful piece of engraving; and Watelet has juſtly ſaid of it that here we at once recognize the complexion of the original, and the firm ſoftneſs of fleſh in the face, while his hair, and the fine lace of his neck-bands, are not leſs delicately and beautifully wrought.

His portrait of Oliver d'Ormiſſon is alſo extremely beautiful, and is engraved with much more ſimplicity of ſtyle, if we except the operoſity of the hair; while in that of Guido Patin, he has daſhed and pranced about in all his former curvetings and vagaries, yet has harmoniſed the whole ſo admirably, that the moſt faſtidious taſte cannot but acquieſce in the pleaſure it inſpires, and welcome home the performer after his *ad libitum* flouriſhing.

Watelet has many ſenſible and judicious remarks on the ſtyle of this very celebrated engraver. He diſcommends his favourite practice of repreſenting ſingle hairs, detached from the maſs; and in ſpeaking of a portrait which the preſent writer has not ſeen, that of Charles Patin, he ſays "it poſſeſſes much depth of tone, and almoſt exhibits the appearance of real life: we ſee the ſatirical ſmile of this phyſician finely diſplayed—leſs ſo it is true, than that of his father—and his eyes gliſtening with malice; (this ſeems more than ſhould belong to the portrait of a phyſician)—the ermine of his robe is likewiſe pourtrayed with the greateſt accuracy; but in viewing more nearly the lines which conſtitute the face, I obſerve much ſingularity in their diſpoſition, as thoſe which deſignate the noſe proceed afterward to form the cheek; I am diſpleaſed when I examine thoſe of the forehead, and overwhelmed with aſtoniſhment when I behold one ſtiff courſe of lines employed to expreſs the chin."

Another of his moſt meritorious works is the portrait of Gaſper Charrier, after Blanchet, where, though the hair appears too briſtly for human hair, the face is moſt exquiſitely engraven, and the eyes have never been ſurpaſſed either for form, feeling, fire, or the animated humidity of the cryſtalline humour.

On the whole, that characteriſtic mark of genius which diſpoſes us to regard an artiſt rather by the dimenſions of his merit, than by his freedom from defects, belongs among engravers pre-eminently to Maſſon. His hiſtorical works, of which we ſhall next proceed to mention the moſt eſteemed, are few compared with his portraits, but are of the folio dimenſions.

"The Holy Family," from N. Mignard; "St. Jerome," and "Jeſus of Nazareth," the latter ſmall; "The Aſſumption of the Virgin," a large upright from Rubens, eſteemed one of the moſt rare and beautiful of the engravings of Maſſon, though it bears not his name. "The Brazen Serpent," after a grand compoſition of Le Brun, engraved on two plates on account of its large dimenſions, and the before-mentioned Jeſus Chriſt at the table of Emmaus, after Titian.

The portraits from the graver of Maſſon are ſome of them in large, and others in ſmall folio, and are principally as follows, beginning with the ſmaller.

Antoine Maſſon of the royal academy, engraver in ordinary to the king, ſe ipſe fecit; Frederic William elector of Brandenbourg, dated 1683, (a ſcarce print). Guy, or

Guido Patin, doctor of medicine at Paris 1670, extremely rare and in an extraordinary ſtyle. Charles Patin, (ſon of Guy) doctor of medicine; another of the chef d'œuvres of Maſſor. Marin Caræus, phyſician to the king; after P. Mignard, dated 1665. François Marie, doge of the moſt ſerene republic of Geneva, 1685. Pierre Dupuis, painter to the king, N. Mignard pinx. 1663. Hardouin de Beaumont, archbiſhop of Paris, N. Mignard pinx. 1664. Gaſpar Charrier, ſecretary to the king, Thomas Blanchet pinx. Emanuel Theodore de la Tour, of Auvergne, duke d'Albert, N. Mignard pinx. Alexander du Puy, marquis of St. Andre, De Seve pinx. Louis, duke de Vendome, P. Mignard pinx. Michael Colbert, abbé of Premontres, 1674, Maſſon pinxit. William de Briſacier, ſecretary to the benefices in the gift of the queen, N. Mignard pinx, 1664; a very capital engraving, commented upon in our biography of the artiſt. Olivier le Fevre d'Ormeſſon, preſident of the parliament, 1668. Antoine Turgot de St. Clair, maſter of requeſts, 1668. Marie de Lorraine, ducheſs of Guiſe, N. Mignard pinx.

Portraits in very large folio. Anne of Auſtria, queen of France, P. Mignard pinx. Maria Thereſa of Auſtria, queen of France, N. Mignard pinx. Maria Anne Victoire de Baviere, dauphineſs of France. Louis Auguſte, duke of Maine, ad vivum ſc. Jean Jacques de Meſmes, count d'Aveaux, 1683. François de Beauvilliers, duke of St. Aignau. François Rouxel de Medavi, archbiſhop of Rouen, 1677. Jerome Bignon, librarian to the king, 1686. Denis Marin, ſecretary to the king, 1672. Louis Verjus, count de Crecy, counſellor of ſtate, 1679. Nicolas de Lamoignon, count de Courſon, 1676. Count of Harcourt, repreſented as far as the knees, a celebrated portrait, known under the name of "Cadet de la peree," N. Mignard Aveni pinx. Ant. Maſſon ſc. a maſterpiece of engraving.

In the following inſtances the heads are of the natural ſize; but on this immenſe ſcale Maſſon did not attain the ſame perfection, as on a ſmaller; his force being laviſhed and loſt in unneceſſary exertion. Louis XIV, in a hat, ad vivum fecit, 1687. Louis XIV., after le Brun; a large oval. Louis dauphin, ſon of Louis XIV, in a hat. Jean Baptiſte Colbert, miniſter to the king, 1677. Francis de Harley, archbiſhop of Paris, 1684. Claude du Houſſet, chancellor to the king's brother, 1681. Henri de la Tour d'Auvergne, viſcount de Turenne. Francis Michael le Tellier, marquis de Louvois. Nicolas Potier de Novien, firſt preſident of the parliament, 1679. William de Lamoignon, firſt preſident of the parliament, 1675. Charles Colbert, marquis de Croiſſi, H. Caſcar pinx. 1681.

Madeleine Maſſon, the daughter of Antoine, was born at Paris about the year 1646. She was educated under her father, and engraved in the ſame ſtyle as himſelf. Her prints are much valued, and are equally rare as thoſe of her father.

The following are a few of her moſt diſtinguiſhed productions:

Elizabeth Charlotte, Palatine, Ducheſs of Orleans, the head as large as life, and inſcribed "Mad. Maſſon ſc. under the direction of her father," in folio. Elizabeth d'Orleans, Ducheſs of Alencon. P. Mignard pinx. the ſame ſize. Maria Thereſa of Auſtria, queen of France and Navarre. Mad. Maſſon fec. the ſame ſize. Elizabeth Maria Joſephine, Infanta. Id. ſc. ſame ſize. Victor Amadee II. duke of Savoy. Mad. Maſſon, ſc. the ſame ſize. Louis-Henri de Gendrin de Monteſpan, a portrait painted by her father, and engraven by Madeleine Maſſon, of the ſame ſize as the above. The great number of thoſe coloſſal engravings that were performed about this period may be regarded as one of the faſhionable follies of an age, when the *big* was too much miſtaken for the *great*.

René Lochon was born at Poiſſy about the year 1636. He ſettled at Paris, where he publiſhed a great number of portraits, as well as hiſtorical ſubjects after different maſters. His ſtyle of engraving reſembled that of Nanteuil, eſpecially by its mellowneſs, though his works are decidedly inferior to thoſe of that great maſter. Thoſe moſt worthy of diſtinction, are "Jeſus Chriſt bearing the Croſs," after Carracci, and a "Holy Family," after N. Coypel, dated 1668, both in folio.

The beſt of his portraits are alſo in folio, and are thoſe of, a young magiſtrate in an octagonal border of oak leaves, inſcribed R. Lochon ad vivum del. et fec. 1657. Charles de Bourbon, biſhop of Soiſſons, Ib. 1657. Euſtaches de Lepeville, biſhop of Conſtance, 1661. Felix Vialart, biſhop of Chalon. Belthaſar Phelipeaux de la Vrilliere, abbe; ad vivum fec. 1667. Jerome Bignon, a celebrated author of the laſt century. R. Lochon ad vivum furtim del. et ſc. Louis de Marillac, doctor of the Sorbonne, 1696. Paul the younger, of the company of Jeſus. Harduin de Pereſix, archbiſhop of Paris, 1676, after Champagne. Antoine Arnauld, after the ſame.

Jean Berain was born at Paris A.D. 1636 and died in the ſame city in the year 1711. He has the title of ornamental deſigner to the king, and ſo great was the reputation he enjoyed, that he was conſtantly employed, either for the court or city, in ornamental decorations. His brother Louis, who was alſo a ſkilful deſigner, aſſiſted him in theſe works, and he was alſo occaſionally aſſiſted by Chaveau and Le Moine.

To his etchings he has not often ſubſcribed his name; they are neat, but too ſtiff and taſteleſs to merit any other praiſe. His principal work is a large folio book, (of which the frontiſpiece is by Scotin,) entitled "Ornamens du Peinture et de Sculpture, dans de Gallerie d'Apollon du Louvre, et dans le grand apartement du Roi aux Tuilleries."

His other works on copper are fourteen plates forming a ſet of heraldic devices in 4to. three folio plates of ornaments, invented and executed by J. Berain; a comic ſubject of a man leading two dogs; an opera ballet, and two plates of Mauſolea.

Simon de la Roiſſiere was born at Paris in 1637. He engraved not only after his own deſigns, but alſo after thoſe of Sebaſtien le Clerc. He likewiſe executed medallions of the popes from Martin to Innocent XI. for the edition of P. Molinet canon of St. Genevieve, a work in folio, printed in 1679. Several of the plates in the work entitled "the Cabinet of the King," were alſo from the hand of this artiſt; whoſe beſt performances, on the whole, are, "The Death of a Prince ſurrounded by his Court;" frontiſpiece and ſeveral vignettes for M Blondel's grand courſe d'architecture. Some plates for Jean Picart's work on the dimenſions of the earth. Some plates for the work of Antoine Deſgodets, entitled, "Traité des edifices antiques de Rome;" a ſet of forty plates of antique medals in folio; "A View of the Palais Royal," in two plates, and a ſet of twenty-ſix plates of views, plans, elevations, &c. of the royal palaces, of which, however, Boiſſiere engraved only a part.

Jacques Lubin was born at Paris in the year 1637. He was probably the diſciple of G. Edelinck, whoſe ſtyle he ſucceſsfully imitated. Lubin engraved a great number of portraits, and was employed, in conjunction with other able engravers, in executing the plates for Perault's memoirs of illuſtrious men. His principal works are, the portraits of Armand Jean du Pleſſis, Cardinal duke de Richelieu,

Jean

Jean Pierre Camus, biſhop of Belley. Robert Arnauld d'Andilly, (a celebrated author.) Jean Paſſire Maſſon, (a celebrated advocate.) Vincent Voiture, of the French academy. Pierre Corneille, of the French academy. Olivier Patru, of the French academy, and Jean Baptiſte Colbert, miniſter of ſtate, all in folio. The only hiſtorical plate from his graver, with which we are acquainted, is alſo in folio, and its ſubject "Jeſus Chriſt laid in the Sepulchre;" after le Sueur.

Simon Thomaſſin was born at Troyes in Champagne in the year 1638, and was a deſcendant of Philip Thomaſſin, the tutor of Callot, who flouriſhed at Rome toward the cloſe of the ſixteenth century. After acquiring the rudiments of drawing and engraving in his natal city, he repaired to Paris, and from thence to Rome, where he ſtudied in the academy founded by the French king for the improvement of thoſe young artiſts who were ſent from France. He afterwards returned to Paris, where he became a member of the Royal Academy, and where he died in the year 1722.

The ſtyle of Thomaſſin's engraving, which is performed with the graver alone, is neat and clear, but laboured and dry; his drawing is tolerably correct, but ſomewhat manncred; he appears to have ſuffered, rather than enjoyed, his various taſks, and to have poſſeſſed "patience under his ſufferings."

His largeſt work is a folio volume, containing two hundred and eighteen plates of the ſculptures which adorn the chateau and gardens of Verſailles; and his beſt hiſtorical works are "The Miraculous Fiſh of St. Peter," after Raphael. "The Reception of the Emperor," after Bon Boulogne, engraven in 1684. "St. Paul carried up into the third Heaven," a circle, engraven in 1684, after Pouſſin. "Jeſus on the Mount of Olives," after le Brun. "Sancta Scholaſtica, cujus Anima de Corpore egreſſa," after J. Jouvenal, all in folio; and the "Transfiguration," after Raphael, the largeſt and beſt of Thomaſſin's hiſtorical works, engraved on two plates.

The beſt of his portraits, are thoſe of Louis, duke de Bourgogne, ſon of Louis dauphin, deſigned and engraven by S. Thomaſſin, 1698; in folio. Maria Adelaide of Savoy, Ducheſs de Bourgogne. Id. del. et ſc. Paul Beauvillier, duke de Aignon, peer of France. S. Thomaſſin ſc. 1695, in folio. Arnauld, cardinal d'Oſſat. S. Thomaſſin fecit, ſculptor Regius, in 4to. Charles XII. king of Sweden, S. Thomaſſin fecit, 4to. Francis Hebert, biſhop of Agen; after du Mee, in folio. Antoine Furetiere, of the French academy. De Seve pinx. in folio. Pierre Corneille, of the French academy. C. le Brun pinx. in folio. Equeſtrian ſtatue of Louis XIV. in bronze, executed by Coyzevox, in folio, and a grand Theſé, with the portrait of Alexander Bournonville. S. Thomaſſin del. et ſc. on two folio plates.

Henri Simon Thomaſſin was born at Paris in 1688, and died in the ſame city in 1741. After having learned the principles of his art from his father, he ſtudied under Picart, whom he accompanied to Holland. After a ſtay of two years at Amſterdam he returned to Paris, and was nominated a member of the academy of painting in 1728. His ſtyle of engraving being coarſe and diſſonant, neither reſembles that of his father Simon, nor that of Picart; neither is he at all ſuperior to his father in his knowledge of the human figure.

His principal hiſtorical works are in folio, and are entitled as follows: "Adam and Eve out of Paradiſe, or the Man condemned to Labour," after a painting of Dem. Feti, in the cabinet of Crozat. "Melancholy," a kneeling figure, meditating on a ſcull, after the ſame maſter, and from the ſame collection. This print is one of the beſt of his engravings, and ably executed. "The Pilgrims of Emmaus," after a painting of Paul Veroneſe, in the collection of Crozat. "A Woman at the Bath, attended by two others, one of whom raiſes her Robe, while the other waſhes her Feet," after Rubens, engraven by H. S. Thomaſſin, under the direction of B. Picart. "The Magnificat, or the Canticle of the Virgin," from a celebrated painting by Jouvenet, in the choir of Notre Dame. "The Wrath of Coriolanus appeaſed by the Tears of his Family," after la Foſſe. "The Plague in the City of Marſeilles, during 1721," (with a deſcription,) painted by J. Fr. de Troy. "Apollo diſtributing Rewards to the Arts and Sciences, and Minerva crowning the Genius of France," a cieling piece painted by P. Mignard for the ſmall apartments of the king at Verſailles. Sim. Thomaſſin filius ſculp. Amſtel. "Nymphs ſurpriſed by Satyrs," from L. Sylveſtre. "A naked Venus aſleep," from Le Brun. "Eneas and Achates entering the Temple where Dido is ſitting," from Coypel, and the following ſubjects from Watteau,

"The Return from a Ball," "Recruits marching to join their Regiment," a Buffoon (dedicated to count Caylus,) "Mezetin playing on the Guitar," a ſet of twelve plates of faſhionable figures, by Thomaſſin, Cochin and others; and another ſet of eight, which are much ſought after by connoiſſeurs. Note, the two latter works are of the 8vo. ſize.

The following portraits are alſo from the graver of the Junior Thomaſſin:

Michal Angelo Caravaggio, reflected in a mirror, which is held by the painter, in 4to. Charles Cignani of Bologna, painted by himſelf. Jean Theery, ſculptor in ordinary to the kings of France and Spain, after Largilliere. Cardinal Fleury, ſupported by Diogenes; after Rigaud and Autreau. Louis, dauphin of France, after Jean Louis Tocqué; and a medallion of Louis XIV. preſented to the Arts by Minerva, after L. de Bologna, all in folio.

Sebaſtian le Clerc was an artiſt of very ſuperior powers. He was the ſon of a celebrated goldſmith of Metz, in which city our engraver was born in the year 1637. He is ſaid to have been educated an engineer, but from an engraved view of his native city, which bears the date of 1650, and which therefore, if his biographers have truly recorded the year of his birth, muſt have been engraven at the age of thirteen; and from an engraved head of Jeſus Chriſt, which is dated in the year 1655, it appears that his paſſion for fine art manifeſted itſelf at a very early period of his life; ſo early, as may well incline us to doubt the fact of his having been educated an engineer, or to abſorb it in the ſtrong and unqueſtionable evidence afforded by this early manifeſtation of his genius for the art of engraving.

He learned the firſt principles of drawing, and probably of mathematics, from his father, or under his paternal roof; and, beſide the above mentioned head, executed ſeveral plates with the graver alone, before he became acquainted with that branch of the art in which he was deſtined to hold ſo diſtinguiſhed a rank.

He was probably unacquainted with etching until after his arrival in the French metropolis, which he viſited with the view of improving himſelf as an artiſt, and of aſſociating with the men of ſcience with whoſe preſence Paris was at that time adorned. Here he became acquainted, and finally formed a ſtrict friendſhip with Le Brun, by whoſe recommendation he diſcontinued his architectural and engineering purſuits, and confined his attention to deſigning and engraving; and here he was introduced, probably by Le Brun himſelf, to the miniſter Colbert, who being made acquainted

with his merits, obtained for him an apartment in the Gobelins and a penſion of eighteen hundred livres, which however was aſſigned to him upon condition of his working for the king alone, who honoured him with the title of engraver royal. He was ſoon after created profeſſor of perſpective in the royal academy, and a Roman knight by pope Clement XI.

In the year 1672, he was appointed to engrave the Mauſoleum, erected by the Royal Academy of Arts, in the church of l'Oratoire at Paris, under the direction of Le Brun, for which he received a penſion of three hundred livres from the academy, and the following year he married Charlotte Jeaune, daughter of Vanden Kirchove, the king's dyer at the Gobelins, by whom he had eighteen children.

It appears that the advantage of a royal penſion in France might, even at that time, be more ſeeming than real. The rapid increaſe of his family, and a ſecret conſciouſneſs, probably, that his inventive talent was reſtrained by his royal engagement, obliged le Clerc to give up that ſettled upon him by the king, on account of the condition annexed to it. Anticipating that he ſhould be more profitably patronized by the public, and feeling the vigorous expanſion of his own powers for original compoſition, he now began that vaſt number of engravings, from his own deſigns, to which his name is annexed, and which amount to upward of three thouſand! many of which are peopled by prodigious multitudes, in all the diverſity of coſtume of the various ages and nations of the earth.

Le Clerc died at Paris A.D. 1714, aged ſeventy-ſeven years, and was buried in the church of St. Hippolito, in which pariſh he reſided.

Perhaps no artiſt has diſplayed a greater diverſity of endowment than Le Clerc. From his mathematical ſcience, and the ſtudies he connected therewith, he became an enlightened architect, engineer, and a teacher of perſpective; from his knowledge of drawing, his various reading, and his ſtudy of the works of Le Brun and Callot; above all from the energy of his own genius, he became an accompliſhed deſigner and engraver, excelling, to uſe the ſentiments of a French writer, in almoſt every department of fine art; hiſtory, landſcapes, animals, ruined and modern edifices, were by turns the ſubjects of his pencil and his graver. His compoſitions are full of knowledge and variety, his draperies ſimple and beautiful, his forms elegant and correct, his heads noble and characteriſtic, while their expreſſion is indicated with the addreſs of a conſummate artiſt. He ſtudied in the ſchool of Le Brun, and if to ſome he ſhould rather appear to have ſtudied Raphael and the antique, this proceeds from the learned manner of Le Brun when reduced to the ſmall ſcale of le Clerc's engravings; for, in conſequence of ſuch reduction, Le Brun loſes his own defects, and retains only the grand ſtyle of the Roman ſchool.

From theſe praiſes of the French writers, Huber, Roſt, and Baſan, ſome ſmall deductions ſhould perhaps be made on the ſcore of national partiality. In his engraving, Le Clerc generally employed ſingle courſes of lines, and with more of the ſpirit and firmneſs of Callot, than of the taſteful airineſs which charms us in the works of Della Bella.

Our limits allow us to mention but few, comparatively ſpeaking, of his numerous works. We begin with thoſe taken from *ſacred hiſtory*.

"The Dream of the Prophet Elias." "The Apotheoſis of the ſame Prophet," wherein the landſcape is a view of the falls of Niagara, both in ſmall folio. "The Repentance of the Ninevites." "The young Tobias with the Angel on the Banks of the Tigris," ſmall folio. "The Calling of Abraham," in 4to. "The Annunciation," inſcribed Virgini ab Angelo ſalutatæ. "The Adoration of the Kings," where a page is ſeen carrying a robe to one of them, a very ſcarce print. "A Holy Family," where the Infant Jeſus is ſeen between the Virgin and St. Joſeph, all three ſtanding. "The Infant Jeſus ſitting, and before him the little St. John, who kiſſes his Hand." "The Good Shepherd," as deſcribed by the prophet Iſaiah. An allegory on the viſions of madame Guyon, a diſtinguiſhed piece in ſmall folio. "St. John the Baptiſt ſitting beneath a Rock." "The Miracle of the Loaves and Fiſhes," one of the chef-d'œuvres of the artiſt, in ſmall folio. "The Saviour ſitting in the midſt of ten Apoſtles." "An Ecce Homo," accompanied with ſeveral ſoldiers. "A Crucifix on a ground of dark Clouds." "The Martyrdom of St. Stephen." "A ſtanding Madonna, incloſed in a Border." "The Virgin borne on Clouds, and attended by Angels," a round piece. "The Virgin with Angels, ſeated with the Infant Jeſus in a Landſcape." "Our Lady of mount Carmel." "The miraculous Image of our Lady of Conſolation at Premy." "St. John the Evangeliſt writing in the Iſle of Patmos." "The Bark of St. Peter," inſcribed Annuerant iis, qui erant, &c.

Subjects from profane Hiſtory, ancient and modern.—"The entrance of Alexander into Babylon," a diſtinguiſhed piece in folio. In the firſt proofs the hero is ſeen in profile, in the ſubſequent impreſſions it is a three-quarter face. "The Apotheoſis of Iſis," in folio. In the firſt proofs dancers are repreſented ſurrounding an altar, in the ſubſequent impreſſions their place is ſupplied by ſacrificers. "Mars" and "Diana," a pair of ſingle figures, in 8vo. extremely ſcarce. "The Map of the Gobelins," a folio print in honour of Le Brun. "The Academy of Sciences," in the firſt proofs of which the ſkeleton of a ſtag and tortoiſe are repreſented in the foreground; a capital piece. "The triumphal Arch of Louis XIV. at the Gate of St. Antoine," a capital piece, in folio. "The Chapel of St. Catherine at Stockholm," which contains the burial place of the kings of Sweden, improperly called the tomb of the king of Portugal, in folio, 1654. "Catafalque erected in the Church of Stockholm for the Obſequies of Charles XI. of Sweden," 1697, in folio. "Catafalque of Chancellor Seguier," a print in great requeſt among connoiſſeurs. A pair in folio of the cielings of the hall and bed-chamber of baron Teſſin, in his hotel at Stockholm, much valued for their taſteful execution. "Proceſſion of the Knights of the Order of the Holy Ghoſt, on the Quay of St. Auguſtin at Paris," in folio. "The Game Keeper of Nantes," a very remarkable piece, engraven in 1668, in folio; (a bad artiſt retouched this plate in 1694, and put upon it re-engraved by Carreau.) Allegory in praiſe of Louis XIV. repreſenting Hercules and Alexander with the motto: "Plures non capit orbes," 1684, in 4to. "Venus riſing from the Sea." A piece termed "la premiere Venus," and engraved for M. Potier, in 1693, in 4to. The ſame piece called "la ſeconde Venus," re-engraven by le Clerc 1711, in the contrary direction. (After the death of le Clerc M. Eiſen added to this plate a Triton, which puſhes the Chariot, and a Cupid flying before it.) "The Tomb of M. Bonneau in the church of Tournay," after Girardon, 1685. "Two Vaſes of Flowers on one Plate, ſurrounded with an ornamental Border," 1656. "The Fortreſs of Montmelion," taken by M. de Catinat, the 21ſt Dec. 1691, in folio.

The following are uſually bound in ſets or ſeries.—Figures illuſtrative of the paſſion of our Saviour, in thirty-ſix ſmall plates. Repreſentation of the inſtitution of the order of Mathurius for the redemption of captives, on eleven plates, including the frontiſpiece, 1654. Another ſeries of prints for the order of Mathurius, eleven plates, 1656; ſcarce. The triumphs

triumphs of Charles IV. duke of Lorraine, on twenty-three plates, of which two are engraved by Dervet of Nancy, 1664, in folio. Hiſtory of Charles, duke of Lorraine, conſiſting of thirty-ſeven plates of hiſtorical ſubjects, and vignettes, in quarto. Twenty-eight plates for the Hiſtory of the Preſent State of the Ottoman Empire, by Briot, Paris 1670, in quarto. A collection of academic figures, in thirty-two plates, with the frontiſpiece, executed for the ſecond edition of "L'Art de Peinture, par Dufreſnoy," Paris, 1673, in 12mo. Ovid's Metamorphoſes, by Benſerade, thirty-nine plates, Paris, 1676, in quarto. The Labyrinth of Verſailles, containing thirty-nine plates of fables, with the frontiſpiece, Paris, 1677, in octavo, of which the firſt edition is now ſcarce. The Fables of Eſop, twenty-three pieces, in ovals. A collection of figures, horſes, landſcapes, &c. dedicated to the duke of Bourgogne, in nine books, including ſixty plates. Characters of the Paſſions, an elementary book after Le Brun, in twenty plates. Elements of Deſign, by Seb. le Clerc, in fifty-two plates. Treatiſe on Geometry, containing (beſides the figures engraven in wood, after Le Clerc, to the number of near three hundred,) eighteen copper-plates by himſelf, Paris, 1690, in octavo. Tapeſtries of the king, on which are repreſented the four Elements, and the four Seaſons, making, with the ornamental accompaniments, forty-eight plates, after Le Brun. The firſt edition is dated 1670, and is in imperial folio. "The Battles of Alexander," after Le Brun, ſix plates with the frontiſpiece, (which repreſents the gallery of the Gobelins,) in ſmall folio. "The Loves of Cupid and Pſyche," four plates, in folio. "The four Victories," repreſenting the ſurrender of Tournay, and that of Douay, the defeat of count de Marſan, and that of the Swiſs Confederacy, in folio. "The Conqueſts of the King," in twenty-eight plates, thirteen of which are engraven by Le Clerc; namely, The Iſle of Rez; Fort de Schenk; the Town of Nimeguen; City of de Grey; Battles of Sintzheim; of Fenette; Meſſina; Views of Agoſta, Bouchain; Battle of Agoſta; Battle of Palermo; L'Eſcalette; Battle of Caſſel; in folio: the other pieces of this collection were engraven by Chatillon, after the deſigns of Le Clerc. "The Leſſer Conqueſts of the King," in eight plates; namely, Views of Meſſina, and Dinant; the Battles of Caſſel, and St. Omer; Audience given to the Ambaſſador of Siam; Demolition of the temple of Charenton; the Combat of Leuze; the Blockade of Namur, in quarto.

Views and other Landſcapes.—"Side View of the City of Metz," engraven in 1650, the firſt eſſay of Le Clerc in the art of engraving. "The Remains of the Aqueduct of Joui, near Metz, and the village of Joui," a pair of landſcapes, engraven in 1656. "The Plan of the City of Metz," taken from the Siege of Metz, by Charles V. deſcribed by Saligna, 1665, in quarto. "A ſtrong Cheateau, built on Rocks in the middle of the Sea," from the hiſtory of the wars of Louis XIV. againſt the Dutch, in 1672. "A ſmall Landſcape," in which three Children are ſeen unrolling a printed Bill, 1620. Twelve views of the Fauxbourgs of Paris, dated 1695. A ſeries of views of gardens, perſpectives of cities, rocks, and ruins, dedicated to the marquis of Beringhen, twelve ſmall pieces, numbered. Thirty-ſeven plates of ſmall landſcapes and figures, deſigned and engraven for the inſtruction of the marquis of Courtenvaux, the two laſt of which are not always found in this collection. In the one is ſeen a cavalier turning his horſe; and in the other an arcade, 1690.

The beſt portraits by Le Clerc are, Sebaſtian Le Clerc ſtanding before a deſk, with ſeveral other figures, a piece entitled "Le Cabinet de M. le Clerc," not finiſhed. Small portrait of a Turk, dated 1656. Abraham Fabert, ſeigneur de Moulin, 1657. Marſhal de la Ferte, rare. Egonde Furſtenberg, biſhop of Straſbourg. Louis Fremin, ſcarce. A knight of Malta, 1659. "Vera Effigies R. P. Di. Philippi, Abbatis S. Agerici Virdunenſis," a whole length figure in a ſmall border, 1660. Torquato Taſſo, and M. Potier, "en medallion."

Louis de Chatillon was born at St. Menehould, in Champagne, in 1639, and died at Paris in 1734. Whoſe diſciple he was, Strutt could not find, nor have the French writers mentioned. He evidently imitated the free ſtyle of Girard Audran, and though he falls ſhort of that great maſter, his prints are not deſtitute of merit. Among the beſt of them may be reckoned,

"The Woman taken in Adultery," after S. Bourdon. "The Converſion of St. Paul," after the ſame. "The Seven Sacraments," painted at Rome by Pouſſin for the Chevalier de Pozzo. "St. John in the Iſle of Patmos," after the ſame. "The Fates weaving the Deſtiny of Maria de Medicis," after Rubens, all in folio. He alſo engraved three books, two of which contain the fountains for the iron horſe at Verſailles, and the third for the pavilions of Marly.

Jaques Blondeau, or Blondel, was born at Langres A.D. 1639. He travelled to Rome for profeſſional improvement, and probably, judging from his ſtyle of engraving, ſtudied there under Cornelius Bloemart, in conjunction with whom, Spierre, Clouet, and ſome others, he engraved a work from the pictures of Pietro da Cortona, in the palace of Pitti at Florence. Blondeau worked, entirely with the graver, in a ſtyle reſembling that of Bloemart, but he by no means equalled that maſter, either in drawing or freedom of execution. His prints are comparatively cold and metallic, and the extremities of his figures heavy, and frequently incorrect.

Of the plates already mentioned from P. da Cortona, he engraved eight of mythological and allegorical ſubjects: they are in ſmall folio, and the few following engravings by this artiſt, (the beſt of his works,) are all of the folio ſize,

"The Martyrdom of St. Lawrence," after the ſame painter. "The Chair of St. Peter," after Bernini. "A Magdalen," after Hyacinthe Calandrucci. "The Circumciſion," after Ciri Ferri. "Chriſt, with the two Maries and St. John at the Foot of the Croſs," after the ſame. "St. Auguſtin appearing to St. Thereſa," after the ſame.

Portraits.—Cardinal François Laurent Brancati, 1681. Cardinal Fortuna Caraffa, 1686. Cardinal Maximilian Gandolfi, archbiſhop of Salzburgh, 1686. Cardinal Opitius Pallavicini. General Eneas, count de Caprara. René d'Eſt, duke of Modena. Jean-George III. elector of Saxony. John Sobieſki, king of Poland. Cardinal Bichi, after Le Bourguignon, in an oval.

Charles Simonneau was born at Orleans in the year 1639, and died at Paris in 1728. He learned the principles of drawing from Noel Coypel, and the art of engraving in the ſchool of William Chateau. His firſt plates were executed with the graver only, in a ſtyle founded upon that of De Poilly; but he afterwards took up the point; and the prints which he produced by an union of both, are infinitely ſuperior to thoſe on which etching was not employed. He drew correctly, and his beſt plates, (which are as follow,) are finiſhed in a neat and pleaſing ſtyle; and are, with an exception or two which we ſhall mention, of the folio claſs.

"The Virgin kneeling, in a Landſcape, holding the infant Jeſus ſeated on the Fragment of a ruined Building, and before him the little St. John on his Knees," after a painting of Raffaelle in the Eſcurial. "Hagar in Deſpair comforted by an Angel," after Andrea Sacchi. "The Vir-

gin kneeling, and holding the infant Jeſus in her Arms, in the midſt of a Concert of Angels," after a painting of Fra. Bartolomeo, in the cabinet of Crozat, almoſt ſquare. "The infant Jeſus ſleeping in a Manger, and adored by the Shepherds," after Carracci. "Jeſus Chriſt converſing with the Samaritan Woman." "Jeſus Chriſt taken down from the Croſs, and placed on the Knees of his Mother," and "The ſtoning of St. Stephen," are alſo after Carracci. "Jeſus Chriſt at the Houſe of Martha and Mary," after Dominichino. "The Paſſage of the Rhine by the French Army," after Vandermeulen. "The Voyage of Mary de Medicis to Pont-de-Le," after Rubens, for the Luxembourg gallery. "Winter," after the ſtatue which Girardin executed in marble, for the gardens of Verſailles. Seven plates containing different views of "The Tomb of Cardinal Richelieu, erected in the church of the Sorbonne. "Aſtronomy," an allegorical compoſition, after Michel Corneille, the ſon, an oval. "Venus bringing the Dictamnum to cure the Wound of Eneas," after Ch. de la Foſſe.

The ſix following are after Le Brun, *viz.* "The Entrance of Jeſus into Jeruſalem." "The bearing of the Croſs." "The Death of Hypolitus." "Hercules driving away the Stymphalides," an oval, in ſmall folio. "Hercules ſtriking the Hind with the brazen Feet," an upright. "The Conqueſt of Franche Comté, in 1674," a large allegorical engraving, with an arched top, and generally and juſtly eſteemed the maſter-piece of Simonneau. "Lot with his Daughters," and "The Nativity," are both after Noel Coypel, and the three following are after Anthony Coypel: "Chriſt diſputing among the Doctors," the original of which is in the cathedral of Notre Dame. An "Ecce Homo," and "The Triumph of Galatea." The two latter plates are etched by the painter, and finiſhed with the graver by Simonneau.

The following folio portraits by this artiſt have alſo conſiderable merit: Henrietta Maria, queen of Charles I. of England, after Vanderwerf. Charlotte Elizabeth, ducheſs dowager of Orleans, after Rigaud. Julius Hardouin Manſert, architect to the king, after Fr. de Troy. Charles François de Lomenie, of Brienne, biſhop of Coutances, after Dumee. Antoin François Ferrand, maſter of requeſts, after De Launay. Louis XIV., according to different painters, and at different periods of his life, a ſtring of medallions attached to a palm-tree. He alſo engraved two or three plates of the ſickening, or ridiculouſly refined, court flattery of Ant. Coypel, with portraits of the king, and Colbert d'Ormoy, *ſuperintendant* of the arts.

Simonneau had a ſon, Philip, whom he brought up to the profeſſion of engraving. His ſtyle was ſimilar, but his talents inferior to thoſe of his father, and he engraved but few plates.

Two large friezes, the one repreſenting "The Rape of the Sabines," the other, "The Peace between the Romans and the Sabines," after Julio Romano. "The Three Goddeſſes preparing for the Judgment of Paris," after Perin del Vaga, in folio. "Venus and Adonis," after Albano, and two plates for the Crozat collection, are all that are known of the works of Philip Simonneau.

Louis Simonneau, younger brother of Charles, was born at Orleans in 1656, and died at Paris in 1728. He ſeems to have taken as a model the works of Audran; and by combining the etching-needle with the graver, he has imparted an agreeable variety to his works. He drew with great correctneſs, as is more particularly obſervable in the extremities of his figures. Like his elder brother, he was a member of the Academy, and in reſpect to talents, was ſcarcely his inferior. The beſt hiſtorical works of Louis Simonneau are as follow, beginning with thoſe after Ant. Dieu, which are of the folio claſs: "The Bearing of the Croſs." "Jeſus Chriſt nailed to the Croſs." "Jeſus Chriſt dead on the Croſs." Theſe three plates conſtitute part of a ſeries of twelve, the reſt of which are engraven by J. Audran. "St. Catherine." "The Aſſumption of the Virgin," after the cieling painted by Le Brun in the ſeminary of St. Sulpice. Thoſe which follow are after the ſame maſter, and are alſo in folio. "The Four Times of the Day." "The Four Seaſons," on the cieling of the Chateau de Vaux le Vicomte. "The Cieling of the Pavilion of Aurora, in the Gardens of Sceaux," in four plates, and "The Nymph of Sceaux." "Suſanna at the Bath ſurpriſed by the Elders," after Ant. Coypel, and "Jeſus at the Houſe of Martha and Mary," both in folio, after Ant. Coypel.

The beſt portraits by this artiſt are thoſe of Hyacinthe Serroni, firſt archbiſhop of Albi, in quarto. Antoine Arnauld, a celebrated theologian, after Ph. D. Champagne, in folio. Antoine le Maitre, advocate of the parliament, after the ſame. Martin Charmois, counſellor of ſtate, director of the royal academy of painting and ſculpture, after Seb. Bourdon, 1706, in folio.

Nicholas de Larmeſſin, the father, was born at Paris about 1640. Very little is known reſpecting the life of this artiſt, except that he engraved a great number of portraits of the illuſtrious men of France, and other countries. His ſtyle of engraving was far from diſagreeable, and he may juſtly be claſſed with the beſt engravers of the ſecond rank. The graver was the ſole inſtrument of his art, and he ſometimes marked his plates with the monogram which will be found in our plate of thoſe of the French ſchool. His beſt portraits are thoſe of Philippe de Bourbon, duke d'Orleans, brother of Louis XIV. Henrietta Stuard, ducheſs d'Orleans, conſort of Philippe. Charles XI. of Sweden. Henry-Julius de Bourbon, duke d'Enguien. Godefroy, count d'Eſtrade, marſhal of France. Gabriel Nicolas de la Reynie. Claude Felicite of Auſtria, conſort of the emperor Leopold I. Louiſa-Frances, ducheſs de la Valliere, in the dreſs of a carmelite nun. Theſe are all of the quarto claſs; the following are in folio; Maximilian-Henry, archbiſhop of Cologne. Balthaſar Moretus. Paul Manuce, a learned Italian. Laurent Coſter de Harlem, the pretended inventor of printing. Jean Guttemberg de Mayence, the real inventor of printing. The laſt is engraved without any croſs-hatchings, in the manner of Mellan.

Nicholas de Larmeſſin, the ſon, was born at Paris in 1684, and died in the ſame city in 1755, with the title of engraver to the king. He was the pupil of his father, and early diſplayed the greateſt induſtry in engraving portraits as well as hiſtorical ſubjects. This artiſt had acquired great reputation for the prints he had executed for the collection of Crozat, but afterwards, borne away by the torrent of faſhion, he only employed himſelf in engraving ſuch works as thoſe of Watteau, Lancret, Boucher, &c. His ſtyle of engraving, which conſiſted partly of etching, but chiefly of the work of the graver, poſſeſſed firmneſs and ſolidity, but his drawing was not correct.

The celebrated Schmidt of Berlin was the pupil of Larmeſſin, and engraved ſeveral ſubjects after Lancret, which are marked with the name of his maſter. The prints bearing the name of Schmidt are extremely ſcarce.

Larmeſſin's beſt engravings are thoſe which were done, chiefly after Raphael, for the Crozat collection, and which are entitled as follow:

Portraits of Raphael, with that of Pontormo. Cardinal Pole, with a long beard, ſeated in an arm-chair, from a picture attributed by ſome to Raphael, and by others to Sebaſtian

baſtian del Piombo. Frederic Carondelet, archdeacon of Bitento; this plate was engraven from a drawing in the poſſeſſion of M. de Crozat, which was copied from a picture in the poſſeſſion of the duke of Grafton, and the plate was afterwards worked upon in England, (preſumptively after the original picture,) by ſir N. Dorigny. "St. Michael overcoming the Devil." Another of the ſame ſubject, differently treated. "St. George encountering the Dragon." "St. John the Evangeliſt." "The Holy Family." "The Madonna with the Infant Chriſt aſleep on her Lap." "Chriſt bearing his Croſs," a very large print, from a very celebrated picture of this maſter, and "The Viſion of Ezekiel," a middle-ſized, upright folio. The portrait of Adam de Vignancourt, grand maſter of Malta, after Michael Angelo du Carravaggio; and that of a comedian in the ſervice of the duke of Mantua, after Dominico Feti, were alſo engraven for the Crozat collection.

The beſt of our artiſt's engravings after French painters are of the folio claſs, and are entitled "Louis XIV. conferring the Blue Ribbon on the Duke de Bourgogne, Father of Louis XV., from a Picture in the Cabinet of M. Julienne." "Cytheræ Inſulæ," and "Pagi Sponſa," after Watteau.

After Lancret he has engraven, "A Village Coquette." "The Play of Bull-leap." "The Gaſcon puniſhed." A ſet of four plates of "The Four Ages of Man," characterized by the amuſements proper for each period; and "The Four Seaſons," characterized by the occupations proper for each ſeaſon.

The beſt of his prints after Boucher, are, A monument to the memory of John Tillotſon. "The River Scamander." "The Amourous Courtezan." "A Nobleman," and "The Calendar of old Men," the four latter taken from the tales of Fontaine.

The portraits by this artiſt, which are held in moſt eſteem, are thoſe of Guillaume Couſtou, ſculptor in ordinary to the king, painted by Jean de Lien, and engraven by N. Larmeſſin the ſon, for his reception into the academy in 1730. Claude Hallé, painter to the king, painted by Le Gros, another reception piece. Philippe Vleughel, a Flemiſh painter, painted by Ch. de Champagne. Louis XV. on horſeback, after J. B. Vanloo and C. Parrocel. Louis XV. on foot, after J. B. Vanloo, and C. de Parrocel. Maria Leizincka, conſort of Louis XV. after the ſame. Maria-Joſephine of Saxony, dauphineſs of France, after the ſame. Charles-Henri de Lorraine, after Ranc. Woldemar de Lowendal, marſhal of France, after Boucher. Mademoiſelle Sallé dancing, after Lancret, all in folio.

M. G. Tournier was born at Toulouſe about the year 1640. He was the diſciple of Moiſe Valentin, and painted ſeveral ſubjects for the churches of his native city.

He etched ſeveral landſcapes after Salvator Roſa, ſome Madonnas after Guido, a few trophies after Polidore de Carravaggio, and ſeveral vaſes after Charles Errard. Strutt has confounded this artiſt with Robert Tourniere, who was a ſkilful portrait painter, and a native of Caen.

Jaques Grignon was born in France, but in what part is uncertain, ſome time in the year 1640, or thereabout, and flouriſhed till toward the cloſe of the century. The greater number, and beſt executed, of his engravings, are portraits, which are entirely the work of the graver, and are eſteemed for clearneſs, neatneſs, and truth of repreſentation. His hiſtorical ſubjects being dark, heavy, without much effect, and incorrectly drawn, are leſs worthy of notice.

The beſt portraits by Grignon are thoſe of François-Marie Rhima, an eccleſiaſtic, in ſmall folio, and of the oval form. Pierre Barbareau, doctor in theology, after Champagne. Jacques Caur, ſeigneur de St. Fargeau, ſuperintendant of the finances under Charles VII., in 1450. Jehan Bureau, a powerful nobleman, chevalier and mayor of Bourdeaux, chamberlain to Charles VII. and Louis XI., and maſter of the French artillery, all in folio.

Grignon alſo engraved ſeveral plates for a work in ſmall folio, entitled, "Les Tableaux de la Penitence," after the deſigns of Chauveau.

Charles de la Haye was born at Fontainebleau in 1641. He viſited Italy when he was very young, reſided there a conſiderable time, and in conjunction with Bloemaert, Spierre, Blondeau, and others, engraved the paintings of Pietro da Cortona, in the Pitti palace at Florence. His ſtyle of engraving ſomewhat reſembles that of Bloemart. His croſs-hatchings are thrown nearly at right angles over his firſt courſes of lines in a manner at which modern taſte revolts; and his chiaro-ſcuro is deficient in harmony; but his drawing of the naked is tolerably correct, which is certainly a cardinal requiſite, more eſpecially in engraving after the maſters of the Italian ſchools.

The beſt engravings of de la Haye are of the folio claſs, and their ſubjects

"The Virgin with the infant Jeſus on her Knees, who is diſtributing Palms to St. Catherine and other holy Martyrs," after Ciro Ferri. "The Virgin and Child appearing to St. Philip Neri," a large upright, after the ſame maſter. "Coriolanus refuſing to ſee the Roman Ambaſſadors, on being exiled from Rome," after the ſame. "The Grecian Philoſophers converſing in the Garden of Academus," J. F. Romanelli pinx., a fine plate, and probably his very beſt performance.

Jean Dolivan was born at Saragoſſa in 1641. He ſettled at Paris, and was chiefly employed in engraving ornaments, and decorations of various kinds. His prints may be claſſed with thoſe of Chauveau and le Pautre; but he had a leſs fertile genius than the latter. He engraved ſeveral works in conjunction with different artiſts, and among others, the ſeries termed, the little Conqueſts of Louis XIV. ſome of the plates for Berain's ornaments of the royal tapeſtries, one of the cielings for Perault's cabinet des Beaux Artes. "The Strangling of the Grand Vizier." "Funeral Decorations of the Chapel of Condé, at the Houſe of the Jeſuits." "Subject of Grief for the Divine Service at the Chapel of Condé." "Mauſoleum for the Funeral Obſequies of Maria de Guiſe d'Orleans, Queen of Spain, in 1695," all in folio, and after Berain.

Gerard Scotin was born at Goneſſe, near Paris, in 1642, and flouriſhed towards the end of the ſeventeenth century. He was the pupil of François Poilly, and handled the graver with much neatneſs; but his execution was not equally mellow with that of his maſter, nor was his drawing of the naked equally correct.

Of Gerard Scotin, the younger, who viſited England, and was a ſuperior artiſt to his father, we have ſpoken in our account of the *Origin and Progreſs of* ENGLISH *Engraving*.

The beſt works of Gerard Scotin the elder, are of the folio claſs, and their ſubjects, "The Marriage of St. Catherine," after Alex. Veroneſe. "The Magdalen receiving Communion from Angels," after Dominichino. "A rural Life," after Dominico Feti, an upright. "The Circumciſion," inſcribed "Vocatum eſt Jeſus," after P. Mignard. "The Baptiſm of Jeſus Chriſt," inſcribed "hic eſt filius," after the ſame painter. "Preſentation of the Infant Jeſus in the Temple," after Ch. le Brun. (B. Audran has engraven the ſame ſubject.) "Monumentum marmoreum Caſtellanorum," after the marble of Girardon. "The Siege of Courtray,"

tray," after Vandermeulen, the landſcape of which is engraven by Baudouin, the figures by Scotin.

François Spierre was born at Nancy in the year 1643. He ſtudied at Paris, in the ſchool of F. de Poilly, and ſoon attained a ſuperiority even over that able maſter. He was a man of a philoſophical turn of mind, great profeſſional induſtry, and extraordinary talent in his art. From Paris he travelled to Italy, in queſt of further improvement, where he remained a conſiderable time, and where his beſt works were performed. On his return from Italy he was taken ill at Marſeilles, and died there at the early age of thirty-three, according to Strutt, though, according to the French writers, he was thirty-eight, to the great regret of all who poſſeſſed the leaſt taſte for the art of engraving.

His beſt works are held in great requeſt among connoiſſeurs, and are worthy of great praiſe. Strutt ſays of him very truly, that he did not imitate the ſtyle of his tutor, though he worked entirely with the graver, which inſtrument he handled with great facility. He gave more play to the ſtrokes, and produced an effect more ſoft and pictureſque. But his ſtyle was ſo various upon different occaſions, that we may add the ſubſtance of what Watelet has ſaid of him, without overcharging the profeſſional character of our artiſt.

When he arrived at Rome, he found Cornelius Bloemart, whoſe ſtyle he occaſionally imitated, in the full vigour of his powers, and the meridian of his reputation. But Bloemart and de Poilly each confined himſelf to one ſtyle, whereas Spierre could vary his at pleaſure; he ſometimes employed only a ſingle courſe of lines, which he managed with a degree of eaſe and freedom, ſuperior to that of Mellan, ſo that he may be ſaid to have beaten three of the greateſt hiſtorical engravers of the age, each at his own weapons. Sometimes the connoiſſeur is ſurpriſed by the boldneſs and grandeur of his execution, and at others charmed with its delicacy and ſweetneſs; and he has an occaſional playfulneſs which may vie with that of etching, even from the hand of a maſter. Yet the preſent writer has ſeen prints from the graver of Spierre, or at leaſt inſcribed with his name, that are by no means worthy of theſe encomiums.

His abilities were not confined to engraving. He ſometimes painted hiſtory and allegory in a ſtyle which appears formed upon that of Pietro da Cortona, and ſometimes portraits. His portrait of count Laurent de Marſciano, which he engraved from a picture by himſelf, is remarkable for its harmonized variety of tints, though no part of the print be puſhed to the degree of blackneſs which has often been deemed indiſpenſable to a vigorous chiaro-ſcuro.

Conſidering the ſhort period of his life, his engravings are not few, and not many lives have been more completely filled with various and meritorious exertion. We begin our detail of the ſubjects of his plates, with thoſe which he engraved, after the pictures of the celebrated Italian maſters.

"The Virgin ſuckling the Infant Saviour," a circle, or ſhort oval, after Correggio. The earlieſt, and moſt rare proofs of this admirable engraving, are taken before drapery was introduced to cover the nudity of the infant, and are alſo without certain ſmall trees which are ſeen in the ſubſequent impreſſions to the left of the virgin; and theſe are ſo valuable, that at the ſale of M. Mariette, one of them brought five hundred livres.

"St. Michael encountering the Dragon," (a frontiſpiece to the Roman Miſſal;) this with the four following are all in folio, and all after Pietro da Cortona. "The miraculous Conception," engraved for the Miſſal of pope Alexander VII. "St. Martin before the Virgin, and the Infant Jeſus, who holds a Lily in one Hand, and in the other a Palm." "The Architect of Alexander VIII. preſenting to that Pope a Plan of Mount Athos, with his propoſed Improvements." "Cyrus refuſing to ſee Panthea, (his Captive,)" after a painting in the Pitti palace at Florence.

After Ciro-Ferri, Spierre has engraven the four following ſubjects, in folio. "The Circumciſion," for the Miſſal of pope Alexander VII. "Pallas in the Clouds, in a Chariot drawn by a Lion and a Lioneſs, with Jupiter on high, and a Philoſopher below." "A bird-hunting during Harveſt," and "The Innocence of Criſpe."

And from the pictures of Bernini, "A Madonna with her Hands croſſed," a circle in 4to. "St. John preaching in the Deſart." "The Miracle of the Loaves and Fiſhes." "Chriſt on the Croſs, ſuſpended over a Sea of Blood," which ſeems to have flowed from his own wounds; a ſingular performance executed without any croſs hatchings, the firſt impreſſions of which are diſtinguiſhed by having been printed before certain heads of cherubs were introduced; and "The Chain of St. Peter," (a large print engraved on two plates.) Theſe are all of the folio claſs, and the following are either painted from nature, or invented by Spierre himſelf.

Innocent XI. Odeſcalchi, ſovereign Pontiff, in 4to. The Grand duke of Tuſcany, engraven in 1659, in folio. Laurent count de Marſciano, in folio, a capital plate, of which we have already ſpoken. Medallion of Alexander VII. borne high in the air by a genius, while underneath is ſeen a Hercules entering the gardens of the Heſperides, and the three daughters of Heſperus preſenting him with oranges. An allegory on the culture of orange-trees, under the pontificate of that pope, in folio. "Mars and Minerva preſiding over the Culture of Roſes," with which three nymphs are occupied. "An Allegory on the Faculties of the ſoul," in folio, a diſtinguiſhed piece of our artiſt, and, which ſerves to ſhew his philoſophical turn of mind.

Jean Louis Roullet was born at Arles, in Provence, in the year 1643, and died at Paris in 1699. He learned the firſt principles of drawing and engraving from Jean L'enfant, and completed his ſtudies in the ſchool of F de Poilly, whoſe manner of engraving he adopted with great ſucceſs. Quitting the ſchool of de Poilly, he went to Italy, where he remained ten years, and where his merit recommended him to the favourable notice of Ciro-Ferri, and other celebrated artiſts, to whom he was alſo endeared by his amiable perſonal qualities.

Roullet handled the graver with great freedom and facility, and drew the human figure correctly; he therefore ranks high among the engravers of France. His large print of the three Maries at the ſepulchre, after A. Carracci, which according to Florent le Compte he engraved during his reſidence at Naples, is much admired for correctneſs of outline, force of chiaro-ſcuro, beauty of engraving, and the accuracy with which the expreſſion of the original is transfuſed. The ſubjects of his other productions are as follow, beginning with the hiſtorical:

A piece named "St. Claire." Here the infant Jeſus is ſeen on the knees of his mother, placing his right hand on the tabernacle, accompanied by St. Joſeph, after Aug. Carracci. (Several artiſts have engraven from the ſame picture.)

"The Virgin holding the Infant Jeſus, and a Book," after the ſame. "The Madonna, and Infant Jeſus, who embraces his Mother," after J. Lanfranc. Two of the angles of the dome of the church of the Jeſuits at Naples, on which are repreſented the Evangeliſts, St. Matthew, and St. Luke; the two others, St. Mark and St. John, are engraven by Fr. Louvemont, after J. Lanfranc. "A Nun receiving a Buckler from Heaven," dedicated to the biſhop of Paderborn, with his portrait. Ciro Ferri inv. "Jupiter ordering the Shield of Perſeus to be forged," dedicated to the

the emperor Leopold, a large ſubject executed by the ſame artiſts, in two plates. "Hercules preſenting to Jupiter the Monſters whom he had overcome," dedicated to pope Innocent XI. a ſubject executed by the ſame artiſts, engraven at Rome in 1678. "Perſeus cutting off the Head of Meduſa," and "Perſeus ſlaying the Sea Monſter," two plates in ſmall folio. "The Viſitation of St. Elizabeth," dedicated to the dauphineſs, after P. Mignard. "The Virgin with the Infant Jeſus in her Arms, who holds a Bunch of Grapes," a piece known under the name of "la Vierge au Raiſin," dedicated to Madame de Maintenon, after the ſame. The above are all in folio. "David preſenting the Head and Sword of Goliah to Saul," after Joſ. Parrocel, in 4to.

The beſt portraits by Roullet, are thoſe of Francis de Poilly, engraver to the king, inſcribed Fr. de Poilly ad vivum del. 1699, in ſmall folio. Catherine Touchelle, wife of Hilaire Clement, procureur to the parliament, after Cotelle. Aſcanius Philamarinus, cardinal archbiſhop of Naples, Fr. de Marcu pinx. J. L. Roullet del. et ſc. Neapoli. "Jacques-Louis, marquis of Beringhen, firſt equerry to the king, after P. Mignard, in folio. Jean-Baptiſte Lully, ſecretary to the king, &c. after P. Mignard. Jean-Chaillon de Thoiſy, doctor of the Sorbonne, after C. Gerardin. Edward Colbert Cher, marquis Villacerf, ſuperintendant of buildings, &c. by J. L. Roullet of Arles, 1698, an able engraving in imitation of bas relief. Camille le Tellier de Louvais, abbot of Bourdeaux, librarian to the king, after Nic. de Largilliere. Louis XIV. in regimentals, a three-quarter figure, after the ſame, all in folio.

Benoit Frajat was born at Lyons in 1646. He learned the elements of his art under Guillaume Chateau, whom he accompanied into Italy, and whom he very ſoon ſurpaſſed in the mellowneſs, neatneſs, and freedom of his engravings, though not in other reſpects.

Having ſettled at Rome, Frajat eſpouſed the daughter of the celebrated landſcape painter François Grimaldi, better known by the appellation of the Bologneſe. He engraved, after the moſt celebrated Italian maſters, a great number of plates, among which the following, which are of the folio claſs, are held in moſt eſteem.

"The Holy Family," after Albano, one of his earlier engravings, done under the direction of Chateau. Another "Holy Family," after Pietro da Cortona. St. John is here preſenting a croſs to the infant Saviour. "The Marriage, or the Coronation of St. Catharine," after Aug. Carracci, a large plate of the upright form. "The Holy Family," and "The Temptation of St. Anthony," both after Annibal Caracci. "The Death of St. Jerome," from Dominichino, another large upright. "St. Francis Xavier expiring, contemplated by Groups of Angels in the Clouds," after J. B. Gaulli. "Our Saviour baptized in the Waters of Jordan," after Carlo Maratti. "St. Bridget ſitting in the Clouds, triumphant over Envy, and venerated by Sages," after B. Lutti, engraven in 1707. "The Courſe of Atalanta," after P. Luccatelli.

The beſt portraits by this artiſt are alſo in folio, and are thoſe of Cardinal Frederic Coccia; Cardinal Cornaro; Cardinal Thomas Ferrari; Dom Cœleſtinus, cardinal Sfrondatus, all after the pictures of L. David.

The biography of the family of the Bonnarts is in a confuſed ſtate in all the books that we have conſulted, which, as they were mere men of mediocrity, will probably be the leſs regretted. It would appear that the brothers Robert and Nicholas were born at Paris about the middle of the 16th century, and perhaps alſo John Bonnart the elder, who engraved figures a-la-mode, and Italian comedians a-la-groteſque, with fifty-ſix plates of the coſtume of the different nations of the earth, all in folio, and after his own deſigns.

He who ſigns his name Joan Bonnart, jun. is ſuppoſed to have been the ſon of the former, and by him there is a ſpirited and free etching of a cieling adorned with poetical ſubjects, and publiſhed in Perault's Cabinet des Beaux Artes.

The beſt works of Robert and Nicholas are as follow, all of them being of the folio claſs:

Portrait of Louis XIV., Robert Bonnart fecit. Portrait of Louis, Dauphin, ſon of Louis XIV. Idem fec. "Valenciennes taken by Aſſault, and ſaved from Pillage by the Clemency of the King, 1677," after F. Vandermeulen, engraven by R. Bonnart. "The King taking Poſſeſſion of the Citadel, after the Capture of Cambray, 1677," "Arrival of the King before Douay, which he cauſes to be inveſted by his Cavalry," Id. ſc. "Entrance of the Queen into the City of Arras," Id. ſc. in two plates, all after Vandermeulen, and engraved in a coarſe ſtyle.

Pierre Giffart is another mediocre artiſt, who, however, ſubſcribes himſelf Sculptor Regius. He was born in Paris in the year 1648, and died there in 1723. What talent he poſſeſſed was chiefly exerciſed on portraits, medals, and ornaments, among which the following are held in moſt eſteem:

Marie-Anne Victoire of Bavaria, dauphineſs of France; below is repreſented the birth of the duke de Bourgogne, in folio. Frances d'Aubigné, marchioneſs de Monteſpan; executed by P. Giffart, engraver to the king, in folio. Philippe I. ſon of Thomas XIII. count of Savoy. J. D. Lange del. P. Giffart Sculptor Regius, Pariſiis, in ſmall folio. Odoard, ſon of Amadeus XV. count of Savoy. Id. del. id. ſc. Aymon, ſon of Amadeus XVI. count of Savoy. Id. del. id. ſc. Louis, ſon of Amadeus VIII. ſecond duke of Savoy. Id. del. id. ſc. all of the ſame ſmall folio ſize. Collection of medals of the princes of the Lower Empire. Series of friezes, of cornices, tapeſtries for an altar, and three chandeliers; five plates engraven by Giffart and Dolivart, after Berain, in folio. Frontiſpiece for the introduction to P. Violier's Geography, after S. Le Clerc, in quarto. Frontiſpiece to the Critical Hiſtory of Superſtitious Practices, after the ſame.

Of the family of Parrocel much more may with juſtice be ſaid; for both as painters and engravers they have ſome claims to be conſidered as men of genius. Joſeph was born at Brignolis, in Provence, in the year 1648, and died at Paris in 1704. He viſited Rome, and ſtudied there under Bourguignon the battle painter, with whom he formed an intimate friendſhip. He was remarkable for the energy and expreſſion of courage which he imparted to his warriors, and has been heard to obſerve of thoſe of Vandermeulen "ne ſavoit pas tuer ſon homme."

The following etchings of Joſ. Parrocel are from his own compoſitions: they are of the quarto ſize, and are believed to include the whole of his works on copper:

A ſet of four plates of the four times of the day, *viz.* "Aurora, or the Camp;" "Mid-day, or the Halt;" "Evening, or the Battle;" "Night, the Field of Battle." A ſeries of forty-eight plates from the life of Chriſt, and four other battle pieces.

Charles Parrocel, the ſon of Joſeph, was born at Paris A.D. 1689, and died in the ſame city in 1752. He dedicated his attention to the ſame ſpecies of art in which his father excelled, by whom he was inſtructed, and whom he had the misfortune to loſe at the age of ſixteen: he was

then

then placed under the tuition of La Foſſe, after which he viſited Italy, and remained there ſeveral years.

On his return to his native country with the reputation of an excellent painter of battles, he was attached to the French cavalry, in order that he might enjoy the beſt opportunities of ſtudying ſuch military ſubjects as occurred; and he was alſo ſelected to paint the conqueſts of Louis XV.

He handled both the graver and etching-needle with facility; yet his works are on the whole inferior to thoſe of his father. A ſeries of plates of cavalry and infantry, after his own deſigns, are executed with conſiderable ſpirit.

Etienne Parrocel was the nephew of Charles, and was born in Paris ſomewhere about the year 1720. He alſo painted, etched, and handled the graver. The following ſubjects from his hand are executed in a bold and free ſtyle.

"The Triumph of Mordecai," after J. F. de Troy. "The Triumph of Bacchus and Ariadne," after P. Subleyras, both large folios. A bacchanalian ſubject in quarto, from a compoſition of his own.

Elizabeth Sophie Cheron, (ſubſequently Madame le Hay,) a lady celebrated for the extenſiveneſs of her acquirements and her talents in the fine arts, was born in the year 1648, and was the daughter of Henry Cheron, an enamel painter of Paris, under whoſe inſtruction ſhe made rapid progreſs in the arts of deſign. She was patronized by Le Brun, and received with flattering diſtinction by the Royal Academy, in the year 1676. At the age of ſixty ſhe married M. le Hay of the royal engineers, and died in her native city at the age of ſixty-three.

The preſent writer has not ſeen her engravings, and from the vague manner in which they are ſpoken of by her French biographers, cannot be certain whether the three following ſubjects are copied from antique gems, or deſigned by Madam Cheron with the view to their being engraved on gems, but moſt probably the former. They were, however, etched by herſelf, of the quarto ſize. "Bacchus and Ariadne;" "Mars and Venus;" and "Night ſhedding her Poppies."

She alſo engraved a "Deſcent from the Croſs," in folio, from a model by the abbé Zumbo. The plate is etched, and afterward finiſhed with the graver in a ſtyle that does credit to the powers of the artiſt.

Her remaining prints are a group of ſaints after Raphael, and a drawing-book containing thirty-ſix plates from deſigns of her own.

Louis Cheron, born at Paris in the year 1660, was brother to Elizabeth Sophia. He went to Italy, and remained there eighteen years, partly ſupported by the bounty of his ſiſter. He compoſed with facility, and drew rather correctly than gracefully. In his religious principles he was a Calviniſt, and the perſecutions of that ſect, which took place ſoon after his return to his native country, obliged him to ſeek refuge in England, where he was employed by the duke of Montague, and where he died at the age of fifty-three.

The following prints from his hand diſplay taſte and ability: they are of the folio ſize, and from his own compoſitions.

"St. Peter healing the lame Man at the Gate of the Temple;" "The Death of Ananias and Sapphira;" "St. Philip baptizing the Eunuch of Queen Candace;" and "Hercules reſting from his Labours." We ſhould not omit twenty-three plates which he engraved for his ſiſter's French verſion of the pſalms of David.

Nicolas Habert was born at Paris about 1650. He engraved almoſt conſtantly for the bookſellers, beſides executing a great number of portraits of French men of letters and other celebrated characters of the laſt century. Habert was tolerably well inſtructed in the mechaniſm of his art, which is all the praiſe which can in juſtice be awarded him. The beſt of his engravings are the following portraits.

Louis Maimbourg, a celebrated Jeſuit and author, engraven after life by N. Habert, 1686. Jean Baptiſte Santeuil, canon of St. Victor, 1686. Corneille Janſénius, biſhop of Ipre, doctor in theology at Louvain, after Champagne. Felix Vialart, biſhop of Chalons. Maria Louiſa of Orleans, daughter of Monſieur, queen of Spain. John Milton, the celebrated Engliſh poet. Thomas Parr, a celebrated Engliſh centenarian, all in folio.

Jean and Louis Creſpy, or Crepy, father and ſon, were both born in Paris, the former about the middle of the ſeventeenth century, the latter in the year 1680. Strutt ſpeaks of their abilities rather worſe than they deſerve, though neither of them merit much praiſe, nor other notice from us than the taſk of mentioning their principal works, which are as follow, and which, excepting their portraits, are of the folio claſs.

"Mary Magdalen," Crepy inv. et fecit. "The Manger," here the Infant Jeſus is ſeen ſleeping on ſtraw, and adored by two angels, after Albano. This is a print of ſome merit, and probably the beſt work of the elder Crepy. "The Deſcent from the Croſs," after Carlo Cignani. "A Holy Family, or St. Benedicite," after le Brun. "The Preſentation of the Infant Jeſus in the Temple," after the ſame, in ſmall folio. "The Rehearſer of amatory Speeches," after Watteau, engraven by Crepy the ſon, in folio.

The following portraits are alſo by theſe *artizans*, for artiſts they may ſcarcely be called, and are neatly finiſhed. Maria-Adelaide, princeſs of Piedmont, oval, in 4to. The chancellor d'Agueſſeau, in 4to. R. P. Allizi, oval, in 4to. The biſhop of Caillebot, 4to. Mahomet Effendi, ambaſſador to France, in 8vo. Antoine Houdart de la Motte, in 8vo. Antoine Watteau, in 8vo. The duke of Marlborough, in 8vo.

From the inſipidity of Habert and the Crepys, attention rebounds to the noble daring of Raymond la Fage. He was born at Thouloufe, or according to ſome writers at Liſle in the Abigeois, in the year 1654. Strutt does not often riſe to the tone of energy with which he writes of this man of genius, and we therefore heſitate not to adopt his words in preference to our own, or the tame prolixity of Huber and Roſt. La Fage "never had any maſter, but following the dictates of his own genius applied himſelf to drawing; and his works ſufficiently teſtify the ſurprizing progreſs he made in that art. His drawings are compoſitions of his own, chiefly outlines and ſlight ſketches made with a pen, but executed in a moſt maſterly ſtyle. The actions of his figures are ſpirited, bold, graceful, or elegant, as the ſubject required. His groups are finely contraſted; and frequently, without the aſſiſtance of ſhadow, he has contrived to detach them from each other, in ſuch a manner that the ſubject is by no means confuſed, or the effect diſagreeable. Certainly no man ever poſſeſſed greater fertility of invention, or facility of execution, and though he has ſometimes borrowed whole figures from the works of other maſters, and engrafted them in his own, yet he ſo well adapted thoſe of his own invention, to the ſtyle and action of thoſe he borrowed, that the plagiariſm ſeems rather to do him honour, than tend to his diſcredit. He reſided ſome time in Italy, and when he ſhewed his deſigns at Rome, they aſtoniſhed every one who beheld them.

Going one day to viſit Carlo Maratti he found that artiſt at work. Maratti, pleaſed to ſee him, received him very affectionately,

affectionately, and riſing up from his place, offered to put his palette and pencils into the hands of his gueſt, but La Fage refuſed, declaring that he did not underſtand the management of the pencil. 'I am very happy' (replied Maratte) 'to find that is the caſe, for had you known how to paint, as well as you do how to draw, I ſhould have been the firſt to abandon the art, becauſe you could have filled my place ſo much better.' He led a looſe, depraved life, which his repeated debaucheries put an end to, A.D. 1690; he being only at the age of forty-two.

It is here to be obſerved that Strutt dates his birth in the year 1648, and the French writers in 1654; now if he was born in 1654, and died in 1690, he could only have been thirty-ſix years of age at the time of his death.

La Fage etched a conſiderable number of ſmall plates from his own compoſitions, which are marked with the eaſe and energy of a maſter, particularly his fall of the angels, and his Bacchanalian feſtivals and proceſſions. The following, which are in folio, are among his moſt eſteemed productions:

A pair "Jupiter and Semele," and "Juno and Eolus," of the frieze form; another pair of "Children Fiſhing," and a "Dance by Children;" a large plate of a Bacchanalian ſubject, and two large uprights of "The Brazen Serpent," and "The Fall of the Angels."

François Andriot, or Handriot, was born at Paris about 1655. He engraved both in France, and during his reſidence in Italy, various ſubjects after ſeveral celebrated painters of thoſe countries. His ſtyle reſembled that of Fr. de Poilly, but his productions were inferior in point of effect to thoſe of that celebrated artiſt. His prints are, however, ſought after by ſome connoiſſeurs, on account of the pictures of the great maſters from which he engraved. His beſt works are all in folio, and their ſubjects as follow:

"The Virgin ſitting, holding on her Knees the Infant Jeſus, to whom the little St. John preſents a Roſe," after Raphael, an oval. "The Virgin ſuckling the Infant Jeſus, attended by an Angel," after Guido, an oval. "A Magdalen," after the ſame. "Chriſt crowned with Thorns," after Ann. Carracci, without the name of the painter, oval. "Chriſt ſcoffed at, and crowned with Thorns," after Dominichino, oval. "The Madonna and Child, with St. Michael and St. Marguerite," anonymous. "The good Samaritan," after Pouſſin, a large plate. "The Incredulity of St. Thomas," after Le Sueur, a large plate. "Eſther before king Ahaſuerus," after Sim. Guillebault. "The Wedding at Cana," after the ſame. "Pope St. Gregory kneeling before the Altar in a Chapel, and three Eccleſiaſtics ſtanding on the Clouds." "Jean Everhard, cardinal Niclard," after Jonas de la Bonde, engraven in 1672, and ſome of the ſtatues publiſhed at Rome by Roſſi in 1691.

Jean-Baptiſte Nollen, or Nolen, was born at Paris in 1655. He was one of the beſt pupils of N. de Poilly, and was extremely expert at the mechanical part of his art. After viſiting Rome, he returned and ſettled in his own country. He engraved ſeveral of the large folio prints, entitled "Les Vües, Plans, Coupes, et Elevations du Chateau de Verſailles." "The Miracle of the Loaves and Fiſhes," after Raphael, and ſeveral plates from Carracci, Pouſſin, and other maſters.

John Mariette was a native of France, and ſtudied painting under his brother-in-law J. B. Corneille, but by the advice of Le Brun quitted that purſuit, and applied himſelf to deſigning and engraving. He alſo carried on a conſiderable commerce in prints. Some of his compoſitions poſſeſs conſiderable merit. The heads of his figures are often well characterized; his drawing, though mannered, is not incorrect. He worked both with the graver and etching needle, and his ſtyle of engraving is coarſe and ſlight. He died at Paris in the year 1742. The principal productions of Mariette are as follow: "Staniſlaus-John Jablonowſki," in folio. "St. Peter delivered out of Priſon," after Dominichino, in folio. "Jeſus Chriſt in the Deſart, ſerved by Angels," after Le Brun, in folio. "Deſcent from the Croſs," after the ſame, in folio. "The finding of Moſes," after Pouſſin, in folio. "Two Nymphs ſeated near a Fountain, in which Narciſſus is ſporting," a beautiful landſcape, in folio. "Joſeph revealing himſelf to his brethren," after M. Corneille, in folio. "The Cure of the Paralytics," after the ſame, in folio. "St. Louis receiving the Holy Viaticum," after J. B. Corneille, in folio. "St. Louis received into Heaven," after the ſame.

J. P. Mariette, the celebrated connoiſſeur, was the ſon of John, and etched a few plates after Guerchino, Carracci, and Perin del Vagu. He was born at Paris in 1694, died there in 1774, and the memorable ſale of his cabinet took place in the year 1775.

Benoit Thibouſt was born at Chartres A.D. 1660, but reſided for the greater part of his life at Rome; yet he may be reckoned to have been of the ſchool of Mellan. He engraved legendary and ſuperſtitious ſubjects in the ſtyle of that artiſt, though without attaining his excellence, of which the principal are:

A ſet of thirty-four plates after F. B. Gaetano, for "Vita beati Turribii, Archiepiſcopi Limani in Indiis," publiſhed in 4to. at Rome A.D. 1679. "St. Thereſa in an Extacy on the Clouds, while an Angel is preparing to pierce her Boſom with a flaming Dart," after Bernini, in folio. "The Statue of St. Bibiene in a Niche," after the ſame, in folio. "St. Thomas Aquinas," after Hyacinthe Calandrucci, engraven in 1690, in folio. "St. Roſe kneeling before the Virgin," after Ant. Baldi, in folio. "Martyrdom of St. Peter d'Arbues," after the ſame, in folio. "St. Peter of Alcantara in the Clouds, viewing the Croſs," after the ſame, in 4to. Portrait of John Baptiſte Coccinus, and "The Crucifixion," after Scipio Gaetano, both in folio.

Jean Baptiſte Boyer, marquis of Aiguilles, procureur general of the parliament of Aix, in Provence, was born at Aix in 1660, and died in his natal city about the middle of the laſt century. Connected by the moſt intimate ties of friendſhip with the celebrated Puget, he acquired, in his intercourſe with that ſkilful artiſt, a taſte for the fine arts, and thus became a connoiſſeur, deſigner, painter, and engraver.

During a journey, which he undertook, to Italy, and after his return to Aix, he formed a collection of paintings, ſculptures, drawings and prints, in which he took great delight. He cauſed this cabinet to be engraven, and it was publiſhed about the commencement of the laſt century; but not ſatisfied with the firſt edition, he brought an artiſt from Antwerp, Jaques Coelmans, who engraved anew the whole cabinet, which was publiſhed in 1744.

Theſe plates having afterwards fallen into the poſſeſſion of Pierre François Baſſan, he ſold them as the collection of Crozat.

The firſt edition of this collection contains ſix ſubjects engraved by the marquis himſelf; wherefore he is reckoned among the engravers of the French ſchool. The impreſſions of theſe plates, of which the ſubjects are as follow, are now become very rare, from the plates having been loſt or deſtroyed.

"The Marriage of St. Catherine," from And. del Sarto. Two figures of Jeſus Chriſt when young (engraved on the

ſame plate). A pair of landſcapes from Brecourt. "St John," from Manfredi, and a ſmall buſt of a man; the four former of which are engraved in lines, and the two latter in mezzotinto.

In the ſecond edition of his cabinet, are three other engravings by the marquis himſelf, *viz.* "A Magdalen," from J. F. Romanelli; "Portrait of the miſtreſs of Paolo Veroneſe," and "The Adoration of the Magi," from a compoſition of his own. The frontiſpiece of this ſecond edition, engraved by Coelmans, is alſo from a deſign by the marquis.

Antoine Aveline was born at Paris in the year 1662, and died in the ſame city in 1712. He engraved a great number of landſcapes, which are for the moſt part either compoſed, or drawn from nature, by himſelf, and are executed in a neat and agreeable ſtyle. Their ſubjects are principally as follow:

A ſeries of ſix landſcapes, marked Aveline inv. et fec. in 4to. Another ſeries of twelve landſcapes, not numbered, and marked in the ſame manner. Another ſeries of ſixteen views of Verſailles, in folio. Twelve views of chateaus and royal manſions, namely, Trianon, the Menagerie, two views of Clagny, Marly, St. Germain en Laye, Vincennes, St. Cloud, Meuden, Rambouillet, and Chantilli de Chambre, in folio. Twelve views of Paris and ſeveral of its edifices, namely, the city of Paris, the Invalids, two views of the Thuilleries, the Palais Royal, the Luxembourg, the Pont Neuf, Places des Victoires, Hotel de Ville, Notre Dame, the Obſervatory, and the Salpetrières, in folio. Series of twenty views of cities, namely, Lyons, Marſeilles, Havre de Grace, Rouen, Bourdeaux, Breſt, Straſburg, Baſle, London, Amſterdam, Rome, the church of St. Peter, Venice, the place de St. Mark, Turin, Liſbon, Conſtantinople, Jeruſalem, Tripoli, and Tangiers.

Gaſpar Duchange was born at Paris in the year 1662, and died there in 1759. Whether he ſtudied in the ſchool of Audran, or under any maſter, his biographers have not mentioned; but his ſtyle of engraving moſt reſembles that of John Audran, who was his contemporary, though a few years younger than himſelf. He deſervedly obtained the title of engraver to the king, and in the year 1707 was admitted a member of the Royal Academy of Arts. Strutt ſays of him, ſomewhat too coldly, that his ſtyle is neater than that of Audran, and the etching not ſo predominant, but that his drawing is leſs correct and his extremities not marked with ſo maſterly a hand, yet that his prints have much to recommend them to notice; more eſpecially to the notice of ſuch connoiſſeurs as are pleaſed with an agreeable management of the graver. Watelet, with more generous diſcernment, ſays of Duchange, that he was one of thoſe engravers who has beſt ſucceeded in combining mellowneſs with ſtrength in his plates, without imparting coldneſs. It may alſo be ſeen in his works that he repreſented moſt happily the delicate texture of fleſh in his female figures, and that no other of the French artiſts ever excelled him in this reſpect.

It ſeemed as if he had been eſpecially fitted by nature to engrave from the pictures of Correggio; he executed, after this painter, the three celebrated prints of Io, Leda, and Danaë; and, by the ſoftneſs and harmony of his ſtyle, perfectly transfuſed the ſpirit, and imparted to his prints the tone, of this great maſter.

Duchange continued his labours till he reached the advanced age of ninety. He engraved ſome prints of the gallery of the Luxembourg; and in that of the debarkment of the queen at Marſeilles, has ſcarcely been leſs ſucceſsful than in his engravings after Correggio, which is more particularly obſervable in the three ſirens or mermaids who are mooring the galley, and on whom Rubens has laviſhed the graces of his art.

The beſt performances of this artiſt are in folio, and their ſubjects, "Jupiter and Io," after Correggio, drawn at Rome by P. de Pietro, and engraven at Paris by G. Duchange 1705. "Jupiter deſcending in a Golden Shower to Danaë," and "Jupiter in the Form of a Swan careſſing Leda," after the ſame artiſts. The moſt valued impreſſions of theſe beautiful prints are thoſe which were taken before they were retouched by Sornique, who has added draperies to them. "Chriſt in the Sepulchre," after a painting of Paul Veroneſe, in the cabinet of Crozat. This is a bold and vigourous print, much ſuperior to the one formerly engraven by Auguſtino Carracci. "The Birth of Mary de Medicis." "The landing of the Queen at the Port of Marſeilles." "The Citizens of Lyons going to meet the Queen." "The Apotheoſis of Henry IV." all after Rubens. "Solon explaining his Laws to the Athenians," and its companion, "The emperor Trajan adminiſtering Juſtice to his Subjects," both after Noel Coypel. Two ſubjects after the four paintings of Coypel the father, preſerved in the Luxembourg, (Charles Dupuis has engraven the two other ſubjects.) "The Repaſt at the Houſe of Simon the Phariſee," after a painting of Jouvenet in the church of St. Martin in the Fields. "Jeſus expelling the Sellers of Merchandize from the Temple," from a picture of the ſame maſter, preſerved in the ſame church. "The Reſurrection of the Widow's Son," after the ſame, in the church of the Recollets at Verſailles. "Clytie abandoned by Phœbus," after Nic. Bertin, an oval. "Diana diſarming Cupid," after Deſormeaux, engraven in 1718.

The following are all after Antony Coypel: "The Sacrifice of Jephtha. "Tobias recovering his Sight through the Interpoſition of his Son," a capital engraving. "Mary Magdalen." "St. Cecilia," an upright. "The Death of Dido." "Juno borrowing the Ceſtus of Venus." "Venus aſleep." "Diana at the Bath." A ſet of four plates of "The Elements," engraven by Duchange and Des Places. "The Infant Jeſus in the Cradle," after Charles Coypel, engraved by Duchange, at the age of 87.

Duchange has likewiſe engraven ſeveral ſubjects from the paintings of Le Sueur in the hotel du Chatelet.

His beſt portraits are thoſe of Francis Girardon, painted by Rigaud. Charles de la Foſſe, painted by the ſame, and engraved for Duchange's reception into the Royal Academy. Antoine Coypel, ſeated at his eaſel, with his infant ſon Charles by his ſide, painted by himſelf, and engraven by Duchange in 1752.

Antoine Trouvain was born at Montdidier about 1666, and nominated a member of the academy of painting in 1707. He handled the graver with much dexterity, and executed his works in a very neat and agreeable ſtyle. It is not known in what ſchool he ſtudied, though it is probable he received leſſons from Bernard Picart, at leaſt he appears cloſely to have imitated the ſtyle of that artiſt.

He engraved with ſucceſs both portraits and hiſtorical ſubjects, of which the chief are of the folio claſs, and their ſubjects as follow:

"The Salutation of the Virgin," after Carlo Maratti. "Jeſus curing the Blind," after a painting of Ant. Coypel in the Chartreuſe. "The Nuptials of Queen Mary de Medicis with Henry IV." after Rubens. "The Minority of Louis XIII." after the ſame painter, which form part of the collection in the gallery of the Luxembourg. "A drunken Silenus ſurpriſed by two Shepherds," after Ant. Coypel.

Portraits

Portraits.—The holy Vincent de Paul II. Trouvain, ſc. (ſmall folio.) Father de la Chaiſe, confeſſor to Louis XIV. in 8vo. Pierre-Daniel Huet, biſhop of Avranches, after S. de Quoy, in 8vo. Alexis de Buc, prieſt of the congregation of Scribes, after P. Simon, engraven in 1689, in folio. Francis le Bouthillier, biſhop of Troyes, in folio. Claude-Francis Menetrier, of the ſociety of Jeſus, after P. Simon Jean Peſne, painter and engraver, painted by himſelf, engraven by Trouvain 1698. René Antoine Houaſſe, painter and rector of the academy, painted by Tortebat, engraven by Trouvain, for his reception into the academy in 1707, in folio, and Jean Jouvenet, painted by himſelf, engraven by Antoine Trouvain, for his reception into the academy; alſo in folio.

Pierre Drevet the elder was born at Lyons in the year 1664, and died at Paris in 1739. After receiving leſſons in drawing, and probably in engraving alſo, from Germain Audran in his natal city, he went to Paris for improvement, and as Strutt with great probability ſuppoſes, ſtudied for a time under Girard Edelink. He ſoon became a moſt admirable engraver of portraits, to which he chiefly confined his talents, and the encreaſe of his reputation was proportionably rapid. He now contributed to ſpread through Europe the likeneſſes of the royal and noble perſonages of the day; and the fame of Hyacinthe Rigaud the portrait painter, (the anceſtor of the preſent academician of the London Royal Academy,) went hand in hand with his own.

His command of the graver, which is believed to have been the ſole inſtrument of his art, was very great. His engraving is firm though delicate; and his plates highly finiſhed. He drew well, and had the rare art of transfuſing much of the ſtyle and feeling of the painter after whom he was working. In ſhort, the beauty of execution, ſoftneſs, and truth diſplayed in his portraits, have ſtamped on them a value which time ſhall yet be long in effacing.

The only hiſtorical ſubjects from his hand, with which we are acquainted, are "The Entrance of Jeſus Chriſt into Jeruſalem," from a grand compoſition of Ant. Drew, in folio, and "A Crucifixion," with the city of Jeruſalem in the back ground, a large folio, engraved on two plates, and inſcribed P. Drevet exc.

His portraits are numerous, and excepting that of André Felibien, after Le Brun, (which is in 4to.) are of the folio ſize. After N. de Largilliere he has engraven Jean Foreſt. Nicholas Lambert. Maria de Lambeſpine. Helena Lambert, after F. de Troy. Frederic Auguſtus king of Poland, and Nicholas Boileau Deſpreaux, (a ſmall folio.) After de Pelis, and after Vanderwerf, Oliver Cromwell, with attributes. But his principal performances, both in number and merit, are after H. Rigaud, and it is believed that few of theſe are omitted in the following liſt:

Mary de Serre, the mother of Rigaud. Hyacinthe Rigaud himſelf. Nicholas Boileau Deſpreaux. Chriſtina Caroline, margravine of Brandenbourg, &c. Erneſt Auguſtus duke of Brunſwick Lunenbourg, in an allegorical border. Alexander de Bourbon, Comte de Toulouſe, with a glove on the hand; another plate of the ſame ſubject, with the glove removed. Philip V. king of Spain. René-François de Bouveau, archbiſhop of Narbonne. André Hercule, cardinal de Fleury. Maria, ſovereign of Neufchatel, ducheſs of Nemours, engraven in 1707. Louis-Antoine, duke de Noailles. Louis Hector, duke of Villars, the moſt valued impreſſions of which are before the inſcription was altered. Louis, dauphin of France. Francis Louis de Bourbon, prince of Conti, a whole length. Louis XIV. in his royal robes, a whole length figure. Louis XV. ſeated on the throne, clad in his royal robes, companion to the former.

Pierre Devert, the younger, the ſon of the former, was born at Paris in the year 1697, and died in the ſame city in 1739, ſo that Europe loſt both theſe admirable artiſts in the courſe of the ſame year. The ſon had the advantage of the father's inſtruction in that art in which he was deſtined to ſhine ſo conſpicuouſly, and for which he manifeſted an early genius. At the age of thirteen he ſurpriſed the artiſts and amateurs of Paris with an engraving ſo well performed, that probably no man, his father excepted, could have ſurpaſſed it; at the age of nineteen he engraved his folio plate of the Reſurrection, and at the age of twenty-ſix he executed his celebrated whole length portrait of Boſſuet, which has ſince been the admiration of Europe.

Watelet obſerves of the ſenior Drevet, that he might have been regarded as the firſt portrait engraver in the world, in point of delicate and beautiful execution, had he not been exceeded in this reſpect by his ſon; but upon ſuch an occaſion, all idea of rivalry is abſorbed in the reſpect due to the filial and parental feelings. When a father transfers the fruits of his experience, and ſets before his ſon, as rudiments, the final reſults of his own ſtudies, nature ſteps in and identifies their fame.

His whole length portrait of Samuel Bernard is a ſtill more ſurpriſing effort of art; and in both theſe prints the varied expreſſion of the ſurfaces of natural objects;—of fleſh, hair, (particularly the white hair of Boſſuet,) ermine, lawn, lace, mohair, velvet, gold-fringes, carved wood, bronze, marble paper,—each engraven in a peculiar and appropriate manner, may well excite wonder, and moſt the wonder of thoſe moſt intimately converſant with the capabilities of the art. To all this variety of ſubſtances he has imparted the moſt exquiſite finiſh, yet no where is there any affected diſplay of dexterity in the uſe of the graver, as is too frequently obſervable in the works of other engravers, who do not poſſeſs half the powers of Drevet; on the contrary, a violet-like modeſty here adds the charm of innocence to the attractions of beauty.

Drevet did not, however, confine himſelf to portraits, but his abilities were perhaps leſs well adapted to the generaliſed energies of hiſtory, than to the details of portraiture; and it muſt be acknowledged, even of his "Preſentation of Chriſt in the Temple," which is eſteemed his maſterpiece, that its general complexion,—probably from being executed entirely with the graver and dry-needle,—is too metallic.

M. Cochin has obſerved of the engravings of Drevet the younger, "that they are admirable for delicacy and beauty of execution, but much too laboured for the character of hiſtory, which has led perſons of taſte to ſay that his fine engraving is extremely clever, but altogether miſplaced, and tends to impart to his figures the appearance of bronze;" and Huber remarks upon this critique, "that it is applicable only to thoſe prints which he engraved after Ant. Coypel." The truth however lies between theſe critics, who were each ſomewhat biaſſed on the occaſion, by his excluſive preference for a particular mode of art.

The principal hiſtorical works of the junior Drevet are of the folio claſs, and their ſubjects as follow:

"The Adoration of the Shepherds," after Hyacinthe Rigaud. "A Holy Family," which is inſcribed "le parfait modele de toutes les familles Chretiens," after Ant. Dieu. And from the ſame maſter, "John the Baptiſt reproaching

Herod for having eſpouſed his Brother's Wife;" and, "The Entrance of Jeſus Chriſt into Jeruſalem."

From the pictures of Ant. Coypel he has engraven, "The Eternal denouncing Adam and Eve after their Tranſgreſſion," with a copy of the ſame, of ſmaller dimenſions, engraven with the utmoſt delicacy. "Abraham about to ſacrifice his Son Iſaac," engraven in 1707. "The Servant of Abraham with Rebecca at the Well." "The Annunciation of the Virgin," with the ſame piece under the ſame title, of a ſmaller ſize. "A Chriſt on the Croſs." "Jeſus Chriſt in the Garden of Olives, comforted by Angels," after J. Reſtout. "The Preſentation of the infant Jeſus in the Temple," after a painting of L. de Boullongne in the choir of Notre Dame, at Paris, a large and capital piece. "The Reſurrection of our Lord," after J. André, engraven by P. Drevet at the age of nineteen.

His principal portraits are alſo in folio, and are thoſe of Francis de Salignac de la Mothe Fenelon, archbiſhop of Cambray, after Jean Vivien. Francis Paul de Neuville de Villeroy, archbiſhop of Lyons, after J. Santerre. Claude le Blanc, miniſter of war, after Ad. le Prieur. Louis, duke of Orleans, after Ch. Coypel. Adriana le Couvreur, in the part of Cornelia, after the ſame, a diſtinguiſhed piece. Louis XV. in his youth, conducted by Minerva to the temple of Glory, after Ant. Coypel. Dom Arnoul de Loo, ſuperior-general of the congregation of St. Maur, after Jouvenet. Nicolas-Pierre Camus de Pontcarré, firſt preſident of the parliament of Rouen, after the ſame. The Wife of the Pretender, Davids pinx. Romæ. Iſaac-Jacques de Vertamont, biſhop of Conferans, after Fr. de Troy. Robert Cotte, firſt intendant of buildings, gardens, arts, and manufactures of the king, &c. painted by Rigaud, and engraven by P. Drevet, jun. for the Academy. René Pucelle, abbé and counſellor of the parliament, after the ſame. Guillaume, cardinal Dubois, archbiſhop of Cambray, ſitting, engraven in 1724. Samuel Bernard, ſitting, after the ſame. The early impreſſions of this plate are known by having been taken before the words "Conſeiller d'Etat" were inſcribed beneath. Jacques-Benigne Boſſuet, biſhop of Meaux, a whole length figure, after the ſame, of which we have already ſpoken.

Claude Drevet, firſt couſin to the preceding, was born at Lyons in 1710, and died at Paris in 1768. Educated by Drevet, he diſtinguiſhed himſelf by engraving portraits, in which he imitated the ſtyle of his couſins with conſiderable ſucceſs. His principal works are in folio, and are the portraits of Madame le Bret, as Ceres. Henry Oſwald, cardinal d'Auvergne. Charles Gaſpar Guillaume de Vintimille, archbiſhop of Paris. Philippe Louis, count de Sinzendorf, all after H. Rigaud. Pierre Calvairac, doctor in theology, abbé of Pontignan, is after Adrien le Prieur.

Antoine Rivalz was born at Toulouſe in the year 1667, and died in the ſame city in 1735. He was the ſon of Jean-Pierre Rivalz, who was both architect and painter, and under whom, and the celebrated La Fage, our artiſt received the elementary part of his education. He afterwards proceeded to Paris, and from thence to Rome, in order to finiſh his ſtudies.

Rivalz was both painter and engraver, and during his ſtay at Rome painted the fall of the rebellious angels, for the prize given by the Academy of Luke, and being declared the ſucceſsful candidate, was crowned in the capitol by cardinal Albani, afterward pope Clement XI. He was recalled from Rome by his father, who died a ſhort time after his arrival at Toulouſe.

He poſſeſſed conſiderable talent at imitating the works of other artiſts, and even when he meant to be original, his own reſembled either the compoſitions of Pouſſin or thoſe of La Fage.

The following ſpirited etchings are by his hand, and from his own compoſitions: "Truth driving away the Vices, the Enemies to Art and Science," an allegory to the memory of Pouſſin, inſcribed to Le Brun. "The Martyrdom of St. Symphorianus," a middling-ſized plate, nearly ſquare; and four ſmall allegorical ſubjects, for a treatiſe on painting which Rivalz publiſhed at Toulouſe.

Bartholomew Rivalz was the nephew and pupil of Antoine, and etched the following ſubjects in ſmall folio, chiefly from the compoſitions of his uncle:

"The Fall of the rebellious Angels," the painting of which is at Narbonne. "Pætus and Arria;" "Cleopatra;" "Judith and Holofernes;" "Joſeph and the Wife of Potiphar;" "The Death of Mary Magdalen," after Benedetto Lutti, a ſmall upright.

Edme Jeaurat was born at Paris about 1672, and died in the ſame city in 1738. He was the pupil of B. Picart, and, like his maſter, poſſeſſed the happy talent of ſeizing the ſpirit of the great painters whoſe works he copied. Speaking of this engraver, Dandre Bardon obſerves, that he transfuſed all the fire of Du Mole into "The Flight into Egypt," which he engraved after this maſter; the pictureſque beauties of Paul Veroneſe into his "Finding of Moſes;" the ſpirit of Vleughel into his print of "Achilles plunged into the Waters of the Styx;" and the graces of Le Clerc into his print of "Achilles recognized by Ulyſſes in the Palace of Lycomedes."

Strutt has confounded this artiſt with Etienne Jeurat, the painter, an error which it is the more neceſſary to correct, ſince Etienne was a very inferior artiſt, incorrect in his deſign, cold in his execution, and whoſe knowledge did not extend beyond the mere mechaniſm of his art.

The principal works of Edme Jeaurat are the portraits of Nicolas Vleughel, a Pariſian painter, after Ant. Peſne, engraven in 1726. Pierre Pujet, painted by Pujet the ſon, both in folio. Eight fables of Fontaine, after Etienne Jeaurat.

After N. Vleughel he engraved "The Meeting of Abigail and David." "The Reſurrection of our Saviour," engraven in 1718. "Thetis plunging Achilles into the Waters of the Styx." "Telemachus in the Iſle of Calypſo," engraven in 1724, all of the folio claſs. A ſet of three plates of "A Roman Maiden," "A Virgin of Freſcati near Rome," and "A Greek Woman in a Pilgrimage to Rome," engraven in 1734, in quarto. "Jeſus Chriſt in the Temple diſputing among the Doctors," in quarto. "Achilles recognized by Ulyſſes in the midſt of the Daughters of Lycomedes," after Le Clerc. "Jupiter enamoured of a Nymph," after the ſame. "John the Baptiſt baptizing the Jews in the Waters of Jordan," after Pouſſin. "Syrinx, purſued by the God Pan, is received by the River Alpheus," after P. Mignard. "The Body of Jeſus on the Knees of the Virgin," after Le Brun. A ſet of three ſubjects, from Le Brun's deſigns for the Gobelin tapeſtries, repreſenting "The Reduction of the City of Marſal;" "The Interview in the Iſle of Pheaſants;" and "The Ceremony of the Marriage of Louis XIV." But the three following prints in the collection of Crozat are the moſt celebrated engravings of Jeaurat, and are all of the folio claſs, namely, "The Interview of Jacob and Rachel," after a painting of P. Fr. Mola. "Repoſe during the Flight into Egypt," after the ſame. "The finding of Moſes," after Paul Veroneſe.

Claude

Claude Gillot was born at Langres in 1673, and died at Paris in 1722. His father, who was a painter, communicated to young Claude all the knowledge of which he was maſter, and afterwards ſent him to Paris to proſecute his ſtudies in the ſchool of Jean Baptiſte Corneille.

Fauns, ſatyrs, and other comic and ſatirical ſubjects were the favourites of his pencil. On account, however, of ſome productions which he executed, of a more ſerious character, he was admitted into the Academy of Painting in 1715.

Gillot had the honour of giving leſſons to the celebrated Watteau; but they ſeparated after a ſhort time, as is ſaid, from the envy felt by the maſter at the ſuperior talents of his pupil. As Watteau roſe to eminence, Gillot gradually relinquiſhed painting, and dedicated his time to engraving. His pictures are now forgotten, but his drawings and etchings are ſtill ſought after by the curious.

The principal works of Claude Gillot are in ſmall folio, and their ſubjects as follow: "The Feſtival of Diana interrupted by Satyrs," Cl. Gillot fecit. "Feaſt of Bacchus celebrated by Satyrs and Bacchantes," id. fec. "Feſtival of Pan celebrated by Sylvans and Nymphs," id. fec. "Feſtival of the God Faunus," id. ſc. Theſe four are all of the ſame ſize, and form a ſet: the plates for the fables of La Motte Houdart are alſo by Gillot.

Nicholas Henry Tardieu was born at Paris A. D. 1674, and died in the ſame city in 1749. He ſtudied under Le Pautre and Jean Audran, was admitted a member of the French academy in the year 1720, and in the courſe of a long profeſſional career produced many excellent engravings, and educated many able pupils, among whom were Cars, B. Baron, Le Bas, and Tardieu the ſon.

Tardieu was a good draftſman, and brought his plates very forward in the etching, finiſhing them afterwards with the graver in a manner that ſhews the ſoundneſs of his taſte; few before him had mingled, with ſo much addreſs, free hatchings with regular courſes of lines. There is much depth of tone in his prints, and in general a vigorous and tolerably well harmonized chiaro-ſcuro. He was engaged in the execution of ſome of the moſt celebrated works of his time, ſuch as the collections of Crozat and of Verſailles, and the pictures of Le Brun.

Of his numerous hiſtorical engravings, which are in general of the folio dimenſions, the following will be found the moſt remarkable:

A pair of grand friezes, the one repreſenting the family of Coriolanus kneeling before him; the other, the taking of Carthage by Scipio, after Julio Romano. Another pair of large friezes, after the ſame maſter, one repreſenting the continence of Scipio; the other Scipio rewarding his ſoldiers. "Jupiter enamoured of Alcmena," after the ſame painter. "The Annunciation," after Carlo Maratti. "A Holy Family," in which the Virgin is ſeen ſeated, holding the infant Jeſus, to whom angels preſent fruits and flowers, after André Luigi d'Aſſiſe. "Adam and Eve after the Fall," from a painting of Dominichino, in the poſſeſſion of the duke of Devonſhire; one of the moſt beautiful prints of Tardieu, and engraven with much more preciſion than the ſame ſubject by Baudet. "The Scourging of Chriſt," after Le Brun, in folio. "Chriſt on the Croſs, at the Foot of which are ſeen Mary Magdalen, St. John, and the Virgin," after the ſame. "The Body of Chriſt," a compoſition containing three figures, after the ſame. "Holland," painted alſo by le Brun in the war ſaloon at Verſailles. "Wiſdom, Secrecy, Valour, and Prudence," the four chief qualities of a perfect miniſter, after Le Sueur, a rare print. "Jeſus ſpeaking to the Samaritan Woman," after Nic. Bertin. "Jeſus appearing to Mary Magdalen as a Gardener," or the "Noli me tangere," after the ſame. "The Martyrdom of St. Peter," after Seb. Bourdon. "A Crucifixion," after Joſeph Parrocel. "St. Charles Boromeus," after P. Dulin. "The Salutation of the Virgin," after a painting in the dome of the Aſſumption, by Ant. Coypel.

From the ſame maſter Tardieu has engraven "Vulcan ſhewing Venus the Arms prepared for Æneas." "Venus in the Aſſembly of the Gods, ſoliciting Jupiter in favour of Æneas." "Juno ſoliciting Æolus to raiſe a Tempeſt againſt the Fleet of Æneas;" which three prints make part of a ſeries engraven after the paintings of the hiſtory of Æneas in the Palais Royal. "Apollo and Daphne." A pair of capital engravings of "The Conteſt between Agamemnon and Achilles;" and "The Parting of Hector and Andromache," and another pair from the ſtory of Cupid and Pſyche.

From the pictures of Watteau he has engraven "The embarraſſing Propoſal;" "Paſtoral Pleaſure;" "The Elyſian Fields;" "The grand Embarkation for Cythera;" and from the pictures of Rubens, twelve plates of the Hiſtory of Conſtantine the Great.

Elizabeth-Claire Tournay, wife of N. H. Tardieu, alſo diſtinguiſhed herſelf by engraving the following ſubjects:

"The Concert," after J. F. de Troy. "The Muſtard Merchant," after Ch. Hutin. A pair of "The Charitable Lady," and the "Catechiſing Prieſt," after P. Dumeſnil, the ſon. "An Old Coquette," after the ſame, and "Tranquil Sleep," after Et. Jeaurat, all in folio.

Jaques-Nicholas Tardieu, the ſon, was born at Paris in 1718, and was alive in 1789. Being educated by his father, he aſſiſted in the execution of ſeveral large works. In general young Tardieu employed the graver much more than the point. Hence his prints are more ſolid than thoſe of his father, but leſs rich in thoſe rougher energies which charm the eye of the connoiſſeur. He was a member of the Royal Academy, and occaſionally occupied himſelf both with engraving portraits and hiſtorical ſubjects.

His wife, Louiſa du Vivier, who was the daughter of the celebrated medaller of that name, and is well known for ſeveral reſpectable engravings.

The following is a liſt of a few of the beſt works of J. N. Tardieu:

"Jeſus Chriſt appearing to the Virgin," after Guido. "A Magdalen in the Deſart," after Paul Pagani. "Our Saviour curing the Paralytic," after Reſtout. "Diana and Acteon," after Fr. Boucher. "Monument to the Memory of Andeſley Schovel," after the ſame. "The Flemiſh Breakfaſt," and "The Alchemiſt," two companion prints, after D. Teniers. "The Miſeries of War," after the ſame. Two landſcapes, entitled "The Sweeper," and "The Fruits of Autumn," after Cochin the ſon, all of the folio claſs.

He has likewiſe engraven, conjointly with his father, ſeveral frontiſpieces and vignettes after Cochin, as well as ſeveral ſubjects for the collection of the gallery of Verſailles, from the drawings of Maſſe, after Le Brun.

His beſt portraits are in folio, and are thoſe of Robert Le Lorrain, ſculptor in ordinary to the king, painted by Nonotte, and engraven by Jac. Nic. Tardieu, for his reception in the academy in 1749. Bon de Boullongne, painter in ordinary to the king, painted by Gilles Allon, engraven by the ſame Tardieu, for his reception at the academy in 1749. A whole length figure of Louis XV., after Vanloo. The queen of Louis XV., after Nattier. Maria Henrietta of France, after the ſame. Dimetri, prince Gallitzin, ambaſſador extraordinary from the court of Ruſſia to that of Vienna, after Drouais the ſon. The archbiſhop of Bourdeaux, after Reſtout.

Pierre-

Pierre-François Tardieu, couſin-german of the former, was born at Paris about 1720. He was taught the art of engraving in the houſe of Tardieu, whoſe manner he cloſely copied. The moſt conſiderable works of this artiſt are the following:

"The Judgment of Paris," after Rubens, in folio. "Perſeus and Andromeda," after the ſame, in folio. Different pieces of architecture, after Panini. Several plates for the large edition of Fontaine's Fables, after Oudry. Several plates of animals for Buffon's Natural Hiſtory.

Marie-Anne Rouſſelet, the wife of P. F. Tardieu, alſo engraved ſeveral ſubjects, and among others, "St. John in the Deſart," after Claude Vanloo, in folio; and ſome of the plates for Buffon's Natural Hiſtory.

Claude Duflos was born at Paris A. D. 1678, and died in the ſame city in 1747. Under what maſter he ſtudied has not been mentioned: his ſtyle appears to be formed from ſtudying the beſt works of Edelink and De Poilly, and though he occaſionally called in the aid of etching and the dry point, he worked chiefly with the graver, handling that inſtrument with great dexterity, yet with a dexterity perfectly ſubſervient to his knowledge of drawing, in which he was no mean proficient. His engravings are finiſhed with conſiderable care and neatneſs, but in their general complexion are ſomewhat cold and metallic when compared with thoſe of Audran and Duchange.

From the numerous catalogue of his hiſtorical works we ſelect the following, which are all of the folio dimenſions:

"The Victory of St. Michael over the Devil," an upright, engraved for the Crozat collection; and "The entombing of Chriſt," both after Raphael. The ſame ſubject. "The entombing of Chriſt," after Pietro Perugino, for the Crozat collection. "Jeſus Chriſt with his Diſciples at Emmaus," after Titian, from the ſame picture, which was engraven by Maſſon. The ſame ſubject, after Paul Veroneſe. "A Concert of Muſic," after Dominichino, and "A Buſt of the Virgin," after Guido.

From the pictures of Albano he has engraven "The Annunciation." "Jeſus Chriſt as a Gardener, appearing to Mary Magdalen," or the "Noli me Tangere." "St. Cecilia," and "Love deſpiſing Riches." "The Preſentation of our Saviour in the Temple," after a painting of Le Sueur, in the grand ſeminary of St. Sulpice. "The Deſcent from the Croſs," after a painting by the ſame artiſt, in the church of St. Gervais, an oval. "The Woman taken in Adultery," after Nic. Colombel. "The Repaſt at the Houſe of the Phariſee," after the ſame. A companion to the former is engraven by M. Doſſien. "Monk Zozimus adminiſtering the Holy Sacrament to St. Mary the Egyptian," after Lubin Baugin.

The following eight are from the pictures of Le Brun; "The Maſſacre of the Innocents." "Jeſus Chriſt on the Mount of Olives." A large crucifix, with the inſcription "Helas! eſt ce amour," &c. "A Crucifix with Angels," copied from the beautiful print of Edelink. "The Body of Chriſt at the Foot of the Croſs, with the Three Maries and St. John." "Deſcent of the Holy Spirit on the Apoſtles." "The Aſſumption of the Virgin." "The repentant Magdalen," (with four French verſes).

The following ſix are from Ant. Coypel, *viz.* "The Annunciation." "Mary Magdalen at the Foot of the Croſs." "The Triumph of Galatea." "Love ſtung by a Bee," an oval, with "Zephyrus and Flora," for a companion print, and "the Marriage of Bacchus and Ariadne." A pair of upright plates of "The Triumph of Amphitrite," and "The Triumph of Bacchus," after Charles Natoire, cloſes our liſt of the hiſtorical works of Claude Duflos.

His beſt portraits are thoſe of Jean François Paul de Gondy, cardinal de Retz, in 4to.; and in folio, Nicolas Lyon, procureur to the king, after L. Herluyſon. Denis François Bouthillier de Chavigny, biſhop of Troyes, after H. Rigaud. Jean Jacques Gaudart, counſellor to the king, after De Largilliere. Phillippe, duke of Orleans, after R. Tourniere, and Marc Renée de Voyer, after H. Rigaud.

François Chereau was born at Blois in the year 1680, and died at Paris in 1729. He viſited Paris when very young, and ſtudied in the ſchool of the Audrans; though his ſtyle of engraving rather reſembles that of the Drevets.

Chereau is diſtinguiſhed by the correctneſs of his outline, and the beauty of his execution. He appears to have worked entirely with the graver, which he handled with great care and ability, but which, when not mingled with the more pictureſque reſults of etching, is apt to produce a cold and laboured appearance, ſuch as is but too evident in the otherwiſe meritorious engravings of this artiſt. He has alſo impaired the brilliancy of his chiaro-ſcuro, by working his lights to too low a tone. The following, which are of the folio ſize, will probably be found among the beſt of his hiſtorical works:

"St. John in the Deſart," after Raphael, a ſmall upright, engraved for the Crozat collection. "The Crucifixion," (a large upright) from Guido. "St. Catherine of Sienna," after Frere Jean André. "St. Celicia chanting the Praiſes of the Almighty," after P. Mignard. "St. Thereſa in Contemplation," and "St. Ignatius," founder of the ſociety of Jeſuits.

The following five portraits are inſcribed with his own name, as the painter or deſigner, as well as the engraver. Raoux, biſhop of Montpellier, in folio. Charles Hyacinthe Dangot du Bouillon, procureur general, in folio, an oval. Jacques Saurin, a celebrated preacher of the reformed religion, in 4to. and alſo an oval. Pierre Bayle, the celebrated critic, in 4to. Chriſtine Renate Zorn, engraven in 1716, in 4to.

After other maſters, he has engraven, of the folio ſize, Louis de Boullongne, painted by himſelf, engraven by Fr. Chereau for his reception into the academy in 1718. Nicolas de Largilliere, painted by himſelf. Charles Nicolas Taffourréau de Fontaine, biſhop of Embrun, painted by Rigaud the younger. The ſix following are after the pictures of the elder Rigaud. Jean Baptiſte Louis Picon, counſellor to the king. Nicolas de Launay, director of the mint. Claude Bernard Rouſſeau, counſellor to the king. Conrad Detlew de Dehn, miniſter to the duke of Brunſwick Lunenbourg. Andre-Hercule, cardinal de Fleury, prime miniſter. Melchior, cardinal de Polignac; in folio, a capital portrait. Louis Pecour, ballet maſter, painted by Rob. Tournieres, another capital portrait. Elizabeth Sophia Cheron, wife of Jacques le Haye, painted by herſelf. Euſebe Renaudot, an abbé, and diſtinguiſhed ſcholar of the laſt century, after Ranc; and Louiſa Maria, princeſs of Great Britain, after A. S. Belle, an oval.

Jacques Chereau (called the younger) was born at Blois in the year 1694, and died at Paris in 1759. He became the pupil of his elder brother François, but poſſeſſing no original powers, he could only imitate, which however he did with ſome ſucceſs. Invited hither by Du Boſc, he viſited England, but found, or fancied, that his talents were undervalued, and returned to Paris.

He appears, however, not to have been more ſucceſsful as an artiſt in his native country, for we find that he ſoon afterward

afterward relinquiſhed engraving altogether, and confined his attention to the traffic of a print-ſhop, which had devolved to him by the death of his brother.

We begin our account of the hiſtorical prints of Jacques with thoſe which he engraved after the pictures of Raphael.

"St. John in the Deſart, diſplaying a Burning Croſs." "The Virgin ſeated in a Landſcape, holding the infant Jeſus, and the little St. John kneeling by her Side," for the Crozat collection. This piece, which is known under the name of "La Belle Jardiniere," was likewiſe engraven by Rouſſelet. "The Transfiguration," a large upright, arched at the top. "A Holy Family," in which the Virgin is ſeen with the infant Jeſus on her knees, who is regarding St. Joſeph. Theſe, as well as the remainder of his hiſtorical works, are all of folio dimenſions. "David bearing the Head and Sword of Goliah," after a painting of Dom Feti. "David, from the Top of his Houſe, viewing Bathſheba," after Raoux. "Jeſus waſhing the Feet of his Apoſtles," after Nicolas Bertin. "Iphigenia in Tauride," with the inſcription, "Quantum religio potuit, &c." after the ſame. "Vertumnus and Pomona," after François Marot. "St. Anne," after M. Corneille. "The Deſcent from the Croſs," after Charpentier. "Deſign for a Sarcophagus," after N. N. Coypel. "A Young Female careſſing a Dove," after Carlo Vanloo.

The following are the only portraits inſcribed with the name of J. Chereau as the painter or draftsman. Phillip of Orleans, regent of France, in 8vo. Profile of George I. king of England, engraven at London, in 4to, rare. Jean Marie Vicenti, chancellor of Venice, in 4to., round. Michael de Montagne, engraven in 1715, in 4to. oval. Jacques Auguſte de Thou, in 4to., oval. Jean Baptiſte Joſeph Languet d'Orgy, curé of St. Sulpice.

Portraits after different painters. Jean Soanen, biſhop of Senez, after Raoux, in folio. Charles Joachim Colbert, biſhop of Montpellier, after the ſame in folio; and Jane of Arragon, queen of Sicily, after Raphael in folio.

Louis des Plaus was born at Paris A. D. 1682, and died in the ſame city in the year 1739 or 1740. He ſucceſsfully mingled etching with the work of the graver, and the merit of his beſt works is ſo conſiderable, that Watelet ſcarcely allows him to be inferior to Audran; he was engaged, with the moſt eminent artiſts of his time, in engraving for the Crozat collection. His moſt eſteemed prints are in folio, and their ſubjects as follow: "Danaë receiving the Golden Shower," after Titian. A pair of uprights, after Paul Veroneſe, entitled "Wiſdom the Companion of Hercules," and "Paul Veroneſe between Vice and Virtue." From the ſame painter, he has alſo engraven "Happy Love," and a ſquare plate, entitled "Reſpect." "The waſhing of Feet," after a painting of Mutien in the metropolitan church of Rheims, a grand compoſition. "St. Claire borne on Clouds and ſurrounded by Angels, with the Dragon overthrown at her Feet," from a painting of J. B. Gauli, ſtyled the Bachiche. "The Adoration of the Kings," in which is ſeen on the one ſide St. Longin in his armour, and on the other St. John the evangeliſt with the chalice, after Jul. Romano. "The Triumph of Titus and Veſpaſian," after the ſame, a ſuperb print. "Calvary, or Chriſt between the Thieves," after Caracci, an upright for the Crozat collection. "The Martyrdom of St. Peter," after Calabreſe. "The Purification of the Virgin," after Tintoret. "Diana and Acteon," after Carlo Maratti. "The Rape of Helen," after Guido. "The Birth of Adonis," after Carlo Cignani. "Roman Charity." "Hercules combating the Centaurs." "The Sacrifice of Abraham." "The gathering of Manna," its companion. "The Sacrifice of the Prophet Elias;" and "The Splendour of the neighbouring Powers of France," are all after Ch. le Brun. Among his very beſt engravings may be reckoned the following, after Jouvenet. "Jeſus healing the Sick," a very large plate. "Elevation of the Croſs," and "The Deſcent from the Croſs," a pair of large uprights. "St. Bruno at Prayer." "Aſtyanax torn from the Arms of Andromache." "Venus cauſing Arms to be forged for Æneas."

After the pictures of Ant. Coypel, Des Places has engraven, "Triumph of Venus on the Waters." "Love diſarmed by a fair Nymph," an oval. "Love ſheltered in the Houſe of Anacreon." "Minerva drawing Truth from a Well, and expelling Error and Ignorance," engraven in 1716. "Alcides reſtoring Alceſtes to king Admetus." "Æneas ſaving his Family from the Conflagration of Troy." "Funeral Pomp of Prince Pallas," and "Jupiter tonans." The three latter connect with the ſeries painted from the hiſtory of Æneas, in the Palais Royal, and publiſhed in twelve large plates, engraven by the moſt celebrated engravers of the time.

From the pictures of Ch. Coypel, ſon of Antoine, we find a pair entitled "Sweet and pleaſing Education," and "Dry and repulſive Education," and "The Matron of Epheſus." And from thoſe of Louis de Boulogne "Fire" and "Water," two prints of the ſet of four elements, of which Charles Dupuis engraved "Earth" and "Air;" and "The Annunciation of the Virgin," after a painting in the chapel of Verſailles. "The Servant of Abraham delivering to Rebecca the Preſents ſent by his Maſter," after A. Guy Halle. "Diana and Endymion," after Nic. Fouché. "A young Girl, with a Bird," after Deſormeaux; and "A young Girl playing on a Lute," with the title "Amuſement eſpagnol," after Gil. Allou, are in 4to. "Abraham receiving Hagar," after Carlo Vanloo, "Venus bringing the Dictamnum to cure the Wound of Æneas," after J. B. Nattier. "Leda careſſed by Jupiter in the Form of a Swan," after P. Jac. Cazes. "Repoſe of Galatea," after the ſame. Of a ſet of four prints, called "The Surpriſes of Love," after the ſame painter, Des Places engraved two, namely "Achilles and Deidamia," and "Hercules and Omphale." The four ſeaſons, after the ſame, are engraven by him in conjunction with Beauvais. Two ſubjects after Watteau, "Painting," and "Sculpture." "Rural Repaſt." "The hunting of Lions and Tigers," after Ch. Parocel. "Orpheus obtaining from Pluto the Return of Eurydice," after Rubens.

The beſt portraits of our artiſt are thoſe of Everard Titon du Tillet, inventor of the French Parnaſſus, after N. de Largilliere. Marie Anne Duclos, a celebrated tragic actreſs, in the character of Ariadne, after the ſame. Charles François Silveſtre, youngeſt ſon of Iſrael, after I. Herault; and Pope Pius V. obtaining from heaven the victory of Lepanto, after Fre Jean André, engraven in 1714: and the three following are engraved from ſculpture, namely, "Antique Statue of Hercules killing the Hydra." "Marcus Curtius leaping into the Flaming Gulph," from the equeſtrian ſtatue by Bernini, in the gardens of Verſailles; and a ſtatue of "Leda," after Corneille van Cleve.

Charles Dupuis was born at Paris in 1685, and died in the ſame city in 1742. He was the pupil of Gaſpar Duchange, and afterwards became his ſon-in-law. He viſited England, but the climate not agreeing with his health, he returned to his native country, and was afterwards admitted a member of the Royal Academy.

In moſt of his prints, he employed the aid of aquafortis; he drew with conſiderable ability, and his works in general indicate, that he poſſeſſed a profound knowledge of his art. He engraved with equal ſucceſs portraits and hiſtory. The following are among the moſt eſteemed of his engravings, and are all of the folio claſs.

"St. John preaching in the Deſart," after Carlo Maratti, engraved for the Crozat cabinet. "Ptolemy Philadelphus granting Liberty to the Jews," after Ant. Coypel. "Alexander Severus cauſing Corn to be diſtributed to the Romans," after the ſame, both uprights. The four other ſubjects, which, with the two preceding form a ſet, were engraven by Duchange. Two prints, repreſenting "Air," and "Earth," after L. de Boullogne, in folio. The two others, "Fire," and "Water," (which complete the ſet of four elements) were engraven by Deſplaces. "Cupid triumphing over Pan," after Ant. Coypel. "Diana repoſing, ſurrounded by her Nymphs;" and "Rinaldo and Armida," after the ſame. "The Paſſage of the Rhine," after Le Brun. "The Marriage of Joſeph and Mary," after Carlo Vanloo. "King Charles I. repreſented in Priſon," after Raoux.

Charles Dupuis alſo engraved, after the paintings of Euſtache Le Sueur, in the hotel du Chatelet, from drawings by B. Picart, conjointly with Duchange, Duflos, Deſplaces, and Beauvais, "The Occupations of the preſent Age," after Ant. Watteau. "The Leſſon of Love," after the ſame, and "The philoſophic Huſband," Act V. ſcene laſt, after Nic. Lancret.

His moſt eſteemed portraits are thoſe of Jean Pittard, ſurgeon to king St. Louis. Ch. Dupuis del. et ſc. in 8vo. Henri de Lorraine, duke of Guiſe, termed the Gaſh, after Dumouſtier. Jerome Bignon, librarian to the king, after Coyzevox. Louis Marchand, organiſt to the king, after Robert, all in 8vo. but the following are of the folio ſize; Nicholas Couſtou, ſculptor to the king, painted by Le Gros, and engraven by Dupuis for his reception into the academy in 1730. Nicolas de Largilliere, painter to the king, painted by Gueulain, and engraven by Dupuis for his reception into the academy in 1730. Louis XV. ſitting, after Ranc, and Madame Bouché of Paris, in the coſtume of a veſtal, after Raoux.

Nicolas Gabriel Dupuis, the brother of Charles, was born at Paris about the year 1696, and died in the ſame city in 1770. He was at firſt a dyer, and was a long time occupied in engraving ornamental plates for printing linen. He was ſo extremely modeſt, that he never even dreamt of becoming a member of the academy; but having taken leſſons in engraving from Duchange, and executed ſome plates for the gallery of Verſailles, after Le Brun, from deſigns by Maſſe, he at length became better known, and his own merit, ſeconded by the intereſt of Le Brun, introduced him to the Royal Academy of France.

His merits were little inferior to thoſe of his elder brother; and his ſtyle, in the earlier part of his career, was the ſame; but diſcovering that the ſteams of aquafortis impaired his health, he ever after worked with the graver alone, handling that inſtrument with much freedom and facility.

Like his brother, he engraved both portraits and hiſtorical ſubjects; of which the following are the moſt celebrated:

"The Guardian Angel," after Dom Feti. "Amuſement of paſtoral Life," after Georgione, for the Crozat collection. "The Adoration of the Kings," after Paul Veroneſe, alſo for the Crozat collection. "The Death of Lucretia," after Guido. "St. Sebaſtian," after L. Carracci, engraven in 1770. "The Virgin and the infant Jeſus," after Annibal Caracci. "Æneas reſcuing his Father Anchiſes from the burning of Troy," after Carlo Vanloo. "St. Nicolas, (the patron of mariners,) and St. Francis at Prayer," after Pierre. "A ſleeping Nymph diſcovered by the Fauns," after L. Cheron. All theſe ſubjects are in folio.

Portraits.—Gaſpar Duchange, engraver to the king, painted by Vanloo the ſon, in 4to. Girard Audran, engraver to the king, from a model by Coyzevox. Charles Francis Paul le Normand de Tournehem, director general of the arts, painted by L. Toque, engraven by Dupuis for his reception into the academy in 1754. in folio. Phillip Wouvermans, a Dutch painter, after C. de Viſſcher in folio. Pedeſtrian ſtatue of Louis XV. erected in the city of Rennes, executed by Le Moine, in folio. Equeſtrian ſtatue of Louis XV. erected in the city of Bourdeaux, executed by the ſame, in folio.

Jean Du Vivier, or De Vivier, an engraver chiefly of dies for coins and medals, was born at Liege in 1687, and died at Paris in 1761. He came to Paris, and was admitted a member of the Royal Academy in 1718. He alſo received a penſion from Louis XV. and apartments in the gallery of the Louvre. Among all the artiſts of his time, Vivier ſeized the moſt ſtriking reſemblance of that prince. The moſt remarkable of the great number of medallions engraved by this artiſt are thoſe of the coronation of Louis XV., the equeſtrian ſtatue of this Prince, erected in the Place de Bourdeaux, the buſts of the king at different ages, and that of Peter the Great.

Delicacy and ſpirit characterized all the productions of Vivier; gentleneſs and modeſty were the prominent features of his moral character. He engraved with the ſame ſpirit on copper. His prints are all either inſcribed, Giovan, or G. de Vivier fecit.

The following, among other productions of this artiſt, are very much valued by connoiſſeurs:

The portraits of Bartholet Flamaël, a painter of Liege; and Pierre de Gouges, advocate of the parliament, after R. Tourniere, both in folio. "A Flemiſh Cook drawing a Fowl, and a Woman bringing her ſome Drink," inſcribed Ant. Van Heuvel pinx. G. de Vivier fec. aq. fort. 4to. "The entombing of Chriſt;" in the middle is an angel ready to cover the body with linen, on the right Joſeph of Arimathea holding a torch; inſcribed Anton. Van Heuvel inv. G. de Vivier fecit, in folio. "The Temptation of St. Anthony." In this print the venerable ſaint is ſeen kneeling before his praying deſk, rejecting the ſolicitations of a maquerelle with the wings of a bat, who is pointing to a courteſan richly attired. This is a very rare and curious work.

Nicolas Dauphin de Beauvais was born at Paris in 1687, and died in the ſame city in 1763.

Beauvais was the pupil of Jean Audran, and the ſon-in-law of Gaſpar Duchange.

From the circumſtance of his having engraved one of the ſeries of pictures which ſir James Thornhill painted for the cathedral church of St. Paul, the French writers on art have conjectured that he muſt have reſided for a time in London; but as no man may engrave plates within an Engliſh cathedral, a reduced copy was probably made from the original picture, and this might have been tranſmitted to Paris, with nearly the ſame eaſe, as to an artiſt's chambers in London.

The ſtyle of Beauvais varied at different periods of his life, and in his beſt works bears conſiderable reſemblance to

that of Edelink. Huber ſays that he poſſeſſed greater talents than he enjoyed reputation.

The works of this artiſt which are beſt known, are the following: The Virgin and the infant Jeſus on a Pedeſtal, beneath which are ſeveral Saints, after a celebrated painting by Corregio in the Dreſden gallery, known under the name of "St. George," a large upright. "The penitent St. Jerome," after Vandyke, the original of which is alſo in the Dreſden gallery. "The penitent Magdalen in the Deſart;" after B. Luti, for the Crozat collection. "The Triumph of Bacchus and Ariadne," after Pouſſin. "Cupid ſtealing Thunder from Jupiter," after le Sueur, a circle. "The burning and Metamorphoſis of the Veſſels of Æneas," and "The Death of Pallas," both after Coypel. "The Reſurrection of Chriſt," after P. Jac. Cazes. A ſet of, "The four Seaſons," after the ſame painter, engraven by Beauvais and Deſplaces. "The Pentecoſt, or Deſcent of the Holy Spirit," after Frere Jean André. "Elymas the Sorcerer ſtruck blind," after ſir James Thornhill. "And a Monument in honour of William Earl Cowper," all of the folio claſs.

Charles Nicholas Beauvais, the ſon, was born at Paris in the year 1730, and generally engraved in concert with his father. The only engravings which are known to have been executed by him alone, are the portrait of Juſte Aurele Meiſſonnier, (an architect,) from a drawing by himſelf, and a print after F. Boucher, entitled "Sleep interrupted."

For the family of Le Sueur, who were celebrated engravers on wood, and lived, ſome of them, about this time, ſee WOOD *Engraving*.

Frederic Hortemels was born at Paris ſome time about the year 1688. He always reſided in his native city, and appears to have ſtudied in the ſchool of Audran. Some few of his engravings have very little etching in them, but in his beſt prints he has more equally united the uſe of the point with that of the graver. They reſemble, in ſtyle, the engravings of Benoit Audran, but are ſomewhat more mellow, and many of them poſſeſs conſiderable merit: he has however been cenſured by ſome critics for the too abundant introduction of coarſe dots in his fleſh.

Of his plates, which were principally executed for the Crozat collection, the following will probably be found moſt deſerving the attention of the collector:

The portrait of Philip of Orleans, after J. B. Santerre. "Chriſt bearing his Croſs," after Georgione, and "The Adoration of the Kings," after P. Veroneſe, both engraved for the Crozat collection. "The Marriage of St. Catherine," after the ſame painter. "The Birth of St. John the Baptiſt," after Tintoret. "Chriſt and the Woman of Samaria," after B. Garofalo, engraved for the Crozat collection. "Cain contemplating his murdered Brother," after Andrea Sacchi, engraved for the ſame collection; and "The Pentecoſt, or Holy Ghoſt deſcending on the Apoſtles," after Gaudentio Ferrari, all of the folio claſs, but not very large.

Maria Madeleine Hortemels was born at Paris in the year 1690 or thereabout; according to Watelet ſhe was the daughter of Frederic Hortemels; but if the French writers have given in truly the dates of their reſpective births, this is impoſſible. It is more likely that Baſan is in the right when he calls her the couſin of Frederic; ſhe became the wife of Charles Nicholas Cochin the elder, and author of the following engravings, which are chiefly etchings performed with freedom and ſpirit, and finiſhed with the graver.

"Mercury announcing Peace to the Muſes," engraved (in a circle) from M. Corneille's cieling of the queen's ſaloon at Verſailles: "Penelope ſurrounded by her female attendants," and "Aſpaſia diſputing among the Grecian Philoſophers," are alſo after Michael Corneille.

After N. Bertin ſhe has engraven "St. Philip baptizing the Eunuch of Queen Candace;" and "Iphigenia," with the inſcription "Quantum religio potuit." "The Triumph of Flora" is after Pouſſin; and "Franche-Comté," conquered the ſecond time, after Le Brun. "Don Quixotte with a Beard," deſigned by Cochin junior, and engraven by his mother. "The charming Catin," after the ſame, engraven by the ſame. "The Singer of Canticles," after the ſame, engraven by the ſame. The above are all of the folio claſs. "The grand Lama and the king of Tangut," for a collection of voyages, by the ſame artiſts, in 4to. and the following folio portraits after Hyacinthe Rigaud, namely, Henry de Thiard de Biſſy, cardinal biſhop of Meaux, and Gaſton de Rohan de Soubiſe, cardinal biſhop of Straſbourg.

Charles Nicholas Cochin, the father, was born at Paris in the year 1688, and died in the ſame city in 1754. He was not the firſt of this name known as an engraver, being deſcended from Nicholas Cochin of Troyes, who flouriſhed about the middle of the ſeventeenth century.

The ſubject of our preſent notice cultivated painting till he attained the age of twenty-two years, and afterward devoted himſelf chiefly to engraving. He was an excellent deſigner, and engraved with much taſte and ſpirit, eſpecially when the figures were of the middle ſize. He was not equally ſucceſsful in thoſe of larger dimenſions, not being able, or not willing, to invigorate accordingly his ſtyle of execution. In his ſmaller works, his ſhadows are hatched with a looſe and free hand, and his forms drawn with much of artiſt-like feeling. Cochin publiſhed a great number of prints, of which we ſhall only mention the moſt celebrated.

The two portraits which he engraved for his reception into the Royal Academy in 1731, are thoſe of Jacques Sarazin the elder, ſculptor in ordinary to the king, and Euſtache le Sueur, painter in ordinary to the king, both in folio. "Alexander and Roxana," after Raphael, in folio. The ſame ſubject of the ſame ſize, but differently treated, the figures being without drapery; both of theſe engravings are in the Crozat collection. "Hercule Gaulois, or Eloquence," and "Calumny, painted by Apelles," after drawings by Raphael. It would appear that this pair of engravings on copper were combined with wood-engravings by Nicholas le Sueur, and printed in chiaro-ſcuro. "The Inflexibility of St. Baſil before Moteſt, Prefect of the Eaſt," after Fr. le Moine. "Jacob diſcovering himſelf to Rachael on his Arrival in Meſopotamia," after the ſame. "Jacob before Laban excuſing himſelf for his Artifice," after J. Reſtout; a companion print to the preceding. "The Deſtruction of Armida's Palace," after the ſame. "Jacob purſued by Laban," after N. Bertin. "The Servant of Abraham accoſting Rebecca," after the ſame. "The Trinity," and "The Aſſumption," from two paintings by Noel Coypel. "The Hiſtory of St. Auguſtin," engraven in ſeven plates, after L. Boullongne. The above are all of the folio claſs, but generally ſmall. The four following are in 4to. "Reception of a Biſhop under a Tent," after the ſame. Frontiſpiece for the order of St. Michael, after the ſame. "The Lame cured," after P. Jac. Cazes. A ſeries of fifty-two ſubjects of the hiſtory of Languedoc, after the ſame. "The Generoſity of Harmonia, Daughter of Gelon, King of Syracuſe," with an hiſtorical explanation, after J. B. M. Pierre. "A Converſation Piece in a Garden," after the ſame painter, in ſmall folio. The following are all after Watteau, and in folio. Two plates of "Italian Comedians

on the Stage." Another pair of "Love in the French Theatre," and "Love in the Italian Theatre." "The flying Camp," and "Return from the Campaign." "A Detachment of Soldiers making a Halt." "The Grove of Bacchus," and "The Village Bride," a capital piece both of the painter and engraver.

Charles Nicholas Cochin, the ſon, was born at Paris in 1715, and died in the ſame city in 1788. This celebrated artiſt inherited from nature the moſt happy diſpoſitions and talents for the arts of deſign, and ſeveral circumſtances concurred to haſten the developement of his faculties. He was the ſon of Charles Nicholas Cochin and of Marie Madeleine Hortemels, and received from them inſtructions in art, along with the other branches of his education, which was conducted under the paternal roof. He gave many proofs at a very early age of the rapidity of his progreſs in arts and letters. In 1740 he viſited Italy in company with the marquis of Marigny, and in 1758 publiſhed his "Collection of Obſervations on the Paintings and Sculpture which are to be ſeen in the principal cities of Italy." This work was very well received by the impartial part of the public, but the Italians, though delighted at diſplaying their artiſtic treaſures to the eye of ſtrangers, were nevertheleſs indignant that any one ſhould preſume to criticize them. Some Ciceroni have blamed the author for the ſevere ſtyle in which his criticiſms are delivered. But however this may be, the work in queſtion is, even at preſent, deemed the beſt guide to travellers who wiſh to attain a knowledge of the works of art in Italy. An excellent companion to this work is "Obſervations upon the Antiquities of Herculaneum, &c." by M. M. Cochin and Bellicard, which poſſeſſes the advantage of containing a great number of beautiful ſubjects of antiquities engraved with great ſpirit by the authors.

On his return to his native country this artiſt was created a chevalier of the order of St. Michael, deſigner to the king, and ſecretary to the academy of painting. Equally ſkilful as an engraver, and as a deſigner, his works amounted to above fifteen hundred ſubjects, of which one hundred and twelve are portraits en medallion of the quarto ſize, moſt of which were of his friends, and other diſtinguiſhed artiſts and men of letters.

The mode of art which he employed on his plates was chiefly etching, and his etching might be ſaid to conſiſt almoſt entirely of drawing, performed with taſte and freedom, and combined with a degree of picturesque feeling, which perhaps has never been exceeded. His beſt landſcape, fancy, and hiſtorical productions are as follow:

"The Death of Hypolitus," after J. F. de Troy, in folio. "David playing on the Harp before Saul," after Carlo Vanloo, in folio. "Abraham receiving Hagar by the Advice of Sarah," after the ſame. "Grand Views of the Sea-ports of France," after Vernet, etched by Cochin, and finiſhed by Le Bas, fourteen plates of large folio dimenſions. Sixteen large prints, repreſenting hiſtorical ſubjects of the Chineſe empire, deſigned at China, and ſent to Paris by the emperor, to be engraven.

The direction of this national work was committed to Cochin, who diſtributed them, in order to be engraven under his auſpices, to the following artiſts: J. Aveline, Aug. de St. Aubin, Ch. le Bas, J. P. Choffard, N. de Launay, L. Muſquelier, F. de Né, and B. L. Prevoſt. Theſe ſubjects were deſigned by the Jeſuit miſſionaries, the father Attiret, firſt painter to the emperor of China, Damaſcenus Sikelbar, and Caſtiglione. The prints being ſent to China, as they were engraven and wrought off, proofs of them were not to be obtained by the public. Only a ſmall number were reſerved for the royal family, and the king's library, but Helman the engraver executed a few copies of a ſmaller ſize. Cochin likewiſe engraved the following, which are chiefly after his own deſigns. "The Infant Jeſus holding a ſmall Croſs." "The Virgin in the Attitude of a Magnificat." "The ſmall Crucifix, to which the Convulſionaries attributed Miracles." "Lucius Quintus Cincinnatus," drawn from the antique ſtatue, in 4to. "The Conſecration of Louis XV. at Rheims," for the medallic hiſtory by Godenoche, in 4to. "Decoration for the Illumination and artificial Fire Works in honour of the Dauphin, at Meudon, in 1736." Decoration for the Illumination and artificial Fire Works at Verſailles," 1739. "Perſpective view of the Illumination in the Rue Ferronerie, in 1739," all in folio. "Decoration of the Saloon, conſtructed at Verſailles, for the Repreſentation of "The Princeſs of Navarre," a comic piece, in honour of the nuptials of Louis Dauphin of France, with Maria-Thereſa, Infanta of Spain, on the 20th of February 1745." Executed by Slodtz and Perot, deſigned and engraven by Cochin. "Ceremony of the Marriage of the Dauphin with the Infanta of Spain, in 1745," engraven in 1746. "Funeral Obſequies of the Dauphineſs at St. Denis, in 1746." "Funeral Obſequies of the Dauphineſs in the church of Notre-Dame at Paris, 1746." "Funeral Ceremony of the King of Spain, in the Church of Notre Dame at Paris, 1746." "Funeral Ceremony of Catherine Opalinſka, Queen of Poland, in the Church of Notre Dame at Paris," deſigned and etched by Cochin the ſon, finiſhed with the graver by J. Ouvrier, all in folio; and a ſmall plate of a jeweller with a cluſter of precious ſtones, being the firſt plate which he engraved from his own deſign.

The beſt portraits of Cochin jun. are Franciſcus Benallus Tarviſinus, abbax, engraven in 1751. Louis de Boiſſy, of the French Academy. Edme Bouchardon, ſculptor, 1754. Count de Caylus, amateur. The abbé de Chauvelain, counſellor of the parliament. Charles Duclos, hiſtoriographer. Pierre Jeliot, opera ſinger. The ſame portrait finiſhed by A. de St. Aubin. The marquis de Marigny, etched in 1752, under the title Marquis de Vandieres, and finiſhed in 1757 under that of Marigny. Pierre de la Place, of the Academy. The abbé Pommier, counſellor of the Parliament. Jean Reſtout, painter of the Academy. A. L. Seguier, advocate general. The duke de la Valliere, of the Academy of Sciences. Prince de Turenne, amateur.

Of count de Caylus, who lived at the time now under our obſervation, his various antiquarian purſuits, his love of the arts, the ſimplicity of his manners, and his irreproachable morals, we have already ſpoken, (See the article CAYLUS.) His rank and reputation for fine taſte gave a degree of celebrity to his etchings which they do not intrinſically merit, and time, which is ſure to overcome faſhion, has ſince reduced them to the ſtandard of mediocrity. It muſt now be acknowledged that he could not, even with the aſſiſtance of Bouchardon, draw with ſufficient accuracy to etch from the ſculptured gems of antiquity; though in imitating the ſketches of the old maſters, and the groteſque heads of Leonardo da Vinci, he has been far more ſucceſsful.

His prints are in general ſmall, but very numerous. According to Mariette, they amounted to no fewer than three thouſand two hundred ſubjects, of which we ſhall proceed to name the principal. They are commonly marked either with the letter C. or in ſome inſtances C. de C.

Eighty-five plates of heads, after Leonardo da Vinci. Five large plates, after Della Bella. Upwards of two hundred plates from drawings and ſketches by the old maſters, formerly in the cabinet of the king of France. A collection drawn from antique gems by Bouchardon, etched by C. de C., and finiſhed with the graver by Le Bas, on ten quarto plates. Six large plates of mythological ſubjects, compoſed by Bouchardon, etched by C. de C., and terminated

nated with the graver by Et. Feſſard. A collection of heads (conſiſting of thirty of the quarto ſize) from the drawings of Rubens, or Vandyke, or both theſe maſters, in the Crozat collection; and "The Aſſembly of Brokers," a humorous print, in quarto.

The following portraits are alſo from the etching-needle of Count Caylus, namely, Michael Maſciti, in a medallion, dated 1726. The abbé le Gendre. Camille Falconet, a phyſician of Lyons. Polidore da Caravaggio, and Voltaire in the Baſtile; all of them ſmall plates.

Louis Surrugue, the elder, was born at Paris in 1695, and died in the ſame city in 1769. He learned the principles of deſign and of engraving under P. Picart, whoſe manner he ſucceſsfully imitated. His ſtyle is, on the whole, commendable, and he was one of thoſe artiſts who combined with good effect the etching-needle and the graver. Surrugue furniſhed ſome very good prints to the greateſt number of the collections which appeared during his time.

He was a member of the Royal Academy, and engraved portraits and hiſtory with equal ſucceſs. The following are the ſubjects of his principal works:

"St. Marguerite trampling an enormous Dragon under foot," after Raphael. "St Jerome ſitting in the Deſart, in profound Meditation" after Balthaſar of Sienna, engraven by Nicolas Chateau, and retouched by Louis Surrugue. "Jeſus curing Ten Lepers," after Jerome Genga. "Abraham offering up Iſaac," after the celebrated painting of Andrea del Sarto, in the gallery of Dreſden. Theſe four are in folio. "The Nativity of the Virgin," after P. da Cortona, in quarto. "Moſes breaki g the Tables of the Law," after Pouſſin. "Hagar diſmiſſed by Abraham," after Euſt. le Sueur, engraven in 1711. "Protection granted to the Fine Arts," after Le Brun. "Deſcent of Æneas into Hell," after Ant. Coypel. "Economy," after a painting of Chardin, in the cabinet of the king of Sweden, being a companion to "The Amuſements of Private Life," in the ſame cabinet. "Amuſements of Cytherea," after Watteau. A Pair after the ſame: "A Scene in an Italian Comedy," and "A Concert of Muſic." "The Deſire of Pleaſing," after J. B. Pater. "The Pleaſures of Summer," after the ſame. Two ſubjects from the comic romance of Scarron, entitled "Madame de Bouvillon, in order to tempt Fate, bids him ſeek her a Flea;" and "Ragotin eſcaping from a Cheſt," after the ſame painter, and of the upright form. "Diverſions of the Dutch Peaſantry," after D. Teniers, engraven in 1748. "David Teniers cauſing his Wife's Fortune to be told," after the ſame. "Silvia in expectation of her Lover," after a painting of Santerre from an idea of Rembrandt. "The Philoſopher in Meditation," and "The Philoſopher in Contemplation," two ſubjects after Rembrandt. "Venus nouriſhing the Loves," after Rubens, a compoſition alſo engraven by C. Galle, and by H. Watelet. The above ſubjects are all in folio.

Surrugue alſo engraved two portraits, as appears to have been the cuſtom, for his admiſſion into the Royal Academy, of the following artiſts, Louis de Boullongne, the father, painter to the king, after Mathieu. Joſeph-Chriſtophe Veirier, a Provençal ſculptor, relation and pupil of P. Puget, both in folio.

Pierre-Louis Surrugue, the ſon, was born at Paris in the year 1717. He acquired the elements of his art under the paternal roof. His ſtyle of engraving greatly reſembled that of his father; like him he was a member of the royal academy, and like him alſo he engraved both portraits and hiſtorical ſubjects, of which the following are thoſe of moſt importance. Excepting a pair of quarto landſcapes after Teniers, they are all of the folio claſs.

"The Nativity of our Saviour," after the celebrated painting of Correggio, known under the name of la Nuit de Correge. "The Virgin and Child accompanied by St. Jerome, St. Criſpin, and St. Criſpinian," after Guido. "The Judgment of Paris," after H. Goltzius. "The Converſation," and "The Gypſey in Bed," two Flemiſh ſubjects after Teniers, engraven in 1748. "Two Flemiſh Landſcapes," after the ſame, engraven in 1750, in quarto. "Clytie changed into a Sun-flower," after Ch. Coypel. "Orlando learning the Flight of Angelica from the Shepherds." "Deſign of a Saloon at St Cloud, repreſenting the Apotheoſis of Hercules," both from Ch. Coypel. A pair after B. S. Chardin, entitled "The Monkey Painter," and "The Antiquary (an ape) in the midſt of his Curioſities." "The Blind Man," with ſix French verſes, is from the ſame painter.

His beſt portraits are in folio, and are thoſe of Simon Guillain, ſculptor to the king, after N. Coypel, engraven by P. L Surrugue for his reception into the academy in 1747. René Fremin, director of the academy of painting, after de la Tour, engraven by Surrugue the younger for his reception into the academy in 1747. Madame de * * * in a ball dreſs, after Ant. Coypel. This anonymous portrait was falſely underſtood to be that of Madame de Pompadour, but is that of Madame de Mouchi; and Rembrandt the father, painted by the ſon.

Jacques-Gabriel Huquier, the father, was born at Orleans in 1695, and died at Paris in 1772. In conjunction with his ſon, this artiſt etched a great number of prints after Gillot, Watteau, Boucher, and other French maſters. He was a print merchant, and carried on a conſiderable trade, and at his houſe the artiſts and amateurs of Paris were accuſtomed to meet on certain evenings, and converſe for their mutual pleaſure and improvement.

Huquier was a man of taſte, well informed on ſubjects connected with the fine arts, and at his death left an immenſe collection of prints and drawings of great value, which were ſold by public auction. We begin our ſelection of his beſt works, with thoſe which he has engraven after Watteau, which are all of the folio claſs.

A ſet of five plates entitled "The Senſes." A pair of the gardens of Cytherea and Bacchus. The following are alſo publiſhed in pairs, "The Temple of Bacchus," and "The Temple of Neptune." "Apollo," and "Diana as a Huntreſs." "The Faithful Gardener," and "The Ardent Shepherd." "The Cradle," and "The Theatre." "The Triumph of Galatea," and "The Shepherd overtaken by a Storm." "The Emperor of China," and "The Chineſe Divinity." A ſet of four plates of the ſeaſons, expreſſed by Paſtorals; and another ſet of the four elements.

His beſt prints after Boucher are two books of ſtudies, four plates in each. A book of academical figures. Four ſets of Paſtorals, ſix prints in each. Four plates of Chineſe ſubjects;—but Boucher is always temporary or trifling.

From his own deſigns he has engraven one hundred and eight plates, conſiſting of ſix hundred ornamented vaſes, another book of ornaments, and a grand iconology, or collection of allegorical vignettes, repreſenting arts and ſciences, heathen deities, virtues, vices, &c. on two hundred and ſixteen plates; and a collection of antique figures from drawings by Oppenort, whoſe portrait he has alſo engraved.

Gille Edme Petit was born at Paris in the year 1696, and died in the ſame city in 1760. He was the diſciple of Jac. Chereau, and his ſtyle of engraving greatly reſembled that of his maſter. To him we are indebted for a conſiderable number of portraits, of which the following are the princi-

pal, executed with great neatneſs; and, as is believed, almoſt entirely with the graver.

Prince Charles Edward Stuart, from a picture painted at Rome by Dupré. Philibert Papillon, canon of the chapel of Riche, at Dijon. Pierre Bayle, the celebrated critic. Marie de la Fontaine, of La Boiſſiere, after De la Tour. Louis Phillipe, regent of France, after Liotard. Maria Thereſa, queen of Hungary, after Meytens. René Charles De Maupeou, firſt preſident of the parliament, after Chevalier. Armand Jules, prince de Rohan, archbiſhop of Rheims, after Rigaud. Henri-Charles de Pomponne, abbé of St. Medard, after J. B. Vanloo. Jean-Frederic Philippeaux, count de Maurepas, after L. M. Vanloo. Joachim-François-Bernard Potier, duke de Gueſvres, after the ſame, engraven in 1735. Francis I., king of France, after Titian, engraved for the Crozat collection; and Louis XV., king of France, after Carlo Vanloo.

The following are from the pictures of Frere Jean Andre. "The Pilgrims of Emaus." "The Viſitation." "The Virgin with her Roſary." and "St. Catherine of Sienna." The above ſubjects are all in folio.

Pierre Subleyras was born at Uſez in 1699, and died at Rome in 1749. At the age of fifteen he was ſent to Touloufe, and placed under the care of Antoine Rivalz. At twenty-one he viſited Paris, and obtained the firſt prize of the Academy, of which the ſubject was the brazen ſerpent. In conſequence of this, he was appointed by the French Academy to go to Rome, where he remained for ſome time, and completed his ſtudies. The manner of living in this city being agreeable to his mode of thinking, he finally ſettled in it, and eſpouſed ſignora Maria-Felice Tibaldi, a celebrated minature painter. Subleyras compoſed with great facility, and drew correctly. He poſſeſſed a brilliant reputation, though he died at the age of fifty, and the great number of his pictures, which were to be found both in Rome and the other Italian cities, bears teſtimony to his genius, and the fertility of his imagination.

Subleyras etched ſome ſubjects from his own compoſitions; and is among the number of thoſe painters who have handled the etching-needle with great taſte and ſpirit. His choice of ſubjects is excellent.

We may here mention, as favourable ſpecimens of his talent as an etcher, the following prints:

"The Brazen Serpent," for the prize of the Academy. "The Martyrdom of St. Peter." "Jeſus at Supper in the Houſe of the Phariſee, with Mary Magdalen at his Feet." Four ſubjects taken from La Fontaine's Fables.

Bernard Lepicie was born at Paris in 1699, and died in the ſame city in 1755. At his death he enjoyed the title of perpetual ſecretary and hiſtoriographer to the Royal Academy, and profeſſor of hiſtory to the eſtabliſhment for the inſtruction of pupils.

In engraving he appears to have ſtudied in the ſchool of Jean Audran, whoſe ſtyle he ſucceſsfully imitated. His drawing is not very correct, though it muſt be admitted that many of his prints are not deſtitute of merit. He viſited England, being invited hither by Duboſc, and during his ſtay aſſiſted Dorigny in engraving the Cartoons of Raphael at Hampton Court.

In his capacity of hiſtoriographer to the Academy, he publiſhed two works, having for their titles: "Deſcriptions of the Pictures of the King;" and "The Lives of the firſt Painters to the King, from Charles Le Brun, to François Le Moine."

The prints of this artiſt conſiſt of hiſtorical ſubjects, and portraits of the folio claſs, and are principally as follow:

"The Circumciſion;" "Jupiter and Juno;" and "Jupiter and Io;" after Julio Romano. "St. John preaching in the Wilderneſs," after J. Baptiſte Gauli, ſurnamed the Drunkard. "Vertumnus and Pomona," after Rembrandt. "An old Woman telling a young Girl's Fortune." "The Flemiſh Philoſopher," engraven in 1744; and "The Flemiſh Freemaſons in their Lodge," both after Teniers. A pair entitled, "The Game of Cheſs," after Carlo de Moer, dated 1746; and "The Game of Picquet," after Gaſ. Netſcher. Another pair after the ſame, entitled "Love in a City;" and "Love in a Village." "Thalia expelled by Painting," after Ch. Coypel. "The Loves at their Toilette," after the ſame. "Ceres aſleep," after Fr. Boucher. "The Breakfaſt," after the ſame. "Cupid bird-catching," and "Cupid reaping," two prints after the ſame. "A Baſhaw cauſing his Miſtreſs to be painted," after Carlo Vanloo. "Charles I. taking leave of his Children," after Raoux. "Monument to the Memory of Bayle, Locke, and Sydenham," after Creti, Ferraivoli, and Mirandot, conſtituting one of the nine prints engraven in England by Lepicie, and other French engravers.

The beſt portraits by this artiſt are thoſe of Nicolas Bertin, painter to the king, painted by Lien, and engraven by Lepicie for his reception into the Academy in 1740. Louis de Boullongne, firſt painter to the king, after H. Rigaud. Philibert Orry, miniſter of finance, after the ſame. Pierre Graſſin, director general of the mint, after Largilliere. Claude Capperonnier, librarian to the king, after Aved. Antoine de la Roque, an old military officer, repoſing in a landſcape adorned with nymphs and fawns, after Watteau. Charlotte Deſmares, as Thalia, after C. C. (Charles Coypel). Catherine de Seine, in the character of Cleopatra, after Jac. And. Aved. Frances d'Aubigny, marchioneſs de Maintenon, after Mignard. Jean Baptiſte Moliere, after Charles Coypel.

Renée-Elizabeth Marlie, wife of Bernard Lepicie, was alſo diſtinguiſhed as a French engraver. Her beſt works are, "Youth feigning Decrepitude," engraven in 1751. "Benedicite;" and "The laborious Mother," after S. Chardin, two plates. "The Flemiſh Cook," after D. Teniers, engraven in 1748.

Marie Jean Dubos, the pupil of Charles Dupuis, was born in the year 1700. She ſucceſsfully imitated the ſtyle of her inſtructor, and engraved ſeveral plates in the courtly work, which is entitled "Verſailles Immortaliſé," and which appeared at Paris in the year 1720, in two quarto volumes. The following pair of folio prints are alſo from her hand: "A young Girl careſſing a Rabbit," after S. Baſſeporte; and "A Girl with her favourite Cat," after P. P. A. Robert.

Jean Hauſſart, or Hauſſard, was born at Paris in the beginning of the eighteenth century. The time of his death is not mentioned; neither is it known under what maſter he ſtudied, but he imitated, with much ſucceſs, the ſtyle of Benoit Audran. His drawing was correct, and the greateſt number of his prints executed with conſiderable taſte. The productions which do him moſt honour are thoſe which he engraved for the collection of Crozat, among which are the following:

"Jupiter and Semele," after a cartoon of Julia Romano. "The Creation of Eve," after the ſame painter. "Virtue," an allegorical ſubject, conſiſting of five figures, after Siciolante Sermoneta. "Jeſus expelling the Venders from the Temple," after Barth. Manfredi. "Topers aſſembled round a Table;" and "Moſes ſtriking the Rock," both after Fr. Romanelli. "Dives and Lazarus," after Dom Feti. "The Four Ages," deſigned by Hauſſard himſelf. "The Virgin holding the infant Jeſus ſtanding on her Knees,"

in a border of roſe-trees, with the inſcription "Roſa myſtica," de la Foſſe pinx. "The Metamorphoſis of Syrinx," after Jac. Courtin, all in folio.

Jean Charles Flipart, the elder, was born at Paris A.D. 1700, or thereabout, and died in the ſame city, but the time of his death has not been mentioned. His ſtyle is neat, but deficient in the more important requiſites. The two which immediately follow, and which he engraved after Raphael for the Crozat collection, are probably his beſt performances. "The Virgin and Child;" and Jeſus at Prayer on the Mount of Olives;" both ſmall upright folios.

He alſo engraved, but without any conſiderable ſucceſs, "A Magdalen," after Ch. Le Brun; and "Apollo purſuing Daphne," after René Houaſſe, in 4to.

Jean Jacques Flipart, (the ſon,) was born at Paris in 1723, and died in the ſame city in 1782. Never did any artiſt, according to Baſan, poſſeſs more modeſty and diſintereſtedneſs than the junior Flipart, and with theſe qualities were united a conſiderable portion of profeſſional talent. His earlier prints are executed in a comparatively open ſtyle, with few croſſings, but afterwards, adopting the opinion of Watelet, that the white intervals between the lines of an engraving were more or leſs unfavourable to the repoſe of a print, he changed his principle, and began to advance his plates by means of etching, croſſing his work frequently with ſecond and third courſes of lines, and filling up the interſtices which ſtill remained with dots, ſo that upon the varniſh, and before his plates were bit-in, they had a very finiſhed appearance. Had he corroded theſe etchings to a ſufficient depth, he would have ſpared himſelf much time and labour: inſtead of which he bit them in but lightly, and proceeded to finiſh by re-entering his etched lines with the graver. In this manner, however, he executed ſeveral excellent prints which combine good drawing with effective chiaro-ſcuro, and among which the following, which are moſtly of the folio dimenſions, are juſtly held in eſteem:

"A Holy Family," after Julia Romano. "Adam and Eve in the Preſence of the Eternal after their Fall," after Charles Natoine. "Venus preſenting Arms to Æneas," after the ſame. "The young Corinthian," after J. B. Vien. "The Virtuous Athenian," after the ſame, an upright. "The Paralytic Father, ſurrounded and attended by his Children," after the ſame. "The Village Bride," after J. B. Greuze, engraven in 1770. A beautiful compoſition, and finely executed. "The Cake at the Feaſt of Kings," after the ſame, engraven in 1777; a grand compoſition. "The Tempeſt, or a Shipwreck during the Day," after Vernet. "The Tempeſt, or a Shipwreck during the Night," after the ſame, engraven in 1771. Theſe two large prints are ably executed, and produce a grand effect. "Our Lord curing the Paralytics," after Dietrichy. "Bear-hunting," after Carlo Vanloo. "Tiger-hunting," after Boucher, being a companion print to the preceding. "The Combat of the Centaurs and the Lapithæ," after a painting of L. Boullogne, engraved for the reception of Flipart into the Academy.

His beſt portraits are thoſe of Jeanne du Ronceray, wife of Favart, drawn by Cochin, in quarto. Jean Baptiſte Greuze, drawn by himſelf, and engraven by his friend Flipart, in quarto.

Flipart has likewiſe engraven with much taſte ſeveral vignettes and ornaments for books. He had a younger bother, Charles François, who died in 1773, and who executed ſome ſmall prints after Fragonard. Joſeph Flipart, who is believed to have been of the ſame family, was engraving at Venice in 1740, for Wagner.

The only production of his with which we are acquainted is a concert with four Italian verſes, inſcribed Joſeph Flipart pinx. et ſc. Wagner exc.

Laurent Cars was born at Lyons in 1702, and died at Paris in 1771. He was the ſon and pupil of Jean François Cars, who had engraven a few portraits, &c. and when very young, accompanied his father to Paris. At firſt he applied himſelf to painting, but in a very ſhort time relinquiſhed this art, and ever afterwards dedicated his time to engraving, in which he made great progreſs.

Cars has been regarded by Watelet, and other excellent judges, as one of the beſt engravers of the eighteenth century. He executed his prints in a very different, though perhaps not in a preferable ſtyle to that of the preceding age; but though it might not have been equally ſuitable to the paintings, after which thoſe maſters engraved, yet it was naturally ſuggeſted to the mind of Cars by engraving after Le Moine. The pictures of the great maſters of Italy, particularly Le Seur, Le Brun, Mignard, &c. poſſeſſed a degree of harſhneſs which would have been but ill expreſſed by the faſcinating mellowneſs which Cars introduced even into his ſhadows. In the productions of J. Audran, picquancy predominates in the half tints, while in Cars', it is in the ſhadows. His chef d'œuvres are thoſe which he engraved after Le Moine, and eſpecially Hercules with the diſtaff.

The engravings of this very meritorious artiſt are numerous, and in general large. The following are thoſe more particularly worthy the notice of connoiſſeurs:

"The Adoration of the Shepherds," and "the Flight into Egypt," both after Carlo Vanloo. "The Tranſgreſſion of David," after J. F. de Troy. "The Chaſtity of Suſanna," after the ſame. "The Blind Man duped," after J. B. Greuze. "The Mother with Three Children," after the ſame, etched by L. Cars, and finiſhed with the graver by A. D. Jardinier. "Adam and Eve before their Tranſgreſſion," after Fr. le Moine. "Adam and Eve after their Tranſgreſſion," a companion print to the preceding, after Ch. Natoire. "The Bather," a nymph entering the water, after Le Moine, who was alſo the painter of the following eight ſubjects: "Time carrying away Truth." "Hercules ſpinning before Omphale," a diſtinguiſhed piece. "Perſeus delivering Andromeda." "Iphigenia about to be ſacrificed, is reſcued by Diana." "Hercules victorious over the Robber Cacus," painted by le Moine for his reception into the academy. "Cephalus carried away by Aurora." "Jupiter and Europa." "An allegory on the Fruitfulneſs of the Queen." "Louis XV. taken out of the Hands of Women, and placed under the Care of Men," after Fr. Boucher. "Monument in honour of the Duke of Marlborough," after the ſame. "The Fortune-teller." "A Venetian Feſtival," and "An eſcort of Equipages," all after Watteau.

The moſt diſtinguiſhed portraits from the graver of Cars are thoſe of Michael Anguier, ſculptor to the king, painted by Gab. Revel, and engraven by L. Cars, for his reception into the academy in 1733. Armand Gaſton, cardinal de Rohan, after H. Rigaud. Pierre d'Hozier, genealogiſt of France. Maria, princeſs of Poland, queen of France, after C. Vanloo. Louis viſcount d'Aubuſſon, duke de la Feuillade. Gaſpar de Real, Chevalier. François Boucher, firſt painter to the king. Jean Baptiſte Simeon Chardin, painter. Frances Marguerite Pouget, wife of Chardin. Pierre Perault, librarian. Sebaſtian Antoine Slodts. Paul Ambroiſe Slodts. Michael Angelo Slodts. Jacques Germain Soufflot, and Carlo Vanloo painter, all after the junior Cochin; Mademoiſelle Camargo, after Lancret, and Madame Clairon in a dramatic character.

Jean Daulle was born at Abbeville in the year 1703, and

and died in the city of Paris in 1763. He acquired the rudiments of his art in his native city from an obſcure engraver of the name of Robert Hecquet, and afterwards viſiting Paris for improvement; he there ſo far diſtinguiſhed himſelf, as to be admitted a member of the French academy in the year 1742. Strutt ſays he worked entirely with the graver, and his performances ſufficiently manifeſt the great command he had of that inſtrument. His ſtrokes are laid with much freedom, yet without any affectation. They are very clear, and produce a pleaſing harmonized effect. Had his knowledge in drawing been equal to his management of the mechanical part of his engravings, they would have ranked with the firſt performances the world ever produced; and from the French writers we learn that the fate of Daulle was that of too many of the engravers of our own country; he was obliged, in order to obtain a ſubſiſtence, to practiſe that kind of art for which he was leaſt qualified by nature, and neglect that in which he would probably have attained to higher excellence. Watelet praiſes highly his portrait of the counteſs of Feuquieres, who is repreſented holding the portrait of Mignard the painter; and his moſt eſteemed hiſtorical engravings, which are of the folio claſs, are thoſe which follow:

The celebrated recumbent Magdalen of Corregio, engraved for the Dreſden gallery. "Diogenes with his Lantern," after Eſpagnolet. "The Two Sons of Rubens," ſtanding figures, after that painter. "The Quos Ego, or Neptune allaying the Tempeſt," from Virgil, after Rubens, a large plate. "A Charity with Three Children," after Albano. "The Triumph of Venus," after Boucher. A pair of prints dedicated to Madame Pompadour of "The four Seaſons," after the ſame. "The Vengeance of Latona," after J. Jouvenet, engraven in 1762. "Jupiter and Semele," after P. de Mathieu. "The Myſtery of the Roſary," with the inſcription, "Meditez ces Myſteres," after Frere Jean Andre. "The Turk regarding Fiſhing," after Vernet, and from the ſame painter. "The Grecian leaving the Bath." "Occupations in Port," and "The Pilgrimage." "The Death of Abel," after Dietrich, engraven in 1761. "Villagers on the Banks of a River," a landſcape after the ſame. "Repoſe of Venus and the Graces at the Bath," after J. Raoux. "The Dutch Churner," after the ſame. "The Magic Lantern," after M. Pierre. "Love on Foot," after Ch. Coypel. "Jupiter under the Form of Diana, enamoured of Caliſto," after Pouſſin. "La Favart, in the Character of Baſtienne," after Carlo Vanloo.

The moſt eſteemed portraits by Daulle are thoſe of Catherine Mignard, counteſs de Feuquieres, holding the portrait of her father. P. Mignard pinx. J. Daulle, ſc. 1735. His firſt work of importance, Hyacinthe Rigaud ſeated at his eaſel, painting his own portrait, and that of his wife, engraven by Daulle for his reception at the academy, in 1742. Margaret de Valois, counteſs de Caylus, after Rigaud. Claude Deſhais Gendron, doctor of medicine, after the ſame. Charles Edward Stuart, eldeſt ſon of the Pretender, without his name, the head painted by an anonymous artiſt, and the drapery by Rigaud, engraven in 1744. Clementina, princeſs of Poland, (wife of the Pretender,) after David; this and the preceding are both rare prints. François Febure de Lembriere, biſhop of Soiſſons, engraven 1736. François Patot, abbé of St. Genevieve. F. D. Emanuel Pinto, grand maſter of Malta, engraven in 1744. Gerard Moerman, counſellor and ſyndic of Rotterdam, after Perronneau, engraven in 1753. Portrait of Gauſſecourt of Geneva, (which his friend Rouſſeau cauſed to be engraven at Paris,) painted by Nonnotte, engraven by Daulle 1754. Charles-Alexander de Lorraine, after Meytens. Jean Baptiſte Rouſſeau, after J. Aved. Pierre Louis Moreau de Maupertuis, an hiſtorical portrait, after R. Tourniere. Mademoiſelle Peliſier, an opera actreſs, as Flora, after H. Drouais. Buſt of Frederic-Guſtavus III. king of Poland, painted at Dreſden by Silveſtre, engraven by J. Daulle engraver to the king, and Jean Mariette, engraver, after Peſne, all in folio.

Jacques Philippe le Bas was born at Paris in the year 1708, and died there in 1782. He was the diſciple of N. Tardieu, and diſtinguiſhed himſelf at an early period of life by producing a great number of beautiful prints, conſiſting of landſcapes, and of landſcapes peopled with ſmall paſtoral or domeſtic figures, ſuch as thoſe of Wouvermans and Teniers, which depend, for the intereſt they excite, rather upon an animated and expreſſive touch, than upon the anatomical or academical proweſs diſplayed in their outlines.

Watelet endeavours to account for the early and extenſive reputation of Le Bas, than whom no engraver in Europe was better known, by ſuppoſing it to have been owing to the great number of prints to which he affixed his name, many of which he allows were of inferior merit and the work of his pupils. "Fully perſuaded," (he ſays,) "that a very ſmall number of real connoiſſeurs exiſted, Le Bas conceived, that he would be deemed the beſt artiſt who put his name to the greateſt number of plates; and the great reputation he acquired evinced that he had not been deceived. But his fame would have been more laſting, had he acknowledged only thoſe engravings which were begun by his beſt pupils, and which he himſelf terminated. Le Bas, however, merits a diſtinguiſhed rank among thoſe artiſts who have been deſervedly celebrated for their taſte. His finiſhing touch, and piquant, and ſpirited ſtyle, imparted animation and grace even to thoſe prints, which in other reſpects were but of inferior execution. He was the firſt, after Rembrandt, who made much uſe of the dry point, and his pupils have ſince brought the uſe of that valuable tool to ſtill greater perfection.

There is certainly much truth in theſe obſervations of Watelet; Le Bas was probably the moſt manufacturing engraver that had yet appeared in Europe, employing ſome of his pupils entirely upon the ſkies in his plates, others entirely upon trees, others upon etching figures, and ſo forth, and did more than any of his predeceſſors to bring down his art to the level of a trade; but it is alſo to be remarked that he had under his roof ſome pupils, or rather journeymen, of the very firſt taſte and talent, among whom were Aliamet, Ryland, Laurent, and others who are probably ſtill living.

Poor Laurent was an Engliſhman who died in Paris of a conſumption; almoſt the whole of whoſe works appeared under the name of Le Bas. He was a man whoſe chemical knowledge enabled him to improve the etching varniſhes in uſe at the time, and whoſe profeſſional taſte and feeling were of the moſt exquiſite kind. He etched the large boar hunt and hawking ſubject, after Wouvermans; the witch of Endor, after Salvator Roſa, ſome large and fine plates after Berghem, and ſeveral other of the very beſt plates that appear with the name of Le Bas.

Le Bas was a man of ſocial habits and manners, and good addreſs, yet his profeſſional induſtry was great, and the liſt of his works numerous, from which the following are ſelected.

A book containing eight quarto plates of military figures. A book containing eight quarto plates of faſhions; a pair in 4to. entitled "The Villagers," and The "Vintagers,"

a pair

a pair in 4to. entitled "Time ill employed," and "The Lover beloved," with ſome other ſubjects of trifling importance for his own deſigns.

From thoſe of other artiſts he has engraven the portraits of Robert le Lorrain, ſculptor to the king, painted by Drouais, engraven by Le Bas for his reception into the academy in 1741. Pierre-Jacques Cazes, painter to the king, painted by Aved, engraven by Le Bas for his reception into the academy in 1741. A ſet of four plates of the times of the day, after N. Berghem, very fine prints, at leaſt two of which were etched by Laurent. "The Return to the Farm," and "Embarkation of Stores," after the ſame maſter. "The Flanders Courier," a landſcape, after Andrew Both. "Ancient View of the Rhine at Coblentz," after Berghem and J. Both. "Ancient View of the Canal at Amſterdam," after the ſame artiſts. "Agreeable Solitude," after Boucher. "Firſt and Second Views of Beauvais," after the ſame. "Firſt and Second Views of Charenton," after the ſame. "Fiſhmonger of Chevelingue," after P. F. Bout. "Firſt and Second Views of the Environs of Lerida," after B. Breemberg. Two Swiſs views, "The Caſcade of Piſſevache," and "A Part of the City of Fribourg, with the Houſe of the Jeſuits," after the ſame. "Two Views in the Pays-Bas, the "Three Mills," and "The Road to Flanders," after Breughel. Two military views, "Diſtribution of Dry Forage," and "The Removal of a Camp," after J. Chantreau. Four prints after Chardin, "The Morning Toilette." "Study of Deſign." "Good Education," and "Economy." "The Dutch Menage," after Oſtade, engraven in 1771. "Dutch Amuſements," after the ſame. "Grecian Ruins," after Pannini. "Radera near Sans-Souci," after the ſame. "Departure for the Italian Hunt." "An Italian Dance." "Halt of French Troops." "Halt of Swiſs Guards," and "An Encounter of Cavalry," after Wouvermans.

The four following are after Poelenbourg; namely, "The ancient Baths at Vaucluſe;" "Ancient Aqueduct at Preneſte," and a pair of ruined edifices in Etruria. From Pynaker we find a "Landſcape with Cattle," from Ruyſdael, a "Dutch Mill," engraven in 1747, and a pair which are views of Schevelingen and Haerlem, (the latter engraven in 1753,) from Sal. Roſa. "The Augurs," and from Watteau, "The Gamut of Love;" "The Faſhionable Aſſembly;" and "The enchanted Iſland."

Le Bas' engravings after Teniers exceed an hundred, many of which are treated in a taſte peculiarly characteriſtic of that admired maſter. Judgment in finiſhing was the forte of this engraver, and the addreſs with which he rendered what others had done, ſubſervient to a final purpoſe, has not ceaſed to be the ſurpriſe of profeſſional men, who ſtill talk of the magic of Le Bas' finiſhing touch. We cannot of courſe enumerate all the prints that he has produced after Teniers, and believe the following will be found among the beſt:

"David Teniers and his Family." "The Works of Mercy," a large and very fine plate. "The Prodigal Son," a companion print to the preceding. "Flemiſh Rejoicings," a beautiful landſcape, in which Teniers has painted himſelf and family. Theſe four are of very ſuperior execution, and we may add to them his grand views of Flanders, and his beautiful village fetes.

His large works from Wouvermans are alſo of the firſt order, and the chief of them entitled as follow:

"The Pot of Milk;" "The Italian Chaſe;" "The Boar Hunt," engraven in 1741, beautifully etched by Laurent. "Halt of Cavalry;" "Halt of Officers," engraven in 1740, companion to the former. After N. N. Coypel he has engraven a pair, entitled "The Bath of Diana;" and "The Alliance of Bacchus and Venus." Another pair, "Hermitage, two leagues from Fribourg in Saxony;" and "The Environs of Fribourg;" are after Dietrichy. "The Fine Morning;" and "The Beautiful Afternoon;" two landſcapes after C. Dujardin. "Departure for the Chace," is after Ch. Van Falens, engraven in 1742, as are the following pair: "A Hunting Rendezvous;" and "The Fortunate Hunter." After Lancret he has engraven Grandval, a celebrated comedian, and "Gallant Converſation;" the latter for his reception at the Academy in 1743. A beautiful print, "Mademoiſelle Dangueville, as Thalia, ſurrounded by various comic Figures," after J. B. Pater. "The ancient Port of Meſſina," after A. Lorrain. "The Villager's Reward," a rich Italian landſcape, after the ſame. "An Italian Sea-port," after Joſeph Vernet, painted at Rome. From the ſame maſter are, "Setting out to fiſh;" and a ſeries of French ſea-ports, in ſixteen very large prints, begun in 1760, and finiſhed in 1776. Theſe plates were engraven conjointly by Cochin and le Bas, excepting the two laſt, the port of Dieppe, and that of Havre, which were finiſhed by M. Martini in 1780. Two Flemiſh prints, "The Reapers," and "The Reapers' Repaſt," after Michault. Two Flemiſh ſubjects on one plate, "The Pleaſures of Noblemen;" and "The Pleaſures of Peaſants." "The Preaching of St. John in the Deſart," after P. F. Mola. "View between the Hague and Rotterdam," after A. Vanderneer. "Winter Diverſion on the River Schie, near Delft," after the ſame. "Day-break," after Ad. Vandevelde, engraven in 1773; and "The Royal Hunt," after the ſame maſter.

Quintin Pierre Chedel was born at Chalons, in Champagne, in 1705, and died in that province in 1762. He had been a ſtudent in literature in his youth, but having repaired to Paris, inſtead of continuing his literary ſtudies he delivered himſelf up to his natural taſte for deſign and etching, in which he was ſingularly ſucceſsful. He was much employed by the bookſellers, but having injured his health by his great aſſiduity in his profeſſion, he returned to his native province, in order to ſpend the remainder of his days. His works were extremely numerous, a few of which we ſhall only mention. Portrait, in a medallion, of Claude de l'Iſle, hiſtoriographer to the king. Portrait, in a buſt, of Nicolas de la Brouſſe, count de Verteillac &c. The ſix days of the Creation, ſix ſmall prints in the form of vignettes. Fourteen ſubjects from the Old Teſtament, of the ſame form. Series of battles in the form of vignettes, fifty-nine prints. Six ſmall plates, marked "Obſervations Aſtronom." Six ſmall landſcapes numbered, on the firſt is inſcribed "Sejour paſtoral." Six plates of landſcapes, inſcribed to the marchioneſs of Pompadour. Military fetes, dedicated to count Turpin de Ceiſſe, &c. ſix prints. Six beautiful prints numbered, of military events. Two rural prints, *viz.* "The Village Wedding," and "The Country Feſtival." Two prints of ruined edifices, entitled "Ruines de Cumes." Two ruſtic ſubjects, the one repreſenting "A Repaſt," the other "A Dance by Peaſants." Two incendiary ſubjects, "The taking of Troy;" "The Burning of a City." Two landſcapes, "The Neſt," and "The Caſcade." Two prints entitled "Views of the Works of the Bridge of Orleans." Six prints of rock work, under the title, "New Whims." P. Q. Chedel ſculp. aqua forti. "T. Q. Flaminius giving Peace to Greece."

Various ſubjects after different maſters: Two marine prints, entitled "The Fiſhers," after Adam Willaers. Four military actions, entitled "Various Skirmiſhes of Cavalry,"

valry," after Vandermeulen. Four landſcapes adorned with ruins, grottoes, and huts, after Boucher. Four views drawn from nature, by Boucher. Two landſcapes, "View of the Bridge of Lavandieres, in the Æos Païen;" "View of the Devil's Tower, near Blois." Two landſcapes, "The Watering-place for Birds," and "The Dove-houſe," after the ſame. Two landſcapes, "The Fiſher," and "The Ruſtic Bridge," after the ſame. "The Anchorite," a grand landſcape after Boucher. "Hermits in a Deſert," after Pierre. "A Landſcape, in the middle a chateau, and in the fore-ground two cows and a cow-herd repoſing," after the ſame. "A Landſcape, in the middle a Church, and in the fore-ground ſome Cattle," after the ſame. "A marine Piece, in the middle are ſome ruſtic Houſes, on the fore-ground a Man watering his Horſe, and ſome Mariners in port," after the ſame. Two architectural ſubjects, with figures, after Bibiena. Four landſcapes, after Teniers; "Morning Labour;" "The Hour of Dinner;" "The Afternoon;" "The good Night." "The Dawning of Aurora," a beautiful landſcape after Teniers. "General Quarters, adorned with a number of Figures," after Robert Van Hoek. "Sale of Fiſh at Schevelinghe," after Jean Breughel.

Jean Jacques Balechou was born at Arles in the year 1715, and died at Avignon in 1764. "This extraordinary artiſt worked entirely with the graver, and was perfectly maſter of that inſtrument. The clearneſs of his ſtrokes, and the depth of colour which he produced, are far beyond any productions prior to his own. But he did not draw well:" (thus ſays Strutt,) "and on this account" (and on account alſo, we may add, of his not practiſing the art of etching,) "his prints want that freedom, harmony, and correctneſs," which is eſſential to the perfection of engraving. With all his beautiful clearneſs of manual execution, his fleſh appears metallic, his rocks rather reſemble ice, and the foam of his agitated ſea ſome thick and "lazy-pacing" liquid. His moſt juſtly celebrated work is a large ſtorm and ſhipwreck after Vernet, to which theſe remarks are chiefly applicable: but then here is a tempeſt-torn ſky where the dark clouds are admirably engraved, and here is water in its liquid ſtate, expreſſed with ſo much of the truth of nature, that while it left the predeceſſors of Balechou at an immenſe diſtance, has been the ſchool of Woollett, Byrne, and all thoſe who have ſubſequently attempted to diſtinguiſh themſelves in expreſſing the genuine character and appearance of the ſea when agitated by a tempeſt.

Watelet criticiſes our engraver ſomewhat ſeverely for the ſurreptitious brilliancy of execution which he has been too ſolicitous to diſplay, and which in his "Calm," after Vernet, and "St. Genevieve," after Carlo Vanloo, are certainly miſapplied. Good impreſſions of his engravings are, however, highly valued by collectors.

The moſt numerous part of the engravings of Balechou are his portraits: his hiſtorical works, which are of the folio claſs, are but few in number, and are principally as follow:

"Birth," and "Infancy," a pair, after Dandre Bardon. Three plates, of which the titles are unknown to us, after Etienne Jeaurat, "St. Genevieve," after Carlo Vanloo, a large upright. "The Tempeſt," after Joſeph Vernet. "The Calm," after the ſame. Theſe are all in folio, and the two laſt very large.

His beſt portraits are thoſe of Anne Charlotte Gauchier, wife of the painter. A lady ſpinning. Jacques Gabriel Grillet, after Antreau. Charles Henri Friſo, prince of Orange. Dom Philippe, infant of Spain, after Vialy. Charles Porree, a Jeſuit, after Neibſon. Jean Juillienne, a celebrated amateur, holding the portrait of Watteau, after de Troy. The wife of the preceding, from the ſame. Charles Rollin, rector of the univerſity, after Coypel. Charles Coypel, at the age of forty-eight. Henri, count de Bruhl, firſt miniſter of the king of Poland, after Sylveſtre. This is a beautiful portrait, but the plate happening to be injured, has been re-touched. Auguſtus III. king of Poland, after Hyacinthe Rigaud, a whole-length figure accompanied by a little negro. This a chef-d'œuvre of engraving for boldneſs of execution; but the plate having received ſeveral ſubſequent alterations, the beſt proofs are become extremely ſcarce.

Jaques Aliamet was born at Abbeville A. D. 1727, and died at Paris in 1788. He firſt brought himſelf into notice by engraving ſmall ornamental prints for books, uſually termed vignettes; and his reputation was afterwards increaſed by the beautiful prints which he executed after Vernet. He alſo brought to perfection the method of working with the dry point, which he learned from his maſter Le Bas, and harmoniouſly united it with etching and the work of the graver. His ſtyle is peculiarly ſoft, and his touches juſt and expreſſive. He was an enemy to the ſhadows of prints being carried to blackneſs, and compared ſuch prints to thoſe actors, who, overſtepping the modeſty of nature, make the theatre reſound with their abſurd clamour and geſticulations, in order to gain the applauſe of the multitude.

The greater number of the prints of Aliamet conſiſt of landſcapes and ſea-pieces, with ſome few of a different kind.

The liſt of his beſt works follow: being all of the folio claſs.

A landſcape with various figures of men and animals. A pair, very capital and large, of "The Ancient Port of Genoa," and "Purchaſe of a Slave." "Grand Stag Hunt," a beautiful landſcape. "The Brick Kiln," "The Meeting of the Villagers." "The Rural Watering Place." "Village Pleaſures," all after Berghem.

After Wouvermans he engraved "The Spaniſh Halt," and the "Advanced Guard of Hulans." "Riſing of the Moon," after A. Vanderneer. The companion to this print is the moon overclouded, engraven by Zing. "View of Boom on the Rupel," after the ſame. "Two Views of Pont de l'Arche," after Ph. Hackert. A pair of Views of the "Engliſh Garden of Villette," after Jean Hackert, "Winter Amuſements," after Ad. Van de Velde. After Vernet he engraved ſeveral; the names of the chief are, "Stormy Weather." "Foggy Weather." "Italian Labourers." "Conflagration of a Port during the Night." Two views of the Levant. Two views of Marſeilles. A pair of ſea pieces, "Fiſhing with the Line," and "The Return from Fiſhing." And a ſet of the four parts of the day: "Morning," "Mid-day," "Evening," "Night." "The Birth of Venus," after Et. Jeurat. "The Place Maubert," after the ſame. "The Place des Halles," after the ſame. Two of the ſixteen great Chineſe battles were engraven by Aliamet, under the direction of Cochin.

Of the time and place of the birth of Jean George Wille, the preſent writer is not preciſely informed. He was a native of Germany, and eſtabliſhed himſelf at Paris as an engraver of the higheſt repute, about the middle of the laſt century, where, notwithſtanding the juſtly acquired fame of Mellan, Maſſon, Spierre, Nanteuil, Drevet and other ornaments of the French ſchool, he ſhewed that it was poſſible to tranſcend them all with reſpect to beauty and preciſion of manual execution. Strutt ſays of him, that "he excelled

excelled in works which required great execution with the graver; and no one ever ſurpaſſed him in the clearneſs and beauty of the ſtrokes which he laid with that inſtrument. His ſtyle was particularly adapted to expreſs ſilks, ſattins, and all kinds of ſhining draperies; a proof of which is evident in the print repreſenting the death of Cleopatra; the figure of Cleopatra is habited in white ſattin, which the engraver has ſo ſucceſsfully imitated, that the pencil of the moſt able painter could not exceed it."

Not only ſhining draperies, however, but rough and rich objects alſo, ſuch as the carpets, tiſſues, and dead game of Gerard Douw, and the woollen draperies, and leather of Dietrichy, were equally within the ſcope of his powers. His manual powers were indeed ſurpriſing. The graver was a ſimple and very ancient inſtrument. Centuries had looked on, while thouſands of artiſts had tried their ſkill with it, yet it remained for the accurate eye, and firm, delicate, and ſteady hand of Wille, to render it ſubſervient to the expreſſion of the textures of all the various ſubſtances that nature has produced, or art has interwoven.

From this general deſcription of the perfections of the art of Wille, however, ſome abatement ſhould be made; at leaſt certain exceptions; the concomitant errors of human nature ſhould be pointed out to thoſe who might elſe be in danger of having their taſte led away by indiſcriminate admiration. The mathematical preciſion of Wille was far better adapted to expreſs the poliſh and regularity of art, than the wild and rugged ſurfaces in which nature more frequently delights; and even his fleſh, which it muſt neceſſarily be of cardinal importance to expreſs well in every hiſtorical work, when compared with that which is ſo admirably characterized in the beſt works of Bartolozzi and Strange, will appear deficient in that ſoft firmneſs, and delicacy of texture, which diſtinguiſhes it from all other ſurfaces whatever.

Wille was a member of the French Academy, and engraver to the king, honours which he richly deſerved; he taught ſeveral pupils, of whom the preſent writer was informed by one, (the late Mr. Byrne, who ſtudied under him for a while,) that he uſed, for moſt purpoſes, very ſquare gravers, which is contrary to the opinion that is generally entertained. He died lately at Paris, having ſurvived the troubles of the French revolution, at a very advanced age.

To know his own talent, and to be ſurrounded by ſuch circumſtances of patronage and opportunity as enables him to uſe it moſt effectually for the public advantage, does not often fall to the lot of an engraver. Wille enjoyed theſe benefits, and employed the greater part of his time in diffuſing through Europe, along with his own, the fame of Gerard Douw, Dietrichy, Terbourg, Netſcher, Metzu, and ſuch other maſters as are celebrated for the beauty of their execution, and the charms of their chiaro-ſcuro.

Among his beſt performances may be reckoned "The Death of Cleopatra," after G. Netſcher. A pair of uprights after Gerard Douw, entitled "La Menagerie Hollandoiſe," and "La Liſeuſe." "The Good Friends," after Ad. Oſtade. "Paternal Inſtruction," and "The Dutch Gazette," from Terbourg. "La Cuiſiniere Hollandoiſe," after Metzu, and "La Tricoteuſe Hollandoiſe," after Fr. Mieris. "The Inattentive Obſerver" is from the ſame maſter. "The family Concert," and "The Little Muſician," are both after Schalken, and the above are all of the folio claſs. Of a larger folio ſize, are "Sarah introducing Hagar to Abraham," after Dietrichy. And from the ſame painter, "The Strolling Muſicians," and "The Reciprocal Offer," a pair, the former of which is the moſt celebrated; it is dedicated to Frederic Auguſtus, elector of Saxony, and the firſt impreſſions are known from thoſe ſubſequently taken, by the word "Electorale" being omitted in the dedication.

"Maternal Care," "Maternal Delight," and "The School Miſtreſs," are from the pictures of the junior Wille; and "The Little Scholar," companion to the latter, from J. E. Schenau. Theſe alſo are in folio.

From the younger Wille, he has alſo engraven a large plate, entitled "Le Maréchal des Logis," which repreſents the courage of Louis Gillet in reſcuing a young girl from the power of two robbers; and one of his celebrated, though by no means the beſt of his hiſtorical engravings, is "The Death of Mark Antony," after Pompeo Battoni.

Wille's portrait was engraven after a picture by his ſon, by his pupil P. C. Ingouf, and in his own ſtyle. The portraits from his own graver are numerous, and among the beſt are reckoned thoſe of Madeleine de Scuderie, and Nicholas de Catinat, marſhal of France, both eſteemed chef-d'œuvres of the maſter, and after Eliz. Cheron, in 8vo. Henry Benviſt, a rare print in quarto. Franciſcus Chicogneau, regi a ſanctioribus Conſiliis archiatrorum Comes, after Le Sueur. Bernard Belidor, after Vizé, engraven in 1754. Proſper Cardinalis Columna de Sciarra, after P. Battoni. All in quarto.

The following are all of the folio claſs: C. E. Briſeux, architect, from the life. Marguerite Eliz. de Largilliere, from a picture by her father. Eliz. de Gouy, daughter of H. Rigaud, from a picture by her father. Joſeph Parrocel. Jean de Boullogne, comptroller-general of finance. Charles Louis Auguſtus Fouquet de Belleiſle, and Maurice of Saxony, marſhal of France, all after Joſ. Parrocel. Woldemar de Loevendal, marſhal of France, after de la Tour. J. B. Le Moine, after J. G. Heilmann. Frederic II. king of Pruſſia, after Peſne, a celebrated print. Hieronymus von Erlach, after Ruſca. Franciſcus Queſnay, after J. Chevalier. Jean Battiſte Maſſé, after Tocque. Louis Philippeaux, comte de St. Florentine, ſecretary of ſtate, &c. &c. is eſteemed one of his beſt portraits, and Abel François Poiſſon, marquis de Marigny, after Tocque, was engraved for his reception into the French Academy.

We have now brought down our account of the French School of Engraving to a period, beyond which, if we were to proceed, we muſt ſpeak of the merits and demerits of living artiſts. The critics and literati of France have with reaſon regretted the decline of French engraving, ſince the era when all Europe was gazing at the conſtellation of art which ſhed luſtre over the reign of their fourteenth Louis. A few bright but ſcattered rays in Wille and his diſciples have gleamed over the metropolis, but a diſtinguiſhed member of the National Inſtitute has within theſe few years acknowledged and lamented that England had borne away the palm of engraving; that the era of French glory in this art was no more; that the indifference of the ancient government towards the art, the want of encouragement and patrioiſm, without which the grandeſt conceptions are unavailable; the abſence of emulation, the neceſſity of gaining a livelihood, which renders the ingenious artiſt a ſlave to the caprices or cupidity of the dealer; luxury itſelf which corrupts taſte, and the falſe ſplendour which leaves ſimplicity and beauty in the ſhade, have all concurred, he ſays, to reduce the art of engraving to its preſent woeful ſtate. Along with this plaint, a plan for renovating the art was ſubmitted to the Directory by Monſ. Guyton, which we believe has never been attempted to be put in execution. Other and more efficient plans will doubtleſs ſucceed the preſent war,

if they be not organizing even now, of which let England liberally beware; for among the men of talent whom the revolution has ſpared, Berthaud, Bervic, Denon, and perhaps others of whom future Cyclopedias ſhall ſpeak, remain to their country.

FRENCH *Silk*. See SILK.

FRENCH *Town*, in *Geography*, a town of America, in Cecil county, Maryland, on the E. ſide of Elk river; 1 mile S. of Elkron, from which it is ſeparated by Elk creek. Elk ferry is 6 miles below this.

FRENCH *Verſions of the Bible*. See BIBLE.

FRENCH *Weights*. See WEIGHTS.

FRENCHMAN. See FRANCIGENA and ENGLECERY.

FRENCHMAN'*s Bay*, in *Geography*, a bay of America, which lies on the ſea-coaſt of Lincoln county, in the ſtate of Maine, and is formed by Mount Deſert iſland on the weſt, and the principal of Goldſborough townſhip in the eaſt. It has an inland communication round Deſert bay with Blue-hill bay.—Alſo, a bay on the S. coaſt of the iſland of Jamaica between Great Pedro bay and Starvegut bay.

FRENCHMAN'*s Creek*, a creek of Upper Canada, in the county of Lincoln, which diſcharges itſelf into the river Niagara, in the townſhip of Bertie, a few miles below Fort Erie.

FRENCHMAN'*s Key*, a ſmall iſland on the Spaniſh Main. N. lat. 12° 16'. W. long. 82° 51'.

FRENEASE, LAKE, a large collection of water, through which St. John's river in New Brunſwick paſſes.

FRENICLE DE BESSY, BERNARD, in *Biography*, a mathematician, the intimate friend of Des Cartes, Fermat, and other learned men his contemporaries, flouriſhed in Paris in the 17th century. He was an expert mathematician, and was choſen member of the French academy of ſciences in 1666. The memoirs of that learned body he furniſhed with a number of ſcientific pieces. Among theſe is one entitled "A method of reſolving problems by excluſions:" and alſo "A treatiſe of right-angled triangles in numbers:" "A ſhort treatiſe on combinations:" "Tables of magic ſquares." In the well known work, entitled "Commercium Epiſtolicum de Quæſtionibus quibuſdam Mathematicis," printed at Oxford in 1658, the reader will find ſome of Frenicle's letters. He died in 1695. Moreri.

FRENTANA REGIO, in *Ancient Geography*, Hither Abruzzo, a country of Italy, bounded by the Tiſconus on one ſide, and by the Aternus on the other.

FRENTANI, a people of Italy, N.E. of Samnium, along the Adriatic gulf; their principal towns were Auximum and Larinum.

FRENUM, or FRÆNUM. See FRÆNUM.

FRENZANO, in *Geography*, a town of Italy, in the department of the Mela; 8 miles W.S.W. of Breſcia.

FRENZY, and FRENETIC. See PHRENZY, and PHRENETIC.

FRERE, CAPE, in *Geography*, a cape on the E. coaſt of the iſland of Martinico.

FREREN, or VREREN, a town of Germany, in the county of Lingen; 6 miles S. E. of Lingen.

FRERET, NICHOLAS, in *Biography*, was born at Paris in 1668; he was educated for the profeſſion of the law, and in compliance with the wiſhes of his friends, he entered upon the duties of an advocate, but without intending to devote his talents to the buſineſs. His favourite ſtudies were hiſtory and chronology, which he purſued with ſo much ardour and ſucceſs, that he obtained admiſſion into the Academy of Inſcriptions at the early age of twenty-five, and immediately ſignalized himſelf by a "Diſcourſe on the origin of the French." This diſcourſe was too bold for the times in which he lived, and in conjunction with ſome imprudent language on the miſunderſtanding between the princes of the blood and the regent, cauſed him to be impriſoned in the Baſtile. During his confinement he was a conſtant reader of Bayle, imbibed all his ſceptical principles, and almoſt committed his works to memory. After his liberation he publiſhed ſeveral pieces, which exhibited profound learning, and much curious diſcuſſion. He wrote with perſpicuity and order; his "Letters from Thraſybulus to Leucippus," and the "Examination of the Apologiſts of Chriſtianity," are deeply tinged with ſceptical tenets. Many of his pieces were of a lighter deſcription, as the preface, notes, and part of a tranſlation of the Spaniſh Romance entitled "Tirante the White." He died in 1749.

FRERON, ELIE CATHERINE, was born at Quimper in 1719. He entered very young among the Jeſuits, with whom his literary taſte was formed, but in 1739 he quitted them, and became a coadjutor of the abbé Fontaines in his periodical publications. (See FONTAINES.) He then publiſhed a ſmall critical journal of his own under the title of "Lettres de Mad. la Compteſſe," 1746, in which he treated with freedom the literary reputation of ſome contemporary authors who had ſufficient influence to procure the ſuppreſſion of his work. It re-appeared in a few years under a different title, *viz.* "Lettres ſur quelques Ecrits de ce Tems," and was well received and liberally ſupported. Thirteen volumes being publiſhed, it was dropped, and a new one began, entitled "L'Année Litteraire," which he continued till his death. Freron had the misfortune of uniting againſt him ſome of the principal writers of the day, among whom was Voltaire. Freron had long carried on a warfare againſt this popular author without provoking his diſpleaſure. A ſevere criticiſm upon his comedy of "La Femme qui a Raiſon," excited the wrath of the dramatiſt, and never after this did he omit an opportunity of throwing odium and contempt on Freron and his works. He was willing however to do homage to his talents and to his taſte as a writer. He died in 1776. Beſides his periodical works he publiſhed "Opuſcules," in three volumes 12mo. conſiſting of pieces in proſe and verſe. He wrote likewiſe, "Les vraies Plaiſirs, ou les Amours de Venus et Adonis," tranſlated from the Italian. He began a tranſlation of Lucretius. Freron was pleaſant and eaſy in his manners, fond of ſociety, and given to diſſipation.

FRESCA, CAPE DEL, in *Geography*, a cape on the W. coaſt of Solfara. N. lat. 39° 45'. E. long. 8° 28'.

FRESCATI. See FRASCATI.

FRESCO PAINTING is a peculiar mode of practice in that art, and is performed by employing colours mixed and ground with water upon a ſtucco, or plaſter, ſufficiently freſh and wet to imbibe and embody the colours with itſelf. The term freſco, as applied to painting, is ſaid to have been adopted becauſe the practice of it is uſed in the open air; "Andare al Freſco," ſignifying "to take the air," or "walk abroad in the air:" but it ſeems more probable that another meaning of the word freſco has given riſe to this particular adoption of it, *viz.* new or freſh, relative to the ſtate of the plaſter in which it is wrought. Vitruvius (l. vii. cap. 4.) calls it "Udo tectorio." It is very ancient, having been practiſed in the earlieſt ages of Greece and Rome.

The theory of the art of painting extends its principles to all modes of execution, becauſe theoretic rules are drawn from nature, which is the object of all imitation, and are independent of the means employed in producing the intended

intended effect. We ſhall therefore only treat in this place of the mode of execution, and materials adopted in freſco paintings.

Previouſly to their being executed in any place, a careful examination ſhould be made of its fitneſs to receive them. It is neceſſary that the artiſt ſhould be aſſured of the perfect conſtruction of the walls, or cielings, on which he intends to employ his genius, and intruſt his reputation; above all, he muſt be careful to make it ſecure from damp.

Satisfied with the conſtruction of the wall, it is then neceſſary the artiſt ſhould ſee to the proper management of the firſt layer of plaſter with which it is covered. The materials employed for building in different countries will vary according to the nature of thoſe moſt eaſy to be obtained: of courſe, it will be neceſſary to adopt means for rendering thoſe not perfectly proper in themſelves to receive freſco painting, more ſo by artificial means. The one beſt calculated to hold the plaſter perfectly is brick; both on account of its abſorbing quality, and from the ſmallneſs of the ſize of the bricks cauſing a number of interſtices between them; which irregularity in the ſurface greatly aſſiſts in retaining it in adherence. A wall built of rough ſtones full of holes may alſo be relied upon as a good foundation for freſco; but if, inſtead of that, it be conſtructed of ſmooth or poliſhed ſtones, it will then be neceſſary to render it uneven by making holes in it, faſtening nails, and ſmall wedges of wood which will hold the plaſter together, and prevent its falling off. Theſe precautions are of the utmoſt conſequence to prevent the danger of its bending or cracking, which the leaſt alteration that happens to the materials, or even the change of weather, producing alternately wet or dry, may occaſion.

The firſt layer of plaſter may be compoſed of well-waſhed chalk made into a cement with pounded brick, or river ſand; which laſt is better, being rather the coarſeſt, and producing thereby a roughneſs of ſurface which will better retain the ſecond coat.

Perhaps the tarras now in uſe, which is compoſed of pounded ſea ſand and chalk or lime, would be better ſtill. The ancients had certainly a better compoſt for this purpoſe than is at preſent known; witneſs that which ſtill covers various of their buildings; particularly the aqueduct they conſtructed near Naples, and the walls of the ruins of Herculaneum.

Before the ſecond layer is given, it is proper to wait till the firſt be perfectly dry, on account of a diſagreeable and noxious vapour which iſſues from the lime in drying; but where it is ſo, and you proceed to give it the ſecond coating upon which the painting is done, it muſt be wetted with water, that the two may more completely incorporate. This layer, which requires to be more carefully prepared than the firſt, is made by mixing river ſand of an even and fine grain with chalk, which has been burnt a twelvemonth before, and expoſed to the air, as by that means the artiſt may be more ſure of its general decompoſition and freedom from ſtony parts.

It requires conſiderable ſkill in the perſon who prepares this ground to lay it perfectly even, and be careful in judging the quantity proper to be laid on at once, which ought not to be more than the painter can cover and completely finiſh in a day; and it requires great ſkill and activity to ſpread, to clean it from lumps, and to poliſh it evenly, ſo as to receive the painting with the promptitude requiſite to leave the artiſt as much time as poſſible, or as he may have occaſion for. The painter however ſhould himſelf ſuperintend this part of the proceſs, for he alone can judge properly as to the rapidity with which he can labour, or the advantages he may make of accidental occurrences.

The operation of laying on the ground is performed with a trowel; and in doing it, care muſt be taken to clean it properly, that the ſurface may be even, particularly in thoſe parts moſt expoſed to view. The concluſion of the maſon's labour is poliſhing to receive the painting. This is done by applying a piece of paper on the ſurface, and paſſing the trowel over it; it is very neceſſary that this ſhould be well done, for ſmall inequalities in the ſurface might, in certain views, produce great irregularities in the drawing of the work.

When the ſecond ground is thus prepared, cleaned, and poliſhed, in the quantity, and on the part of the wall which the artiſt requires, he begins to trace his deſign upon it, and proceeds to the colouring of it; completely covering the quantity prepared, and finiſhing ſo much of the picture in the courſe of the day, in ſuch a manner that he may not have occaſion to re-touch it when the ground is dry. This peculiarity is the characteriſtic diſtinction of painting in freſco, which, by this mode of operation, is incorporated with the mortar, and drying along with it, becomes extremely durable, and brightens in its tones and colour as it dries.

From the neceſſity there is in the progreſs of this ſtyle of art, that it ſhould be executed with rapidity, and from the impoſſibility of retouching it without injuring the purity of the work; the artiſt, unleſs he be endowed with very extraordinary powers of imagination and execution indeed, is obliged to prepare a finiſhed ſketch of the ſubject, wrought to its proper hue and tone of colour, and ſo well digeſted, that there may be no neceſſity for making any eſſential alterations in the deſign. This, which is a very uſeful mode of proceeding in all hiſtoric works of painting, is abſolutely indiſpenſible in freſco, to thoſe who are not determined to give the rein to their ideas, and leave as perfect whatever may firſt preſent itſelf. There is no beginning in this, by drawing in the whole of the parts at one time, and correcting them at leiſure, as is the cuſtom with oil painters, who may therefore proceed to work without a ſketch; here all that is begun in the morning muſt be completed by the evening; and that almoſt without ceſſation of labour, while the plaſter is wet; and not only completed in form, but alſo, a difficult, nay almoſt impoſſible taſk, without a well prepared ſketch, muſt be performed, *viz.* the part done in this ſhort time muſt have ſo perfect an accordance with what follows, or has preceded of the work, that when the whole is finiſhed, it may appear as if it had been executed at once, or in the uſual mode, with ſufficient time to harmonize the various forms and tones of colour. Inſtead of proceeding by ſlow degrees to illuminate the objects, and increaſe the vividneſs of the colours, in a manner ſomewhat ſimilar to the progreſs of nature in the riſing day, till at laſt it ſhines with all its intended effect, which is the courſe of painting in oil; the artiſt working in freſco muſt at once ruſh into broad daylight, at once give all the force in light and ſhade and colour, which the nature of his ſubject requires, and this without the aſſiſtance (at leaſt in the commencement) of contraſt to regulate his eye; ſo that here, as has been ſaid, a well digeſted and finiſhed ſketch ſeems indiſpenſibly requiſite.

The ſketch being completed, the next proceſs is to prepare a cartoon or drawing of the deſign on paper paſted together to the ſize of the intended freſco. This cartoon ſhould be perfected in the out-line to ſave time, and the artiſt has then nothing to do but to trace the line of the figures or other objects which the deſign may be compoſed of, on to the plaſter, by either pricking with a pin through the paper, or by paſſing a hard point over the lines of the

cartoon. By this means he ſaves himſelf the trouble of drawing the figures, and alſo the time which would be required for doing it, and proceeds at once to the painting, to facilitate the execution and enſure the ſucceſs of which ſeveral precautions are requiſite.

The colours being ground fine in water, and the teints moſt likely to be employed largely compoſed, they ſhould be arranged in pots or baſons, and ſeveral pallettes with raiſed edges ſhould be ready at hand to work from, and aſſiſt in compounding the varieties of hues neceſſary for producing brilliancy and harmony. A few pieces of tile or brick, or of any abſorbent ſtone, ſhould alſo be provided to prove the teints upon, becauſe all colours ground in water become much lighter when dry, than they appear when wet. To be certain therefore of their hue, before he begins to uſe them on the picture, and to avoid the trouble and neceſſity of much changing or labouring them, (as the painters term the blending of colours,) the artiſt ſhould apply ſome of each teint with his bruſh to the dry brick, &c. which, abſorbing the water, the colours immediately appear very nearly of the ſame hue they will be of when the freſco is dry. Hence he may proceed with great ſecurity in his work, and is ſure to have it much more freſh and vigorous in effect, than it would be if much labour had been employed to obtain the tone on the wall.

It will be requiſite alſo to have at hand a vaſe or baſon of water, or a wet ſponge, and to take care not to begin to paint till the layer of mortar is hard enough to reſiſt the impreſſion of the finger: otherwiſe the colours would ſpread upon it, and prevent all poſſibility of neatneſs or clearneſs in the execution, which ſhould be effected with great rapidity and lightneſs of hand.

With reſpect to the colours employed *in freſco*, they are fewer in number than thoſe which may be uſed in oil painting, on account of the combined action of the lime, and the air upon the component parts of many of the latter. Thoſe moſt generally in uſe are the following, *viz.*

Lime White.—This, when made of well waſhed burnt chalk or lime, is the beſt and moſt ſimple white that can be uſed; it mixes freely with all the other colours, and works in itſelf with a full body. The preparation of it requires, that the chalk ſhould be ſlacked a twelvemonth before it is uſed, or at leaſt ſix months. It ſhould then be diſſolved in common water and poured carefully off, (after letting it fall ſome ſhort time,) into a veſſel to ſettle.

Another white is made by mixing one third of white marble powder with two thirds of chalk; but it muſt be uſed with caution, as it is apt to change. If the proportion of marble duſt be too ſtrong for the chalk, it will become black. The artiſt would therefore do well to confine himſelf to chalk white, provided it has been well prepared and kept a long time. As this however has frequently been uſed, we deemed it proper to be mentioned that artiſts may, if they chooſe, make experiments upon its nature, and endeavour, if they find any peculiarly valuable quality in it, to inſure its continuance in clearneſs and perfection.

Egg-ſhell White.—There is alſo a third white made of egg-ſhells, which, though it has not the full texture of the chalk, is yet very clear and good for uſe in freſco. It is made by boiling egg-ſhells in water with a little quick lime. They are then put into a pot and waſhed with pure water, then pounded fine, waſhed again till no teint is given to the water, and then ground by the muller and ſtone to the degree fit for uſe; it is afterwards formed into little cakes which are dried in the ſun. Care muſt be taken not to let the powder of the ſhells remain too long in the ſame water, as it will exhale a fœtid vapour almoſt inſupportable, which cannot be diſſipated but by roaſting it in a cloſe veſſel well luted.

Red—produced by burnt vitriol, in colour approaching to Indian red, and ground in ſpirits of wine, acts well with the lime, reſiſts the action of the air, and mixes cleanly with the other colours. This forms an excellent preparation to receive the bright red of cinnabar or vermilion, when the whole wall is covered.

Colours of earthy textures, ſuch as the ochres, when burnt or not burnt, umber, both raw and burnt, Spaniſh red, verd de Verona, Venice black, and blue black, made by bruiſing vine ſtalks, or ſhells of peach-nuts, are all excellent for the purpoſes of freſco painting.

Of Blues,—the beſt is the ultramarine, as it never ſuffers any change. Smalt or enamel blue is good as to preſerving its tone, and, if uſed early in the work, will adhere; but if the ground ſhould become too dry before it is uſed, it is apt not to incorporate ſtrongly with it, but to come off on the leaſt friction.

White lead, lake, verdigreaſe, maſticott, Naples yellow, the orpiments and bone black, are all unfit for this purpoſe, being liable to change.

This kind of painting, when carefully executed, is of all others the moſt durable, and therefore the moſt proper to be employed in adorning public buildings. The uſe of it for this purpoſe appears to be very ancient. Norden ſpeaks of paintings in Egyptian palaces 80 feet high, which Winkelman quoting, concludes they were in freſco, from the deſcription given of the prepared grounds, and of the manner in which the colours appear to have been uſed. And all the paintings found at Herculaneum, at Portici, and at Rome, of ancient date, are of the ſame materials. No other kind of painting would ſo effectually have reſiſted the action of the air for ſo great a length of time, and more particularly the exceſſive aridity thoſe of Herculaneum muſt have endured, being ſhut up entirely from the light, and amidſt glowing embers from Veſuvius, which of courſe muſt at firſt have cauſed an intenſe heat around them. That however, in one point of view, was favourable to the preſervation of thoſe that eſcaped its immediate action; for damp is the moſt powerful deſtroyer of them, againſt which no caution taken can make them too ſecure. In this caſe of Herculaneum, it muſt have been effectually excluded, firſt by the heat of the aſhes, and afterwards as the ſtratum of thoſe aſhes was ſo thick, water from above could not penetrate ſo low as to the pictures, particularly after the upper part was covered with the cloſe cake formed by the decompoſed parts on and near the ſurface.

In ordinary ſituations, the choice of materials is the moſt important part; that the durability of the work may be ſecured, particularly the preparation of the ground, and of the wall, to cauſe it to adhere.

Freſco painting is, or rather has been, chiefly employed in palaces, temples, and other public edifices. For large and important places no other kind of painting is ſo good. As the artiſt is obliged, from its nature, to proceed with rapidity in its production, it has neceſſarily more ſpirit and vigour in the execution, than paintings in oil, which may be repeated, and re-touched, as often as the artiſt fancies he can improve, or heighten, their effect. In freſco there is not time to meddle and diſturb the freſhneſs of the colour, or the fullneſs and freedom of the touch. But there can be no minute detail of forms, or extenſive variety, in the gradation of teints; the beauties of neatneſs, and delicacy of finiſhing, make no part of the excellencies of this branch of the art; it will not bear the cloſe examination which well finiſhed pictures in oil do; there is ſomething dry and rough

in

in its appearance, unpleaſing to the common obſerver, on too cloſe an inſpection. It lacks the full rich ſweetneſs of hue and texture which oil paintings poſſeſs; and though it has more freſhneſs, and retains it; yet from the confined number of colours which can be employed in it, it is not equal to oil in the perfection of the imitation of nature.

Whoever ſeeks to be pleaſed with freſco painting, muſt learn juſtly to eſtimate the beſt, and not the moſt agreeable qualities of the art. Character, contour, expreſſion, are within its powers; and are the points which the great artiſts who practiſe it, knowing its limits, will endeavour moſt to exhibit in their productions. Harmony of colouring, chiaroſcuro, and the minute graces of execution, have never yet been rendered in it; or but very partially in compariſon with works in oil.

In the early part of the reſtoration of painting, a ſpecies of freſco was the only mode of practiſing the art in uſe. A ground of chalk was prepared on tablets of wood, and the colours laid on it, ground and mixed in water only, or with ſome gluten ſoluble in it. The ſurface of the picture was afterwards covered with a varniſh, to ſecure it from rubbing, and to give the teints more force and luſtre.

The principal works that have been produced in freſco, are the ſeries of biblical and evangelical hiſtoric pictures which adorn the walls and cieling of the chapel of Sixtus V. at Rome, by M. A. Buonarotti. The chambers of the Vatican, known by the name of the Stanze of Raphael; which conſiſt principally of religious hiſtories, interſperſed with ſome legendary tales relative to the popes; and the cupola of the duomo of Parma, or church of St. Giovanni in that city, by A. Corregio. It repreſents the aſcenſion of the Virgin amidſt a choir of angels, and with a number of figures of ſaints below regarding it. One beautiful and grand work, by Daniel Ricciarelli, commonly called Da Votterra, at the altar of the church of Trinita da Monte, the ſubject of which is taking Chriſt down from the croſs, is ſaid to have been deſtroyed by the French, in their endeavours to move it to France. They had ſucceeded in ſeparating it from the wall on a perpendicular ſcaffold; but in doing it, they ſo weakened the wall, that in the night the roof fell in upon the picture, and broke it to pieces. Such at leaſt is the report of its fate, which in the preſent unſettled ſtate of the continent, there are no means of decidedly aſcertaining the exact truth of. Dorigny has engraved a large print of the deſign: and the picture has been thought ſo well worthy of attention, that an infinite multitude of copies have been made of it, either for improvement, amuſement, or profit.

Painting in freſco is not much practiſed now. The want of experience neceſſarily produces a want of ſkill. None but thoſe poſſeſſed of large fortunes can be expected to call for it, and without being ſpecially employed in it, no artiſt can be expected to practiſe it. The uſe of it would perhaps not be ſo ſecure here as in Italy, as the ſeverity of froſt, and the dampneſs of the air, might prove injurious to its exiſtence.

Vaſari, however, gives the moſt powerful reaſon for its diſuſe: he ſays, "many of our painters excel in oil and water colours, and yet fail in freſco; becauſe, of all kinds of painting, this requires the greateſt ſtrength of genius to execute; great reſolution and great knowledge to give every ſtroke its juſt character, and to employ them with expreſſion and propriety." If in the period wherein he lived, and he died not till 1578; if in that period, when ſo many great men of ſuperlative genius flouriſhed in the art of painting, few could be found either ſkilful or hardy enough to undertake works in freſco, we cannot be ſurprized that it is not now practiſed largely, when the taſte of the time, delighting in prettineſſes and trifles, does not call for ſuch repreſentations of ſublime conceptions, nor the grandeur of ſtyle in art ſought for and practiſed when Vaſari wrote. See Watelet, Vaſari, Encyclopedie François, Vitruvius.

FRESCOBALDI, GIROLAMO, in *Biography*, the greateſt performer on the organ and harpſichord, and the beſt compoſer for thoſe inſtruments that Italy could boaſt during the ſeventeenth century, was a native of Ferrara, but went early in his life to Rome with his maſter Milleville, where he was elected organiſt of St. Peter's church. All the muſical writers of Italy have celebrated his talents; and his works, which ſtill remain, are indiſputable vouchers of the truth of their encomiums. Quadrio ſays, that early in his youth, as a ſinger, he delighted every ear, and was praiſed by every tongue in the principal cities of Italy. But his chief excellence conſiſted in compoſing and playing on the organ and harpſichord, for which he became ſo renowned, that his works, both printed and manuſcript, were in the hands of all profeſſors, and collectors of muſical compoſitions. The emperor Ferdinand III. ſent Froberger, a young German of promiſing genius, to Rome, on purpoſe to receive inſtructions from Freſcobaldi; by which he profited ſo well, that he was appointed imperial organiſt on his return. According to Della Valle, Freſcobaldi was living in 1641. His firſt work, entitled "Ricercari e Canzoni Franceſe, fatte ſopra diverſi oblighi in Partitura, libro primo, 1615," contains the firſt compoſitions we have ſeen printed in ſcore, and with bars. They are likewiſe the firſt regular fugues that we have found upon one ſubject, or of two ſubjects carried on at the ſame time, from the beginning of a movement to the end. Ricercari and fantaſie preceded ſonatas and concertos, and were the firſt compoſitions expreſsly made for inſtruments, after the invention of counterpoint. The fugues of Freſcobaldi have great merit, if we conſider the ſtate of inſtrumental muſic at the time they were produced: the ſubjects are marked, the harmony pure, and the ſtyle chaſte and clear. Freſcobaldi's maſterly and pleaſing fugues added new dignity and attractions to the organ; they were ſoon imitated all over Europe, and wherever there was an organ and an organiſt poſſeſſed of hand and head capable of emulating a ſtyle ſo ſuitable to the genius of that inſtrument. It is not ſaid in the title page for what inſtruments the ſeveral parts were deſigned; but as the author was a great organ player, we make no doubt but that they were firſt produced by and for that inſtrument, as all the four parts are ſo compact and cloſely connected, that they are ſtill within the graſp of the two hands. Notwithſtanding many of theſe fugues are upon two, three, and even four ſubjects, and every learned artifice of inverſion, augmentation, diminution, and moto contrario, is uſed, he has had the dexterity to avoid confuſion. But as he is ſaid to have produced many motets and maſſes for the church, the ſimplicity of the ſubjects of the fugues of his ricercari and canzoni were probably thoſe of his vocal fugues. The "Sonate d'intavolatura di cimbalo ed organo partite di diverſe arie e corrente, Ballati, Ciaccone, Paſſacagli di Freſcobaldi," publiſhed at Rome in 1637, upon ſix lines for the right hand, and eight for the left, are very full, and of difficult execution. Theſe pieces being embelliſhed with the faſhionable diviſions and graces of the times, have ſuffered more by age than the ricercari, which have all the ſimplicity of vocal fugues in the church ſtyle. But even in his toccate and variations on old airs, we find more taſte and paſſages which have ſtood their ground, than in any other harpſichord muſic of the ſame period.

Our

Our Bird, Dr. Bull, and Giles Fornaby ſeem to have been the greateſt organ players in Europe during the ſixteenth century, and the beginning of the next, till Freſcobaldi introduced a ſuperior ſtyle of treating the organ, diveſted of rapid and frivolous diviſions which diſgrace that moſt noble and comprehenſive of all inſtruments. Indeed the fugues in the ricercari of Freſcobaldi are worked with ſuch genius and learning as have never been ſurpaſſed, unleſs by thoſe of Sebaſtian Bach, and Handel, which ſeem to include every perfection of which this ingenious and elaborate ſpecies of compoſition is capable. Indeed, if we except theſe fugues, all inſtrumental muſic, particularly that for keyed inſtruments, ſeems to have been in a very rude ſtate at this time throughout Europe. It was dry, difficult, unaccented and inſipid.

FRESH denotes the riſe of water in a river, or a ſmall flood. See FRESHES.

FRESH-*doors*, a ſort of ſluices to let go water, ſo that it may run in freſhes, or in ſluſhes.

FRESH *Diſſeiſin*, in *Law*, (*friſca diſſeiſina*, from the French *frais*, i. e. *recens & diſſeiſir*, viz. *poſſeſſione ejicere*,) ſignifies that diſſeiſin which a man might formerly ſeek to defeat of himſelf and by his own power, without reſorting to the king or the law; as where it was not above fifteen days old, or ſome other ſhort continuance. Britton cap. 5. Of this Bracton writes at large, concluding it to be arbitrary. Lib. iv. cap. 5. See DISSEISIN.

FRESH *Fine*, is that which was levied within a year paſt. Weſtm. 2. 13 Ed. I. ſt. 2. cap. 45. See FINE.

FRESH *Force*, *friſca fortia*, denotes a force done within forty days.

If a man be diſſeiſed of lands or tenements within any city or borough; or deforced from them after the death of his anceſtors, to whom he is heir; or after the death of his tenant for life, or in tail, in dower, &c. he may, within forty days after his title accrued, have his remedy by an aſſize, or bill of freſh force. This aſſize or bill is ſued out without any writ from the chancery; but after the forty days, there is to be a writ out of chancery, directed to the mayor, &c. But this writ is obſolete ſince ejectments have come in uſe for recovering the poſſeſſion of lands, &c.

FRESH *the Hawſe*, on board a *Ship*. See HAWSE.

FRESH *Shot*, in the *Sea-phraſe*, ſignifies the falling down of any great river into the ſea; by means whereof the ſea hath freſh water a good way from the mouth of the river. As this is more or leſs, they call it a great, or ſmall freſh ſhot.

FRESH *Spell*, in the *Sea Language*, a freſh gang, to relieve the rowers in the long boat.

FRESH *Suit*, *recens inſecutio*, in *Law*, is ſuch a preſent and active proſecution of an offender, where a robbery is committed, as never ceaſes from the time of the offence committed, or diſcovered, till he be apprehended.

The benefit of ſuch purſuit of a felon is, that the party purſuing ſhall have his goods reſtored to him; whereas otherwiſe they are forfeited to the king. When an offender is thus apprehended and indicted, upon which he is convicted, the party robbed ſhall have reſtitution of his goods; and though the party robbed doth not apprehend the thief immediately, but ſome time after the robbery, provided he uſed his utmoſt endeavours to take him; or though he happens to be apprehended by ſome other perſon, yet it ſhall be adjudged freſh purſuit. Terms de Ley. See WAIFS.

Where a gaoler immediately purſues a felon, or other priſoner eſcaping from priſon, it is "freſh ſuit," to excuſe the gaoler; and if a lord follow his diſtreſs into another's ground, on its being driven off the premiſes, this is called "freſh ſuit:" ſo where a tenant purſues his cattle that eſcape or ſtray into another man's lands, &c.

Freſh ſuit is either within the view, or without. Manwood ſays, that upon freſh ſuit within the view, treſpaſſers in the foreſt may be attached by the officers purſuing them, though without the limits of the foreſt.

It has been ſaid that freſh ſuit may continue for ſeven years. See HUE *and Cry*.

FRESH *Water*, is that not tinctured or impregnated with ſalt, or ſaline particles, enough to be diſcoverable by the ſenſe.

Such generally is that of ſprings, rains, wells, lakes, &c. Dr. Liſter is of opinion, that the natural and original ſtate of water is to be ſalt: the freſhneſs he ſuppoſes to be accidental, and to be owing to the vapours of plants, and the breath of animals therein; and to the exhalations raiſed by the ſun.

Others will have all water originally freſh, and take its ſaltneſs to be accidental; to account for which, a great number of hypotheſes have been framed.

The ſaltneſs of water is a foreign, and in moſt caſes a hurtful quality. It renders it not only nauſeous to the taſte, but greatly prejudicial to the body; and it is generally agreed that thoſe waters, *cæteris paribus*, are beſt, not only for drinking, but alſo for economical uſes, as waſhing, boiling, and brewing, which are the freeſt from ſaltneſs.

Hence, various methods have been contrived for examining the freſhneſs of waters, and for dulcifying or making ſalt water freſh.

Mr. Boyle gives us a method of examining the freſhneſs of water, by means of a precipitate, which caſts down any ſaline particles before floating therein.

Into one thouſand grains of diſtilled water he puts one grain of ſalt; and into the ſolution lets fall a few drops of a ſtrong well filtrated ſolution of a well refined ſilver, diſſolved in clear aquafortis; upon which there immediately appears a whitiſh cloud, which, though but ſlowly, deſcends to the bottom, and there ſettles in a white precipitate, in which is the ſaline matter of the fluid.

This method, if it were required, would examine water to a greater nicety than that here ſpecified. It has diſcovered ſalt in water where there was but one grain of ſalt in two thouſand, nay in three thouſand times the weight of water.

The experiment was tried before the Royal Society in 1692, by ſir Hans Sloane; where it was likewiſe found that a drop or two, even of ſpirit of ſalt, mixed with common water, would be diſcovered by the ſame method. Phil. Tranſ. Abr. vol. ii. p. 298.

Dr. Hook, in the ſame year, read a lecture before the Royal Society, on a method of his own, for diſcovering the ſmalleſt quantity of ſalt contained in water, on a principle of hydroſtatics. The operation was performed by means of a large poiſe of glaſs, of the ſhape of a bolt-head; the ball thereof was three inches in diameter, and the neck $\frac{1}{24}$th of an inch. This being ſo poiſed, with red lead put in it, as to make it very little heavier than freſh water; and then ſuſpended by the ſmall ſtem which was graduated, to the end of a nice beam of a balance; and the degree or diviſion of the neck, contiguous to the ſurface of the water, noted; upon infuſing a quantity of ſalt, only equal to the two thouſandth part of the weight of the waters, the neck of the poiſe ſunk near half an inch

inch lower in the water. Phil. Tranſ. Abr. vol. ii. p. 304.

The dulcifying, or making of ſalt water freſh, is a ſecret that has been long ſought with great attention. For an account of the principal attempts that have been made with this view, ſee *Sea*-WATER.

FRESH *Wind*, ſignifies ſtrong, but not violent; hence when the gale increaſes, it is ſaid to freſhen.

FRESHES, in *Sea-language*, denote the impetuoſity of an ebb-tide, increaſed by heavy rains, and flowing out into the ſea, often diſcolouring it to a conſiderable diſtance, and forming a line that ſeparates the two colours, and which may be diſtinctly perceived for a great length along the coaſt.

FRESHFORD, in *Geography*, a ſmall poſt-town of the county of Kilkenny, Ireland, which is 7 miles from Kilkenny on the road to Urlingford, and 64½ miles S.W. from Dublin.

FRESHWATER BAY, a bay in the ſtraits of Magellan. N. lat. 53° 27'. W. long. 72° 13'.—Alſo, a bay on the S.W. coaſt of the Iſle of Wight. N. lat. 50° 37'. W. long. 1° 31'.—Alſo, a bay on the E. coaſt of Newfoundland. N. lat. 49° 10'. W. long. 53° 30'.

FRESHWATER *Iſland*, a ſmall iſland in the Atlantic, near the coaſt of South Carolina. N. lat. 33° 5'. W. long. 79° 15'.

FRESHWATER *Key*, a ſmall iſland in the Spaniſh Main, near the Moſquito ſhore. N. lat. 14° 23'. W. long. 82° 25'.

FRESNAY, a town of France, in the department of the Sarthe, and chief place of a canton in the diſtrict of Mamers; 18 miles N. of Le Mans. The place contains 1921, and the canton 13,810 inhabitants, on a territory of 207½ kiliometres, in 12 communes. N. lat. 48° 17'. E. long. 0° 6'.

FRESNAYE, LA, a town of France, in the department of the Sarthe, and chief place of a canton in the diſtrict of Mamers, 6 miles E. of Alençon. The place contains 1,555, and the canton 6,875 inhabitants, on a territory of 145 kiliometres, in 14 communes.

FRESNE-EN-WŒVRE, a town of France, in the department of the Meuſe, and chief place of a canton in the diſtrict of Verdun, 10 miles S.E. of Verdun. The place contains 823, and the canton 12,715 inhabitants, on a territory of 257½ kiliometres, in 38 communes.

FRESNE-ET SAINT-MAMEZ, a town of France, in the department of the Upper Saône, and chief place of a canton in the diſtrict of Gray, 12 miles N.E. of Gray. The place contains 558, and the canton 9,311 inhabitants, on a territory of 200 kiliometres, in 23 communes.

FRESNEDA, LA, a town of Spain, in the province of Arragon, once ſtrongly fortified, but burned and diſmantled in the year 1706 by the troops of Philip V.; 12 miles S.S.E. of Alcaniz.

FRESNILLO, a town of Mexico, in the province of Zacatcras; 40 miles N. of Zacatcras.

FRESNO, a town of Spain, in Old Caſtile; 5 miles S. of Borgo d'Oſma.—Alſo, a town of Spain, in Andaluſia, 20 miles N. of Cordova.

FRESNOY, CHARLES ALPHONSE DU, in *Biography*, a poet and a painter, deſervedly regarded with more eſtimation in the former than the latter character; although painting was the object of his moſt anxious deſires and labours, and poetry but the amuſement of his leiſure hours.

He was born in Paris in the year 1611, and deſtined by his father, who was an apothecary, to the profeſſion of phyſic. He therefore received a good education, and early in life evinced a taſte for poetry, and carried away all the prizes in it which were propoſed in the college where he was educated, to excite the emulation of his fellow ſtudents. His inclination for it increaſed with exerciſe, and the pleaſure he took in that, and its ſiſter art of painting, which poſſeſſed equal power over him, diverted him ſo much from the ſtudies requiſite for the practice of the profeſſion he was intended for, that he at laſt, notwithſtanding the oppoſition and remonſtrances of his parents, gave over the purſuit of it, declaring himſelf decidedly for painting; which he took every opportunity of cultivating with great aſſiduity.

At the age of nineteen or twenty he began to learn deſign under F. Perier; after two years ſpent with that artiſt and Simon Vouet, he went to Italy in the year 1633, or beginning of 1634.

At firſt he employed himſelf in painting landſcapes, buildings, and ancient ruins; with great reſolution perſevering in his deſire to be a painter, although abandoned by his parents through reſentment for his rejection of a profeſſion they had choſen for him. In Rome he was deſtitute of friends and acquaintance for the firſt two years of his reſidence there, and for the greateſt part of that time he ſubſiſted on bread and cheeſe, diverting uneaſy reflections by an indefatigable purſuit of painting.

The arrival of Peter Mignard, afterwards ſo celebrated, who had been his friend and fellow ſtudent under Vouet, ſet him more at eaſe. They united in the ſtricteſt ties of friendſhip, lived together in the ſame houſe, and were commonly known in Rome by the name of the *Inſeparables*.

They principally ſtudied the works of Raphael, and the antiques: but other artiſts of great celebrity had alſo a ſhare of their attention, particularly Titian and Carracci: the former of whom Du Freſnoy had great eſteem for, and copied ſeveral of his works; endeavouring to imitate him in his colouring, as he did Carracci in his deſign. In the progreſs of their ſtudies, Mignard appeared to poſſeſs ſuperior talents in practice, while Freſnoy, who was perhaps more of a reaſoner, entered more into the rules, the theory, and hiſtory of the art. Each communicated to the other his ſentiments and obſervations; Du Freſnoy furniſhing his friend with noble and excellent ideas, and receiving in return advice and inſtructions in the beſt mode to realize his inventions with expedition and effect.

Whilſt he lived in Rome, he painted ſeveral pictures of the ruins of the Campo Vaccino. One of a young Athenian woman going to ſee the monument of her lover. Æneas carrying his father, &c. &c. But poetry ſhared with painting his time and thoughts too much to allow him ever to make a ſhining figure in the practice of the latter profeſſion. As he, by a ſtudious examination of good works, penetrated into the ſecrets of the art, he wrote down his obſervations; and having ſatisfied himſelf with the knowledge he had acquired of its theory, he formed the deſign of writing a poem upon it, which he employed many years upon, conſulting the beſt writers, and examining the beſt pictures, to perfect his information, and render his labours truly uſeful.

About the year 1653 he travelled in company with Mignard (according to Felibien) through Lombardy to Venice, and there painted ſome pictures, imitating the ſtyle and colour of Titian with conſiderable ſucceſs. Here the two friends ſeparated, Mignard returning to Rome, and Du Freſnoy to France. He read his poem to the beſt painters in all places through which he paſſed, and particularly to Albano, and Guercino, then at Bologna; and he conſulted ſeveral men famed for their ſkill in polite literature.

Returned to Paris in 1656, he met with conſiderable ſuc-

cefs in painting; it being then the faſhion to paint the walls and cielings of rooms, he was much engaged in that degrading application of the art. He painted both figures and landſcapes, and ſometimes alſo gave deſigns for architecture. But his works in both theſe arts are diſregarded when compared with the excellencies of other artiſts. His reputation for genius and talent reſts upon his poem, which, after many years of reviſion and correction, he proceeded to prepare for publication.

Though he had finiſhed this didactic labour before he left Italy, and communicated it to the beſt judges of that country; yet after his return to France, he continued to revife it, with a view to treat more at length ſome things which did not ſeem to him ſufficiently explained. And though he was deſirous to ſee his work in print, yet having written it in Latin, he thought it improper to publiſh it without a French tranſlation, which he deferred undertaking from time to time, out of diffidence of his ſkill in his own native language, which he had in ſome meaſure loſt by his long reſidence in Italy. Monſ. du Piles was therefore at laſt induced, at his deſire, and by the merit of the poem, to tranſlate it into French: his verſion being reviſed by Du Freſnoy himſelf, who had begun a commentary upon it, when he was ſeized with a palſy, and after languiſhing four or five months under it, he died at the houſe of one of his brothers at Villiers-le-bel, four leagues from Paris, in 1665, at the age of 54, and was interred in the pariſh church. He had quitted his lodgings at Monſ. Potel's, in the ſtreet Beautreilly, on Mignard's return from Italy in 1658, and the two friends lived together from that time till the death of Du Freſnoy.

His poem was not publiſhed till three years after his death; when it was printed in Paris, in duodecimo, with the French verſion, and remarks of Monſ. Du Piles, and has been juſtly admired for its elegance, perſpicuity, and the utility of the inſtruction it contains. In 1694, Dryden was induced to make a proſe tranſlation of it into Engliſh, which he accompanied with his ingenious parallel between poetry and painting. It was again tranſlated into Engliſh by Mr. Wills, a painter, who gave it in metre without rhyme. He attempted to produce the ſenſe of his author in an equal number of lines, and thus cramped his own ſkill; and produced a work unequal in itſelf, in which, however well he appears to have underſtood the original text, he fails to impreſs it on his reader. It is now almoſt totally forgotten.

More ample juſtice has been done in our language to the talents of Du Freſnoy, by our late ſkilful poet William Maſon, M. A.; by whom, in 1782, he was firſt clothed in an Engliſh dreſs ſuited to his elevated pretenſions. And ſtill greater honour was done to him by the hand of that extraordinary genius of our iſle in the art of painting, ſir Joſhua Reynolds, for whoſe more valuable remarks upon the moſt important points in the poem, Mr. Maſon was induced to diſcard thoſe of Monſ. Du Piles. This tranſlation is written in heroic verſe, and is accompanied by fifty-nine notes from the pen of ſir Joſhua Reynolds.

By the union of the talents of two men ſo renowned in the arts of poetry and painting, Du Freſnoy is rendered for ever dear to the Engliſh reader; and the thorough knowledge he has exhibited of the beſt principles of the art of painting, become more agreeably and more extenſively diffuſed. See Life of Du Freſnoy by Wills and Maſon.

FRESTA, in *Geography*, a town of Sweden, in the province of Upland; 21 miles S.E. of Upſal.

FRET, in *Architecture*, a Grecian decoration, conſiſting of ſtraight grooves or fillets, running at right angles in the manner of a ſpiral, or turning round in various directions, repeating the ſame turns or forms in compartments, or at various intervals. The fret is one of the moſt ancient ornaments, (ſee Stewart's Antiquities of Athens,) in which a great variety of the moſt beautiful will be ſeen in various parts of that work.

The appellation is ſaid to have been derived from this circumſtance, that the French word *frette* literally ſignified the timber-work of a roof, which conſiſts chiefly of beams, rafters, &c. laid acroſs each other, and, as it were, fretted.

FRET, or *Frette*, in *Heraldry*, is a bearing conſiſting of ſix bars, croſſed, and interlaced, fret-wiſe.

Guillim derives the word from the French *rets*, net: but the reader will eaſily furniſh himſelf with a better etymology from the word fret, in architecture.

He bears diamond, a fret topaz; the coat armour formerly of the lord Maltravers, and now quartered by the duke of Norfolk. When it conſiſts of more than ſix pieces, the number muſt be ſpecified.

Some call this the "true lover's knot;" others "Harrington's knot," becauſe it is their arms; and "nodo firmo," the motto. Gibbon is for calling it "heraldorum nodus amatorius."

FRET, in *Muſic*, is a ſtring tied round the neck of ſome inſtrument, ſuch as the viol de gamba, and lute, to aſcertain the preciſe part of the finger-board, where the fingers of the left hand are to be placed.

FRET-*work*, an enrichment of frets, or a place adorned with ſomething in the manner thereof. See FRET.

Fret-work is ſometimes uſed among us to fill up and enrich flat, empty ſpaces; but it is principally practiſed in roofs, which are fretted over with plaſter-work.

The Italians alſo apply it to the mantlings of chimneys with great figures: a cheap piece of magnificence, and as durable almoſt within doors, as harder matters in the weather.

*FRETTS, in *Mineralogy*, a term uſed by our miners to expreſs the worn ſide of the banks of the rivers in mine-countries, where they ſearch for the ſhoad ſtones, or grewts, waſhed down from the hills, in order from thence to trace out the running of the ſhoad up to the mine. Phil. Tranſ. N° 69.

FRETTY, or FRETTE, in *Heraldry*, is where there are divers bars laid acroſs each other.

Fretty is of ſix, eight, or more pieces. Azure, fretty of eight pieces, or, the coat of the lord Willoughby.

Columbiere obſerves, that fretty, abſolutely uſed, without any addition, is ſuppoſed to be of ſix pieces; that is, ſo many bars or pieces croſſing each other, which, therefore, need not be expreſſed; but if there be more, as much muſt be mentioned. And yet Guillim has azure, fretty of ſix, argent; the coat of the ancient lords Elthingham, of Suſſex.

FRETUM, STREIGHT, or *Straight*, in *Geography*. See STRAIGHT.

FRETUM *Britannicum*, or *Gallicum*, in *Ancient Geography*, denotes the ſtreights between Dover and Calais.

FRETUM *Gaditanum*, the *Straights of Gibraltar*, denotes the ſtreights between Spain and Africa, connecting the Mediterranean ſea with the ocean; called alſo *Fretum Herculaneum*.

FRETZENDORF, in *Geography*, a town of Germany, in the biſhopric of Bamberg; ſeven miles N.W. of Burg Eberach.

FREUDAH, a town of Algiers; 10 miles S. of Maſcar.

FREUDENBERG, a town of Pruſſia, in Natangen.—Alſo, a town of Germany, in the principality of Naſſau-Siegen.—Alſo, a town of Bavaria.—Alſo, a town of Ger-

many, in the county of Wertheim on the Mayn.—Alſo, a town of Pruſſia, in Ermeland.

FREUDENSTADT, a town of Wurtemburg, founded in 1600, as an aſylum for the Proteſtants who were perſecuted in Germany; ſituated in the Black foreſt, fortified in the modern manner, and defended by a citadel. In 1796 it was taken by the French; 24 miles E.S.E. of Straſburg. N. lat. 48 28′. E. long. 8° 25′.

FREUDENTHAL, or BRUNTHAL, a town and lordſhip of Sileſia, in the principality of Troppau; celebrated for its breed of horſes and manufacture of fine linen; 17 miles W. of Troppau. N. lat. 49° 50′. E. long. 17° 21′.

FREUDENTHAL, a town of Germany, in the principality of Wurzburg; five miles W.N.W. of Volckack.

FREVENSTEIN, a town of the duchy of Stiria.

FREVENT, a town of France, in the department of the ſtraits of Calais; ſix miles W. of Arras.

FREVILLE, a town of France, in the department of the Lower Seine; five miles N.E. of Caudebec.

FREUNDSHEIM, a town of Germany, in the Tyrol; 24 miles W. of Inſpruck.

FREUSBURG, a town of Germany, in the county of Sayn; ſeven miles S.E. of Siegen.

FREYBERG, or PRZIBOR, a town of Moravia, in the circle of Prerau; 36 miles E. of Olmutz. N. lat. 49° 34′. E. long. 18° 15′.

FREYBERG, or *Friedberg*, a town of Germany, and capital of the circle of Erzgeburg, ſeated on a branch of the Moldaw, near mountains which ſeparate the country from Bohemia. It contains ſix churches, 2000 houſes, and 60,000 inhabitants. In its environs are mines of copper, tin, lead, and ſilver, which produce about 10,000 rix-dollars annually. The adjacent ſoil, though mountainous, is fertile; 19 miles W.S.W. of Dreſden. N. lat. 50° 53′. E. long. 13° 18′.

FREYBERG, mountains of Switzerland, in the canton of Glarus, which divide the valley, forming a principal part of this canton, about a league S. of the burgh of Glarus, at the point where the two rivers, Linth and Sernft, unite.

FREYBERG, or *Freyburg*, a town of Sileſia, in the principality of Schweidnitz, near the river Polonitz; ſeven miles W. of Schweidnitz. N. lat. 50° 42′. E. long. 16° 16′.

FREYBURG, a town of Germany, in Thuringia, on the Unſtrutt; 16 miles S. of Halle. N. lat. 51° 14′. E. long. 11° 54′.

FREYDENBACH, a town of Germany, in the principality of Anſpach.

FREYE-AEMTER, a country of Switzerland, encompaſſed by the cantons of Zurich, Berne, Lucerne, and Zug, and the county of Baden; anciently called the "county of Rori, or Waggenthal;" belonging to the counts of Hapſburg, and gained in conqueſt by the Swiſs in the year 1415. The inhabitants, amounting in number to about 20,000, are Roman Catholics, and they are chiefly employed in the cultivation of their fields and vineyards. The country is about ſeven or eight leagues in length, and three or four in breadth.

FREYEN, a ſmall iſland in the North ſea, near the coaſt of Norway. N. lat. 63° 42′.

FREYENSEEN, a town of Germany, in the principality of Solms; formerly an imperial town.

FREYENSTADT, a town of Germany, in the lordſhip of Breiteneck, ſituated on the Schwarzach; 20 miles S.E. of Nuremberg. N. lat. 49° 9′. E. long 11° 15′.

FREYENTHURN, a town of Middle Carniola, on the Kulp; ſeven miles E. of Rudolfswerth.

FREYENWALDE, a town of Germany, in the Middle Mark of Brandenburg, on the Oder. The trade of the inhabitants, which is conſiderable, is carried on in fiſh, corn, lace, linen, medicinal waters, and alum; 32 miles N.E. of Berlin. N. lat. 52° 51′. E. long. 14° 5′.

FREYHAN, a town and lordſhip of Sileſia, in the principality of Oels, on the borders of Pruſſia; 24 miles N. of Oels. N. lat. 38° 12′. E. long. 17° 20′.

FREYHEIL, a town of Bohemia, in the circle of Konigingratz, near which are warm baths.

FREYHOFF, a town of Carniola, on the Kulp; ſeven miles S.W. of Landſtrap.

FREYHUNG, a town of Germany, in the principality of Sulzbach; 10 miles N.E. of Sulzbach.

FREYLA, a town of Spain, in the country of Grenada; 18 miles N.N.E. of Guadix.

FREYLING, a town of Auſtria; four miles E.S.E. of Efferding.

FREYSINGEN, or FRISINGEN, *Biſhopric of*, an eccleſiaſtical principality of Germany, in the circle of Bavaria, ſituated between the cities of Munich and Landſhut, founded by St. Corbinien, who was created biſhop by pope Conſtantius III. about the year 710. It includes within its territories the town of Freyſingen, the county of Iſmaning, the lordſhip of Burgkrain, and the county of Werdenfeils. In 1801 this biſhopric was ſecularized, and granted to the elector (now king) of Bavaria. The town of Freyſingen is ſituated on the Moſach, not far from the Iſer, partly at the foot of a mountain, and partly on its ſummit. The epiſcopal palace and cathedral church, which are beautiful edifices, are ſituated in the upper part of the town; taken by the French in 1796; 17 miles N.N.E. of Munich. N. lat. 48° 20′. E. long. 11° 44′.

FREYSTADT, a town of Pruſſia, in the province of Oberland; 80 miles S.W. of Konigſberg.—Alſo, a town of Sileſia, in the principality of Glogau, containing a Roman catholic church, a convent, and a Lutheran church and ſchool. Good cloth is manufactured in this town; 12 miles N.E. of Sagan. N. lat. 51° 44′. E. long. 15° 25′.

FREYSTADTEL, a town of Sileſia, in the principality of Teſchen; ſeven miles W.N.W. of Teſchen. N. lat. 49° 49′. E. long. 18° 34′.

FREYSTATT, or FREUSTADT, a town of Auſtria; 82 miles W. of Vienna. N. lat. 48° 30′. E. long. 14° 25′.

FREYSTATTEL, a town of Moravia, in the circle of Hradiſch; 20 miles N.E. of Hradiſch.

FREYSTATTL, a caſtellated town of Hungary, on the Waag.

FREYSTETT, or FREYSTAETT, a town of Germany, in the county of Catzenelnbogen, on the Mayn; where Roman Catholics, Lutherans, and Calviniſts, are allowed the free exerciſe of their religion; 12 miles N.W. of Darmſtadt.

FREYUNG, a town of the biſhopric of Paſſau; 14 miles N. of Paſſau.

FREYWALDE, a town of Sileſia, in the principality of Neiſſe; 15 miles S. of Neiſſe. N. lat. 50° 5′. E. long. 17° 5′.—Alſo, a town of Sileſia, in the principality of Sagan; 12 miles S.W. of Sagan.

FREZIER, AMEDEE-FRANCIS, in *Biography*, was born at Chamberry in 1682, and was intended by his parents for the profeſſion of the law, but his own inclination led him to devote the ſtrength of his talents to mathematics. He ſoon qualified himſelf for the engineer ſervice of his country, and was employed, in 1711, by the court, in a ſurvey of the Spaniſh colonies of Peru and Chili; and on his return from thoſe countries he publiſhed a "Voyage to the South Sea," which obtained him a high degree of credit. After this

this he was entrusted with the superintendence of several important fortifications, and for the great ability exhibited on this, and other occasions, in the service of government, he was rewarded with the cross of St. Lewis, and made lieutenant-colonel in the army. In 1740 he was appointed director of all the fortified places in Britanny. He died at Brest in the year 1773. He was author of "Traité des Feux d'Artifice." "Elemens de Stereotomie," in two volumes 8vo. This last was enlarged under the title of "Theorie et Pratique de la Coupe des Pierres et des Bois," in three volumes 4to. He is highly esteemed as an author, particularly for his last work.

FREZIERA, in *Botany*, in memory of Amadeus Francis Frezier, an engineer in the service of Louis XIV., who published a Voyage to Chili and Peru, and died in 1773, at the age of 91. He made some botanical observations, and introduced the Chili Strawberry into Europe; see FRAGARIA CHILOENSIS. He was greatly at variance with Father Feuillée, who attacked him in the preface of his own Voyage, and was answered by Frezier in a subsequent edition of his publication; see FEUILLÉE.—Swartz. Ind. Occ. v. 2. 971. Willd. Sp. Pl. v. 1179. (Eroteum; Swartz. Prod. 85. Schreb. 807. See EROTEUM.)—Class and order, *Polyandria Monogynia*. Nat. Ord. *Aurantia*, Juss.

Gen. Char. *Cal.* Perianth of five ovate, concave, incumbent, permanent leaves. *Cor.* Petals five, roundish, inclining to ovate, concave, undivided, spreading. *Stam.* Filaments numerous (30), inserted into the receptacle, shorter than the petals, erect, thread-shaped; anthers roundish, minute. *Pist.* Germen superior, ovate, downy; style solitary, erect, rather longer than the stamens, awl-shaped, three or five-cleft at the summit, permanent; stigmas blunt, simple, reflexed. *Peric.* Berry roundish, dry, smooth, pointed with the permanent style, of three to five cells. *Seeds* three or four in each cell, oblong, slightly compressed.

Ess. Ch. Calyx of five leaves. Petals five. Style three to five-cleft. Berry dry, of three to five cells, with many seeds.

Obs. The inflorescence, flower and habit are those of *Thea*, but the fruit is different. *Swartz.*

1. F. *theoides*. Sw. Ind. Occ. v. 2. 972.—"Leaves lanceolate, somewhat ovate, bluntly serrated, smooth. Flowers axillary, solitary."—Native of lofty mountains in the southern part of Jamaica. A *tree* from 20 to 40 feet high, with a smooth greyish bark, and upright sub-divided branches. *Leaves* alternate, stalked, pointed, ribbed, smooth, shining on the upper side, rather rigid. *Flowers* few, stalked, drooping, whitish, resembling those of the tea shrub, but only half their size. They appear in June and July, and the berries ripen in October. The leaves are said by Swartz to be astringent, and to have precisely the taste of green tea. They might perhaps prove a better substitute for the Chinese plant than the leaves of ash, sloe, or whatever else serves to adulterate that valuable article of commerce in Europe.

2. F. *undulata*. Sw. Ind. Occ. v. 2. 974. (Eroteum undulatum; Vahl. Symb. v. 2. 61.)—"Leaves elliptic-lanceolate, pointed, serrated, smooth. Flowers axillary, clustered."—Native of woods on the highest mountains of the West Indies. An elegant *tree*, often rising to the height of 50 feet, the *branches* nearly erect, brown, with elevated white spots. *Leaves* about four inches long, serrated and undulated, finely veined, smooth, palest beneath; their stalks about an inch long, reddish, channelled above, smooth. *Flower-stalks* somewhat umbellate, rarely solitary. *Flowers* whitish. *Swartz.*

3. F. *reticulata*. Humboldt and Bonpland Plant. Æquinoct. v. 1. 22. t. 5.—"Leaves ovato-lanceolate, serrated, downy and reticulated beneath. Flowers axillary, two or three together, stalked."—Native of Peru, on the Andes, near the town of Almagner. *Stem* about 18 feet high, bearing many downy, reddish, leafy, warty *branches*. *Leaves* about three inches long, serrated; smooth above; finely downy and reticulated beneath. *Footstalks* an inch or more in length, downy. *Flower-stalks* two or three together, downy, as well as the *calyx*. *Petals* white, scarcely longer than the calyx. *Fruit* of four cells.

4. F. *hirsuta*. Leaves elliptic-lanceolate, bluntly serrated, smoothish with a hairy rib; unequal at their base. Flowers axillary, two or three together, stalked. Branches hairy.—Native of high cool mountains, where the atmosphere is always damp, in the island of St. Vincent, from whence it was sent by Dr. Alexander Anderson to A.B. Lambert, esq. from whose rich herbarium we have been favoured with a specimen. It seems very nearly akin to the last, but the young *branches* are extremely hairy, the *leaves* smaller, scarcely rough beneath except the rib, and remarkably unequal at their base. The *flowers* moreover are scarcely half so large as in F. *reticulata*, with very hairy stalks and calyx.

5. F. *canescens*. Humb. and Bonpl. Pl. Æquinoct. v. 1. 25. t. 6.—Leaves elliptical, tapering at each end, minutely serrated, hoary beneath. Flowers solitary or in pairs, stalked.—Native of the Andes of Peru, between the towns of Quito and Ybarra. A *tree* 18 feet high. *Branches* spreading, smooth, except at their extremities, where they are finely downy. *Leaves* three or four inches long, somewhat revolute, very finely serrated, hoary and downy at the back. *Flowers* rather large, mostly solitary, white, with downy stalks and calyx. *Petals* externally downy, twice as long as the calyx. *Fruit* of three cells.

6. F. *chrysophylla*. Humb. and Bonpl. Pl. Æquinoct. v. 1. 27. t. 7.—Leaves elliptic-lanceolate, pointed, entire; downy beneath. Flowers two or three together, stalked.—Native of cold parts of the Andes of Peru, near the town of Popayan. Remarkable for its entire *leaves*, which are smooth above, and of a fine golden hue at the back, with an appearance of two parallel lines on each side of the rib, but this is only caused by the arrangement of the hairs. *Petals* whitish, pointed, more than twice as long as the calyx.

7. F. *fericea*. Humb. and Bonpl. Pl. Æquinoct. v. 1. 29. t. 8.—Leaves ovate, pointed, finely serrated, silvery beneath, on short stalks. Flowers sessile.—Very frequent in cold parts of the province of Pasto in Peru, between the towns of Quito and Popayan. A *tree* 30 feet high, with angular smooth *branches*. *Leaves* nearly sessile, four inches long, broad at the base, smooth above, clothed beneath with white silky hairs, slightly veined. *Flowers* two or three together, sessile, small. *Calyx* smooth. *Petals* twice as long as the calyx, white, obtuse. *Berry* of from three to five cells.

8. F. *nervosa*. Humb. and Bonpl. Pl. Æquinoct. v. 1. 31. t. 9.—Leaves elliptic-ovate, pointed, serrated; veiny and somewhat hairy beneath. Flowers many together, stalked.—Native of cold situations in the province of Pasto in Peru. A *tree* above thirty feet high, with nearly smooth *branches*. *Leaves* marked with numerous transverse veins, and slightly hairy, beneath. *Flowers* small, white. The wood is valuable, and much used in building.

FRIABLE SOIL, in *Agriculture*, is such as has the particles readily broken down, and reduced into a powdery state. See SOIL.

FRIANGOMBI, in *Geography*, a town of Africa, in Congo, on the Zaine, near Lembo.

FRIAR, or FRIER, by the Latins called *frater*, the Italians *fra*, and the French *frere*, that is, *brother*, is a term common to the monks of all orders; founded on this, that there is a kind of fraternity, or brotherhood, preſumed between the ſeveral religious perſons of the ſame convent or monaſtery.

The kinds of friars are very numerous: Auguſtine friars; Dominican, or black, or preaching friars; Franciſcan, or grey, or begging friars; and Carmelites, or white friars.

FRIAR, in a more peculiar ſenſe, is reſtrained to ſuch monks as are not prieſts; for thoſe in orders are uſually digniſied with the appellation of *father*.

FRIARS, or FRIERS, *obſervant*, *fratres obſervantes*, were a branch of the Franciſcans; thus called, becauſe not combined together in any cloyſter, convent, or corporation, as the conventuals are, but only agreed among themſelves to obſerve the rules of their order, and that more ſtrictly than the conventuals did, from whom they ſeparated themſelves out of a ſingularity of zeal, living in certain places of their own chuſing.

FRIAR'S *Cowl*, in *Botany*. See ARUM.

FRIAR'S *Head*, in *Geography*, a cape on the E. coaſt of Antigua. N. lat. 17° 11'. W. long. 61° 22'.

FRIAR'S *Hood*, a mountain of Ceylon, near the coaſt; 68 miles E. of Candy.

FRIARY *of the Holy Trinity*. See TRINITY.

FRIAS, in *Geography*, a town of Spain, in Old Caſtile, ſituated on an eminence, near the Ebro; 20 miles N. N. E. of Burgos. N. lat. 42° 40'. W. long. 3° 2'.

FRIBURGH, FRIDBURGH, or *Fritheborg*, among our Anglo-Saxon anceſtors, denoted the ſame as frank-pledge did after the time of the conqueſt.

"Præterea eſt quædam ſumma et maxima ſecuritas, per quam omnes ſtatu firmiſſimo ſuſtinentur, *viz.* ut unuſquiſque ſtabilitat ſe ſub fidejuſſionis ſecuritate, quam Angli vocant *freoborghes*; ſoli tamen Eboracenſes dicunt eandem *tienmannatale*, quod ſonat Latine decem hominum numerum." LL. Edw. II. ap Lamb.

Every man in this kingdom was anciently aſſociated in ſome *decennary*, (which ſee,) or company of ten families, who were pledged, or bound for each other, to keep the peace, and obſerve the law. (See TITHING.) If any offence was done by one, the other nine were to anſwer it; that is, if the criminal fled from juſtice, they had thirty days allowed to apprehend him; if he was not taken in that time, he who was the friburgh, *i. e.* the principal pledge of the ten, ſhould take two of his own number, and the chief pledges of three neighbouring friburghs, with two others out of each of the ſaid friburghs, who were to purge themſelves, and their friburgh, of the forfeiture and flight of the criminal. If they could not do this, the principal pledge, with the other eight, were to make ſatisfaction.

Great men were not combined in any ordinary decenna, or dozen, as being deemed a ſufficient aſſurance for themſelves and their menial ſervants.

FRIBURG, or FREYBURG, in *Geography*, a town of Germany, in the circle of Swabia, and capital of the Auſtrian Briſgaw, (ceded to the duke of Modena by the treaty of Campo Formio in 1797, and that of Luneville in 1801,) ſituated at the foot of a ſtony mountain on the river Traiſam. This town was founded, in 1118, by Berchtold III. duke of Zæringen, from whom it came to the counts of Furſtenberg, with whom it had many diſputes on account of its privileges; but at laſt it purchaſed its freedom for 20,000 marks of ſilver. This ſum was advanced by the houſe of Auſtria, ſo that the town became ſubject to that family. The French took and diſmantled it in 1744. It was again taken by the French in 1796, and ſoon ſurrendered to the archduke. The ſtreets are broad and well paved; the principal church is a ſuperb edifice. Here is an univerſity, founded in 1457, by Albert IV. duke of Auſtria, with an academy, and five colleges dependent upon it; it has 10 convents, a commandery of the Teutonic order, and 13 churches. The principal buſineſs of the town is that of poliſhing cryſtals and precious ſtones; 34 miles S. S. E. of Straſburg. N. lat. 48° 2'. E. long. 7° 54'.

FRIBURG, or FREYBURG, called *Friburg* in *Uckland*, by way of diſtinction from *Friburg in the Briſgaw*, a town of Switzerland and capital of a canton, to which it gives name. This town was built, in 1179, by Berchtold IV., duke of Zæringen, and endowed by him with conſiderable privileges. In 1218, the ſovereignty of it deſcended to Ulric of Kyburgh, in right of his wife Anne, ſiſter of the laſt duke Berchtold V. By marriage it came into the poſſeſſion of Eberhard, count of Hapſburg-Lauffenburg, who ſold it to his couſin Rhodolph of Hapſburgh, afterwards emperor. During this period a continual rivalſhip ſubſiſted between Bern and Friburg; but at length all differences were compoſed, and in 1403 the two cities concluded a perpetual alliance. Friburgh continued under the dominion of Auſtria until the middle of the 15th century, when it put itſelf under the protection of the duke of Savoy. From this era it occaſionally aſſiſted the cantons againſt the houſe of Auſtria; but ſoon after the battle of Morat, in which its troops had a ſhare in the victory then obtained, it became a free and independent republic, and, in 1481, it was admitted a member of the Helvetic confederacy. The ſituation of Friburgh is one of the moſt pictureſque and wild in Switzerland; as it ſtands partly in a ſmall plain, partly on bold acclivities, on a ridge of rugged rocks, half encircled by the river Sane; and is ſo entirely concealed by the circumjacent hills, that the traveller ſcarcely catches the ſmalleſt glimpſe, until he burſts upon a view of the whole town from the overhanging eminence. The fortifications, conſiſting of high walls and towers, incloſe a circumference of about four miles; within which ſpace the eye comprehends a ſingular mixture of houſes, rocks, thickets, and meadows, varying inſtantly from wild to agreeable, from the buſtle of a town to the ſolitude of the deepeſt retirement. The Sane flows in a ſerpentine courſe, ſo as to form, within the ſpace of two miles, five angles, between which the different parts of the current are nearly parallel to each other. On all ſides the deſcent to the town is extremely ſteep, and in one place the ſtreets even paſs above the roofs of the houſes. Many of the edifices are raiſed in regular gradation like the ſeats of an amphitheatre. The moſt extraordinary point of view is from the Pont-neuf. The houſes, conſtructed with a grey ſandſtone, brought from a neighbouring quarry, are neat and well-built; but the whole town has a dull and inanimate appearance. Among the few objects worthy of particular notice are, the cathedral, an elegant Gothic edifice, erected in the latter end of the 14th century, and remarkable for the height and ſolidity of the tower. The town-houſe, an ancient building, and a lime-tree planted in the middle of the principal ſquare by a ſoldier, as tradition reports, June 22d 1477, on his return from the battle of Morat, and regarded as an emblem of Swiſs liberty. The ſociety of Friburgh is very agreeable; the gentry are frank and hoſpitable, and blend French politeneſs with great ſimplicity of manners. The biſhop of Lauſanne, called here the biſhop of Friburgh, reſides in this city. Under the old eſtabliſhment, he was appointed by the pope, uſually at the recom-

mendation of the French court; and his revenues commonly amounted to about 400*l.* per annum. His dioceſe extends over the whole canton, and part of that of Soleure. This canton is entirely Catholic, and its population, in 1785, was eſtimated at 57,589 perſons, the town containing 5,011. According to the ſtatement of Mr. Planta in his "Hiſtory of the Helvetic Confederacy," the canton of Friburgh, before the revolution, conſiſted of 467 ſquare miles, and contained 73,000 inhabitants. This canton contains a ſmall portion of arable land, but abounds in paſtures; accordingly, its principal articles of exportation conſiſt in horned cattle, cheeſe, butter, and hides. Its cheeſe is famous under the name of Gruyeres, derived from that of the diſtrict in which it is made. (See GRUYERES.) It may be eſtimated upon an average, that the whole canton annually ſupplies paſture for 37,000 cows and oxen. It the year 1798, the town ſurrendered to the French army, under the command of general Pigeon; and as ſoon as the French took poſſeſſion of it, a proviſional government, elected by the diſtricts of Friburgh, ſuperſeded the former magiſtracy, conſiſting of a council of 200. According to the conſtitution of 1801 it formed, with the addition of the bailliages of Morat and Schwartzenburgh, one of the 17 departments or cantons of Switzerland, deputing four repreſentatives to the general diet. By the conſtitution of 1803, the force which this canton is required to ſupply conſiſts of 620 men. Friburgh is diſtant 16 miles S. W. from Berne, and 27 N. E. from Lauſanne. N. lat. 46° 50′. E. long. 6° 48′.

FRIBURG, a town of Bavaria; 15 miles S. S. E. of Brannau.

FRIBUS, a town of Bohemia, in the circle of Einbogen; nine miles W. of Joachimſtel.

FRICALA, a town of European Turkey, in Theſſaly; 35 miles W. of Lariſſa.

FRICASSEE, a diſh, or meſs, haſtily dreſſed in a frying-pan, and ſeaſoned with butter, oil, or the like.

The word is French, formed of the Latin *frixatura*, frying. Others will have fricaſſee formed in imitation of the noiſe made by butter, or other fat, when melted in the pan.

We ſay a fricaſſee of pullets, or rabbits, of tench, of tripe, of frogs, of eggs, of peas, &c.

FRICCIUS, MELCHIOR, in *Biography*, a phyſician, who practiſed his profeſſion at Ulm in the latter part of the ſeventeenth century. Reſpecting the particular circumſtances of his life, little has been recorded; but he left ſeveral intereſting works on medical ſubjects, of which his treatiſe on the medicinal properties of poiſons deſerves particular mention. He was one of the firſt to demonſtrate to the profeſſion, from reaſon, experience, and authority, that poiſonous ſubſtances may be employed without danger, both internally and externally; and that, deleterious as they are in certain quantities and on certain occaſions, the prudent phyſician may derive from them the moſt efficacious remedies againſt the moſt obſtinate diſeaſes. The poiſons, which Friccius arranged in the claſs of remedies, are principally arſenic, corroſive muriate of mercury, euphorbium, aconite, cicuta, bella donna, hyoſciamus, &c. Although the fears and prejudices of his contemporaries led them to diſcredit his facts, and to look upon his reaſoning as viſionary, his poſterity have realized his ſtatements, in conſequence of the experiments of Van Swieten, Storck, Fowler, &c.; and theſe ſubſtances are now reſorted to, as ſome of the moſt active agents of the materia medica. The following are the titles of the publications of Friccius. 1. "Diſſertatio Medica de Peſte, ſeu, nova Methodus cognoſcendi et curandi Peſtem," Ulm, 1684.—2. "Icon Podagræ, repreſentans morbi podagrici hiſtoriam, cauſas, prognoſin, et curationem," Ibid. 1693.—3. "Tractatus Medicus de Virtute Venenorum Medicâ,". Ibid. 1693, 1701.—4. "De Colica ſcorbutica," Ibid. 1696.—5. "Paradoxa Medica in quibus plurima curioſa et utilia contra communes Medicorum Opiniones pertractantur," Ibid. 1699.—Eloy. Dict.

FRICENTI, in *Geography*, a town of Naples, in Principato Citra, the ſee of a biſhop, united with Avellino; 18 miles S.E. of Benevento. N. lat. 40° 59′. E. long. 15° 2′.

FRICHE, or FRISCHE, JAMES DU, in *Biography*, a learned French Benedictine monk, was born in Normandy in the year 1641. He embraced the eccleſiaſtical life, and purſued his ſtudies with ſo much diligence and ardour, that he was ſelected by his ſuperiors as a proper perſon for ſuperintending ſome of the noble editions of the fathers which they ſent into the world. He was fixed on to publiſh the works of St. Ambroſe, which appeared at Paris, in two volumes folio, in 1686, and, in 1690, enriched with notes, various readings, remarks, &c. Friche was afterwards employed to prepare for the preſs a new edition of the works of St. Gregory Nazianzen, but he died before he could complete his plan, which happened at Paris in 1693, when he was about fifty-two years of age. Friche was likewiſe author of the "Life of St. Auguſtine," prefixed to the Benedictine edition of the works of that father. He had likewiſe filled the profeſſorſhip of rhetoric at Thiron with much reputation. Moreri.

FRICIUM, of *frico*, *I rub*, in *Pharmacy*, a name given to ſuch medicines as are intended to be rubbed into the ſeveral parts of the body. The ancients had three kinds of fricia, the dry, the ſoft, and the liquid; the firſt was uſed in the way of fumigation, the ſecond was bound on the part with cloths, and the laſt was uſed by way of embrocation.

FRICKTHAL, in *Geography*, a diſtrict on the left bank of the Rhine, which the emperor of Germany agreed to cede to the French republic by the treaty of Campo Formio and that of Luneville.

FRICTION, in a general ſenſe, the act of rubbing or grating the ſurface of one body againſt that of another, called alſo *attrition*.

The phenomena ariſing upon the friction of divers bodies under different circumſtances, are very numerous and conſiderable.

Mr. Hawkſbee gives us a number of experiments of this kind; particularly of the attrition, or friction of glaſs, under various circumſtances, the reſult of which was, that it yielded light, and became electrical.

All bodies by friction are brought to conceive heat; many of them to emit light; particularly a cat's back, ſugar, beaten ſulphur, mercury, ſea-water, gold, copper, &c. but, above all, diamonds, which, when briſkly rubbed againſt glaſs, gold, or the like, yield a light equal to that of a live coal when blowed by the bellows. See ELECTRICS and ELECTRICITY.

FRICTION, in *Mechanics*, denotes the reſiſtance a moving body meets with from the ſurface on which it moves.

Friction ariſes from the roughneſs or aſperity of the ſurface of the body moved on, and that of the body moving; for ſuch ſurfaces conſiſting alternately of eminences and cavities, either the eminences of the one muſt be raiſed over thoſe of the other, or they muſt be both broke and worn off; but neither can happen without motion, nor can motion be produced without a force impreſſed. Hence, the force applied to move the body is either wholly, or partly, ſpent on this effect; and conſequently there ariſes a reſiſtance, or friction, which will be greater, *cæteris paribus*, as the eminences

nences are the greater, and the ſubſtance the harder: and as the body, by continual friction, becomes more and more poliſhed, the friction diminiſhes.

Hence it follows, that the ſurfaces of the parts of machines that touch each other ſhould be as ſmooth and poliſhed as poſſible. However, it is found by experience, that the flat ſurfaces of metals, or other bodies, may be ſo far poliſhed as to increaſe friction; becauſe the attraction of coheſion becomes ſenſible, as we bring the ſurfaces of bodies nearer and nearer to contact. But, as no body can be ſo much poliſhed, as quite to take away all inequality; witneſs thoſe numerous ridges diſcovered by the microſcope on the ſmootheſt ſurfaces; hence ariſes the neceſſity of anointing the parts that touch with oil, or ſome other fatty matter.

FRICTION, *Laws of.* 1. As the weight of a body moving on another is increaſed, ſo is the friction.

This we ſee experimentally in a balance, which, when only charged with a ſmall weight, eaſily turns; but with a greater, a greater force is required.

Hence, if the line of direction of a moving body be oblique to the ſurface moved on, the friction is the greater; this having the ſame effect as an increaſe of weight.

And hence, again, as a perpendicular ſtroke or impreſſion is to an oblique one, as the whole ſine to the ſine of the angle of incidence; and the ſine of a greater angle is greater, and that of a leſſer leſs; the friction is the greater, as the line of direction approaches nearer to a perpendicular.

This is eaſily obſervable, and eſpecially in the teeth of wheels, which are frequently broke on this very account. The friction, therefore, is taken away, if the line of direction of the moving body be parallel to the ſurface. The truth of this principle, that the friction is proportioned to the weight of the moving body, has been diſputed; and ſome objections have been urged againſt it, an account of which will be given in the ſequel of the article.

2. The friction is leſs in a body that rolls than it would be if the ſame body were to ſlide, as is eaſily demonſtrated. For ſuppoſe a dented ruler, A B, *Plate* XXIX. *Mechanics*, *fig.* 1. and ſuppoſe a wheel D E to move along with it, with its teeth perpendicular to the circumference; if now the body were to ſlide, the tooth F, when it touched the ruler, would deſcribe a right line on its ſurface, and, as the tooth of the ruler H reſiſts the ſame, it could not proceed without removing or breaking either the tooth H, or that at F. And the ſame will hold in the ſliding of any rough ſurface upon another, where the whole friction will take place that can any way ariſe from the roughneſs of the ſurface. But if the wheel E D roll along the ruler, then the tooth H will no longer reſiſt its motion, only as it is to be hoiſted out of the cavity F over the eminence of the tooth H; and the ſame holds in the rubbing of any rough body over the ſurface of another.

Hence, in machines, leſt the friction ſhould employ a great part of the power, care is to be taken, that no part of the machine ſlide along another, if it can be avoided; but rather that they roll, or turn upon each other. With this view it may be proper to lay the axes of cylinders, not as is uſually done, in a groove, or concave matrix, but between little wheels, A B C D, *fig.* 2. moveable on their reſpective axes; for by this contrivance, the friction is tranſferred from the circumference of thoſe wheels to their pivots; and the friction may be ſtill diminiſhed farther, by making the axles of thoſe wheels reſt upon other friction-wheels that turn round with them. This was long ago recommended by P. Caſatus; and experience confirms, that we ſave much power by it. Hence alſo it is, that a pulley moveable on its axis reſiſts leſs than if it were fixed. And the ſame may be obſerved of the wheels of coaches, and other carriages.

From theſe principles, with a little farther help from the higher geometry, Olaus Roemer determined the figure of the teeth of wheels, that ſhould make the leaſt reſiſtance poſſible, and which ſhould be epicycloidal. And the ſame was afterwards demonſtrated by De la Hire. See WHEELS and WHEEL-CARRIAGES.

Hence in ſawing mills, the ſides of the wooden rectangle the ſaws are fitted into ſhould be furniſhed with rotulæ, or little wheels, which would greatly leſſen the friction; and the like in other caſes.

FRICTION, *Calculation of the Quantity of.* The friction is a point of the utmoſt importance in machines; and by all means to be conſidered in calculating their force: yet it is generally overlooked in ſuch calculations: but this is principally becauſe its preciſe value is not known. It is not yet reduced to certain and infallible rules; ſince it depends upon the ſtructure of bodies, the form of their prominent parts and cavities, and upon their rigidity, their elaſticity, their coherence, and other circumſtances. The common method is, barely to compute the advantage which a moving power has from the machine; either on account of its diſtance from a fixed point; or of the direction in which it acts. And in all the demonſtrations it is ſuppoſed, that the ſurfaces of bodies are perfectly ſmooth and poliſhed. Indeed the engineers expect, that in the practice they ſhould loſe part of the advantage of their force by the friction; but how much, it is ſuppoſed, nothing but the practice can determine. M. Amontons, indeed, (Mem. de l'Acad. Royale des Sciences 1699), has made an attempt to ſettle, by experiment, a foundation for the preciſe calculation of the quantity of friction, and Mr. Parent has confirmed it from reaſoning and geometry; but their theory, however warranted, is not generally and fully received.

M. Amontons' principle is, that the friction of two bodies, or the reſiſtance oppoſed to the motion of a body upon an horizontal ſurface, depends on the weight, or force, with which they bear on each other; and only increaſes as the bodies are more ſtrongly preſſed, or applied, againſt each other, or are charged with a greater weight; and that it is a vulgar error, that the quantity of friction has any dependence on the extent of the ſurfaces rubbed againſt each other; or that the friction increaſes as the ſurfaces do. Thus if a piece of wood four inches wide and one inch thick be ground, and thereby made as exactly fit to the ſurface of another fixed piece of the ſame wood, it will acquire the ſame weight to draw it along on the ſame, whether it be laid on its broad or narrow ſide: for though on the broad ſide there be four times the number of touching particles (*cæteris paribus*), yet each particle is preſſed with but $\frac{1}{4}$ of the weight bearing on thoſe of the narrow ſide; and ſince four times the number multiplied by $\frac{1}{4}$ of the weight is equal to $\frac{1}{4}$ of the number multiplied by four times the weight, it is plain that the effect, that is, the reſiſtance, is equal in both caſes, and therefore requires the ſame force to overcome it.

Upon the firſt propoſal of this paradox, M. de la Hire had recourſe to experiments, which ſucceeded much in favour of the new ſyſtem. He laid ſeveral pieces of rough wood on a rough table; their ſizes were unequal; but he laid weights on them, ſo as to render them all equally heavy: and he found, that the ſame preciſe force, or weight, applied to them by a little pulley, was required to put each in motion, notwithſtanding all the inequality of the ſurfaces. The experiment ſucceeded in the ſame manner in pieces of marble, laid on a marble table. Upon this M. de

la Hire

la Hire betook himſelf to the rationale of the thing; and has given us a phyſical ſolution of the effect. And M. Amontons has ſettled a calculus of the value of friction; and the loſs ſuſtained by it in machines, on the foundation of the new principle.

In wood, iron, lead, and braſs, which are the principal materials uſed in machines, he finds the reſiſtance, cauſed by friction, to be nearly the ſame, when thoſe materials are anointed with oil, or other fatty matter; (but this fact has been diſputed by Muſchenbroek, and experiments urged in proof of the contrary:) and this reſiſtance, independent of the quantity of ſurface, he makes to be nearly equal to a third part of the force with which the bodies are preſſed againſt each other. Others have obſerved, that if the ſurfaces be hard and well poliſhed, the friction will be leſs than a third part of the weight; but if the parts be ſoft or rugged, it will be much greater. Let a very ſmooth cylinder of wood AB, *fig.* 3. be laid on two well-poliſhed and oiled or greaſed ſupporters C and D, and be charged with the weight of two pounds in the two equal balls G, H; it will require an additional weight x (equal to about a third part of the two pounds) to give motion to, or overcome the friction of the ſaid cylinder. But this additional weight, as it cauſes a greater preſſure of the cylinder, will increaſe the friction, and require the addition of another weight y, equal to a third part of its own; for the ſame reaſon the weight y will require another z a third part of two pounds, and ſo on *ad infinitum*.

Therefore, if the friction is preciſely equal to a third of the weight, the firſt weight, with all the additional ones, *viz.* 2, $\frac{2}{3}$, $\frac{2}{9}$, $\frac{2}{27}$, &c. will be a ſeries of numbers in geometrical progreſſion decreaſing: and the ſum of all theſe terms, omitting the firſt, *i. e.* the ſum of the infinite number of additional weights $x + y + z$, &c. equal to one pound: ſo that if the weight of the cylinder be inconſiderable, the way to overcome the friction will be to double the power G or H at once.

But if the cylinder moved on the two ſmall gudgeons E and F, or on a ſmall axis, the friction would be abated in the ſame proportion as the diameter of theſe gudgeons is leſs than the diameter of the cylinder, becauſe in this caſe the parts on which the cylinder moves and rubs will have leſs velocity than the power which moves it in the ſame proportion. See WHEEL *Carriages*.

Beſide the preſſion, the magnitude whereof determines that of the friction, there is another circumſtance to be conſidered, *viz.* the velocity. The friction is the greater, and the more difficult to ſurmount, as the parts are rubbed againſt each other with the greater ſwiftneſs; ſo that this velocity muſt be compared with that of the power neceſſary to move the machine, and overcome the friction. If the velocity of the power be double that of the parts rubbed, it acquires by that means an advantage that makes it double; or, which amounts to the ſame, it diminiſhes the contrary force of friction by one half; and reduces it to a ſixth part of the weight or preſſion. But this velocity M. Amontons only conſiders as a circumſtance that augments or diminiſhes the effect of the preſſion, *i. e.* the difficulty of the motion: ſo that the friction ſtill follows the proportion of the weight. Only, we are hereby directed to diſpoſe the parts of machines that rub againſt each other in ſuch a manner, as that they may have the leaſt velocity poſſible: and thus the diameter of the axis of a wheel ſhould be as ſmall as poſſible, with regard to that of the wheel; in that the leſſer the axis, the ſlower will be the motion of the ſurfaces rubbing againſt each other; ſince the velocity of a circular motion always goes diminiſhing from the circumference to the centre: and, for the ſame reaſon, the teeth of dented wheels ſhould be as ſmall and thin as poſſible; for a tooth catching on a notch, &c. rubs one of its ſides againſt a ſurface equal to its own; and is to diſengage itſelf, in a certain time, by paſſing over a ſpace equal to the ſurface; conſequently, the leſſer the ſurface, the leſs ſpace it has to move; the ſmallneſs of the ſurface diminiſhing the reſiſtance of the friction; not as it is a leſs ſurface that rubs, but as there is a leſs ſpace to move. The following general propoſition may be deduced from the preceding remarks, *viz.* That the reſiſtances ariſing from friction are to one another in a ratio compounded of the preſſures of the rubbing parts, and the times or velocities of their motions. The experiments of M. Amontons were confirmed by Boſſut and Belidor. (Archit. Hydraul. v. i. c. 2.) And thoſe of M. Bulfinger (Comment. Petropol. tom. ii.) furniſhed concluſions ſimilar to thoſe of Amontons, with this difference, that the reſiſtance of motion was equal to one-fourth of the force with which the rubbing ſurfaces were preſſed together. M. Parent, ſuggeſting that friction is occaſioned by ſmall ſpherical eminences in one ſurface being dragged out of correſponding ſpherical cavities in the other, propoſed to determine its quantity by finding the force which would move a ſphere ſtanding upon three equal ſpheres. Accordingly this force was found to be to the weight of the ſphere as ſeven to twenty, or nearly one-third of the ſphere's weight. (Recherches de Mathem. et Phyſ. 1713. tom. ii.) In inveſtigating the phenomena of friction, M. Parent placed the body upon an inclined plane, and augmented or diminiſhed the angle of inclination till the body had a tendency to move, and the angle at which the motion commenced, he called the angle of equilibrium. The weight of the body, therefore, will be to its friction upon the inclined plane as radius to the ſine of the angle of equilibrium, and its weight will be to the friction on an horizontal plane, as radius to the tangent of the angle of equilibrium. (Mem. de l'Academ. 1704.) The celebrated Euler ſeems to have adopted the hypotheſis of Bulfinger reſpecting the ratio of friction to the force of preſſion; and in two curious diſſertations, publiſhed by him on this ſubject, he has ſuggeſted many important obſervations, which have engaged the attention of profeſſor Vince. (Sur le Frottement des Corps Solides; and Sur la Diminution de la Reſiſtance du Frottement, publiſhed in the Memoires de l'Acad. Roy. des Sec. à Berlin. ann. 1748.) He obſerves, that when a body is in motion, the effect of friction will be only one-half of what it is when the body has begun to move; and he ſhews, that if the angle of an inclined plane be gradually increaſed till the body which is placed upon it begins to deſcend, the friction of the body at the commencement of its motion will be to its weight or preſſure upon the plane, as the ſine of the plane's elevation is to its coſine, or as the tangent of the ſame angle is to radius, or as the height of the plane is to its length. But when the body is in motion, the friction is diminiſhed, and may be found by the following equation, $\mu = \text{tang. } a \frac{m}{15623\, n\, n \text{ cof. } a}$; in which μ is the quantity of friction, the weight or preſſure of the body being $= 1$, a is the angle of the plane's inclination, m is the length of the plane in 1000dth parts of a Rhinland foot, and n the time of the body's deſcent. As to the cauſe of friction, Euler nearly agrees with Parent; with this difference, that inſtead of regarding the eminences and correſponding depreſſions as ſpherical, he ſuppoſes them to be angular, and imagines the friction to ariſe from the body's aſcending a perpetual ſucceſſion of inclined planes.

Notwithſtanding all the confirmations and illuſtrations of the

the theory of friction propoſed by Amontons, neither the public, nor even the academy itſelf where it was propoſed, could be brought fully to acquieſce in it. Muſchenbroek and the abbé Nollet have concluded from experiments that the friction of bodies depends on the quantity of their ſurface as well as their weight. (Introd. ad Phil. Nat. vol. i. cap. 9. and Lect. Phyſ. Exp. tom. i. p. 241.) Nollet (Leçons de Phyſique, tom. iii.) and Boſſut (Traité Elementaire de Mecanique, § 3067.) have diſtinguiſhed friction into two kinds, that which ariſes from one ſurface being dragged over another, and that which is occaſioned by one body rolling over another. The reſiſtance in the firſt caſe is greater than that in the ſecond; and it appears from the experiments of Muſchenbroek and others, that when a body is carried along with an uniformly accelerated motion, and retarded by the firſt kind of friction, the ſpaces are ſtill proportional to the ſquares of the times; but when the motion is effected by the ſame kind of friction, this proportionality between the ſpaces and the times of their deſcription does not obtain.

The above recited hypotheſis of M. Amontons has been adopted and confirmed by M. Camus, Deſaguliers, Ferguſon and others. Mr. Ferguſon found that the quantity of friction was always proportionable to the weight of the rubbing body, and not to the quantity of ſurface; and that it increaſed with an increaſe of velocity, but was not proportioned to the augmentation of celerity. He found alſo that the friction of ſmooth ſoft wood, moving upon ſmooth ſoft wood, was equal to $\frac{1}{3}$ of the weight; of rough wood upon rough wood $\frac{1}{2}$ of the weight; of ſoft wood upon hard, or hard upon ſoft, $\frac{1}{5}$ of the weight; of poliſhed ſteel upon poliſhed ſteel or pewter, $\frac{1}{4}$ of the weight; of poliſhed ſteel upon copper, $\frac{1}{5}$, and of poliſhed ſteel upon braſs $\frac{1}{6}$ of the weight. (See Ferguſon's Tables and Tracts.)

Mr. Emerſon, in his Principles of Mechanics, deduces from experiments the following remarks relating to the quantity of friction: when a cubic piece of ſoft wood of eight pounds weight moves upon a ſmooth plane of ſoft wood, at the rate of three feet per ſecond, its friction is about one third of the weight; but if it be rough, the friction is little leſs than half the weight: on the ſame ſuppoſition, when both the pieces of wood are very ſmooth, the friction is about one-fourth of the weight; the friction of ſoft wood on hard, or of hard wood upon ſoft, is one-fifth or one half of the weight; of hard wood upon hard wood one-ſeventh or one-eighth; of poliſhed ſteel moving on ſteel or pewter, one-fourth; moving on copper or lead, one-fifth of the weight. He obſerves in general, that metals of the ſame ſort have more friction than thoſe of different ſorts; that lead makes much reſiſtance; that iron or ſteel running in braſs makes the leaſt friction of any; and that metals oiled make the friction leſs than when poliſhed, and twice as little as when unpoliſhed. Deſaguliers obſerves that, in Monſ. Camus's experiments on ſmall models of ſledges in actual motion, there are more caſes wherein the friction is leſs than where it is more than one-third of the weight. See a table, exhibiting the friction between various ſubſtances, formed from his experiments in Deſ. Exp. Phil. vol. i. p. 193. See alſo his Account of the Friction of Engines, Carriages, &c. p. 133—138. p. 154—182. p. 458—460.

In order to eſtimate the quantity of friction in any engine, begin at the power and conſider the velocity and the weight at the firſt rubbing part, and determine the quantity of friction by the foregoing principles; then proceed to the next rubbing part, finding the friction there, &c.

There is ſcarcely any ſubject or experiment, with regard to which different perſons have formed ſuch various concluſions, ſo that the nature and laws of friction are not yet ſufficiently clear and deciſive. It is granted that the preſſion has a great effect, and is, in many caſes, the only thing to be conſidered in friction; but it will be hard to perſuade us abſolutely to exclude the conſideration of the ſurface.

If two bodies, with plain ſurfaces, ſuppoſed infinitely hard, and poliſhed, be moved along each other, the friction will be none, or infinitely ſmall; but if, in lieu of ſuch ſuppoſition, which has no place in nature, we ſuppoſe two bodies, with rough, uneven ſurfaces, the difficulty of moving one of them on the other muſt either ariſe from this; that the firſt is to be raiſed, in order to diſengage the parts catched or locked in the ſecond; or that the parts muſt be broken, and worn off; or both.

In the firſt caſe, the difficulty of raiſing one of the bodies makes that of the motion; and of conſequence the friction ariſes wholly from the weight, or preſſion; and the ſurface has nothing to do in it.

In the ſecond caſe, the magnitude of the ſurface would be all; were it poſſible this ſecond caſe could be abſolutely abſtracted from the firſt, *i. e.* could the parts of one body be rubbed and worn againſt thoſe of the other, without raiſing one of them; it being viſible, that a greater number of parts to be broken would make a greater reſiſtance than a leſs: but as in practice we never rub, or grind, without raiſing the body, the reſiſtance ariſing from the greatneſs of the ſurface in the ſecond caſe, is always combined with that from the preſſion; whereas, in the former caſe, that ariſing from the preſſion may be alone and uncompounded.

Add, that what is worn off a body is ordinarily very little, with regard to the great number of times the body muſt have been raiſed during the friction, and all the little heights added together, which the body muſt have been raiſed to.

Hence, as the reſiſtance from preſſion may be ſingle; and as the ſame always accompanies that ariſing from the magnitude of the ſurfaces, and is uſually much the more conſiderable of the two, when it does accompany it; for theſe reaſons, in moſt of the experiments that are made, it is the only one perceived, and the only one that needs to be conſidered.

But then, as it is poſſible, in certain caſes, for the preſſion to be very ſlender, and the number of parts to be rubbed very great, it muſt be owned there are caſes wherein the friction follows, very ſenſibly, the proportion of the ſurfaces.

The ſubject of friction is of ſuch importance in its relation to the conſtruction and uſe of various machines, that we think it needleſs to make any apology for extending this article, ſo as to comprehend ſome more recent facts and obſervations, which may enable thoſe whom it more immediately concerns to form a juſt eſtimate of its quantity, and to obviate its effects. The ingenious Mr. Vince of Cambridge has lately directed his attention to this intereſting ſubject; and communicated to the Royal Society an elaborate paper, containing a great number of experiments and of concluſions that are deduced from them, which merit particular notice. A minute detail would far exceed our limits; and, therefore referring our readers to the 75th volume of the Philoſophical Tranſactions, we muſt content ourſelves with briefly ſtating the general reſult of the whole. Mr. Vince found, by deduction from his experiments, that the friction of hard bodies in motion is an uniformly retarding force; and that the quantity of it is conſidered as *equivalent*

to

to a weight drawing the body backwards on the horizontal plane, or acting contrary to the moving force, is equal to $M - \frac{M \times W \times S}{r t^2}$; where M is the moving force expreſſed by its weight, W the weight of the body upon the horizontal plane, S the ſpace through which the moving force or weight deſcended in the time t expreſſed in ſeconds, and $r = 16\frac{1}{2}$ feet, the meaſure of the force of gravity. He alſo found that the quantity of friction increaſes in a leſs ratio than the quantity of matter or weight of the body; and that the friction of a body does not continue the ſame when it has different ſurfaces applied to the plane on which it moves, but that the ſmalleſt ſurfaces will have the leaſt friction. To the experiments inſtituted by Mr. Ferguſon and others, from which concluſions have been drawn ſo different from theſe, Mr. Vince makes the following objections; it was their object to determine what moving force would *juſt* put a body at reſt in motion; and having, as they thought, found it, they thence concluded, that the accelerative force was then equal to the friction. But it is manifeſt, as Mr. Vince obſerves, that any force which will put a body in motion muſt be *greater* than the force which oppoſes its motion, otherwiſe it would not overcome it; and hence, if there were no other objection but this, it is evident that the friction could not be very accurately obtained. Beſides, there is another objection which totally deſtroys the experiment ſo far as it tends to ſhew the quantity of friction, which is the ſtrong coheſion of the body to the plane when it lies at reſt; and this is confirmed by the following experiments: 1ſt, a body of $12\frac{3}{4}$ oz. was laid upon an horizontal plane, and then loaded with a weight of 8lb. and ſuch a moving force was applied as would, when the body was *juſt put* in motion, continue that motion without any acceleration; in which caſe the friction muſt be juſt equal to the accelerative force. The body was then ſtopped, when it appeared that the ſame moving force which had *kept* the body in motion before, would not *put* it in motion, and it was found neceſſary to take off, $4\frac{1}{2}$ oz. from the body before the ſame moving force *would put* it in motion: whence it appears that this body when laid upon the plane, at reſt, acquired a very ſtrong adheſion to it. 2dly. A body whoſe weight was 16 oz. was laid at reſt upon the horizontal plane, and it was found that a moving force of 6 oz. would juſt *put* it in motion, but that a moving force of 4 oz. *would*, when it was juſt put in motion, *continue* that motion without any acceleration, and therefore the accelerative force muſt *then* have been equal to the friction, and not when the moving force of 6 oz. was applied. From theſe experiments it appears, how very conſiderable the coheſion was in proportion to the friction when the body was in motion: it being, in the latter caſe, almoſt one-third, and in the former it was found to be very nearly equal to the whole friction. All the concluſions, therefore, deduced from the experiments which have been inſtituted to determine the friction from the force neceſſary to *put* a body in motion, have manifeſtly been totally falſe; as ſuch experiments only ſhew the reſiſtance which ariſes from the coheſion and friction jointly.

After all theſe details we muſt recur to the experiments and reaſoning of M. Coulomb for an accurate and ſatisfactory view of this complicated part of mechanical philoſophy. His experiments were conducted on a large ſcale, with large bodies and heavy weights, ſo that he was thus enabled not only to correct the errors which unavoidably aroſe from the limited experiments of preceding writers, but to diſcover new phenomena, while he confirmed other concluſions, which had before been partially eſtabliſhed. We ſhall here avail ourſelves of the reſults of his experiments, as they are preſented in an abridged form to the reader by Dr. Brewſter in his edition of Ferguſon's Mechanics, vol. ii. and refer for a fuller account to the "Journal de Phyſique" for Sept. and Oct. 1785, vol. xxvii. p. 206—282, &c.

1. The friction of homogeneous bodies, or bodies of the ſame kind moving upon one another, is generally ſuppoſed to be greater than that of heterogeneous bodies. This was the opinion of Muſchenbroek, Krafft, Camus, and Boſſut. But Coulomb has ſhewn that there are exceptions to this rule. He found, for example, that the friction of oak upon oak was equal to $\frac{1}{2 \cdot 34}$ of the force of preſſion; the friction of pine againſt pine was $\frac{1}{1 \cdot 78}$, and of oak againſt pine $\frac{1}{1 \cdot 5}$. The friction of oak againſt copper was $\frac{1}{5 \cdot 5}$, and that of oak againſt iron nearly the ſame.

2. It was generally ſuppoſed, that in the caſe of wood, the friction is greateſt when the bodies are dragged contrary to the courſe of their fibres. Muſchenbroek, Introductio ad Philoſoph. Nat. § 513, &c. But Coulomb has ſhewn that the friction is in this caſe ſometimes the ſmalleſt. When the bodies moved in the direction of their fibres the friction was $\frac{1}{2 \cdot 34}$ of the fibres with which they were preſſed together; but when the motion was contrary to the courſe of the fibres, the friction was only $\frac{1}{3 \cdot 76}$.

3. The longer the rubbing ſurfaces remain in contact, the greater is their friction. This is mentioned by Boſſut, Traite de Mecanique, § 310; but Coulomb has the merit of having eſtabliſhed the fact.—When wood was moved upon wood, according to the direction of the fibres, the friction was increaſed by keeping the ſurfaces in contact for a few ſeconds; and when the time was prolonged to a minute, the friction ſeemed to have reached its fartheſt limit. But when the motion was performed contrary to the courſe of the fibres, a greater time was neceſſary before the friction arrived at its maximum. When wood was moved upon metal, the friction did not attain its maximum till the ſurfaces continued in contact for five or ſix days; and it is very remarkable, that when wooden ſurfaces were anointed with tallow, the time requiſite for producing the greateſt quantity of friction is increaſed. The increaſe of friction which is generated by prolonging the time of contact is ſo great, that a body weighing 1650 pounds was moved with a force of 64 pounds when firſt laid upon its correſponding ſurface. After having remained in contact for the ſpace of three ſeconds, it required 160 pounds to put it in motion, and when the time was prolonged to ſix days, it could ſcarcely be moved with a force of 622 pounds. When the ſurfaces of metallic bodies were moved upon one another, the time of producing a maximum of friction was not changed by the interpoſition of olive oil; it was increaſed, however, by employing ſwines greaſe as an unguent, and was prolonged to five or ſix days by beſmearing the ſurfaces with tallow.

4. Friction is in general proportional to the force with which the rubbing ſurfaces are preſſed together; and is, for the moſt part, equal to between $\frac{1}{2}$ and $\frac{1}{4}$ of that force.—In order to prove the firſt part of this propoſition, Coulomb employed a large piece of wood, whoſe ſurface contained three ſquare feet, and loaded it ſucceſſively with 74 pounds, 874 pounds, and 2474 pounds. In theſe caſes the friction was ſucceſſively $\frac{1}{2 \cdot 46}$, $\frac{1}{2 \cdot 16}$, $\frac{1}{2 \cdot 21}$ of the force of preſſion;

preſſion; and when a leſs ſurface and other weights were uſed, the friction was $\frac{1}{2.36}$, $\frac{1}{2.42}$, $\frac{1}{2.40}$. Similar reſults were obtained in all Coulomb's experiments, even when metallic ſurfaces were employed. The ſecond part of the propoſition has alſo been eſtabliſhed by Coulomb. He found that the greateſt friction is engendered when oak moves upon pine, and that it amounts to $\frac{1}{1.78}$ of the force of preſſion; on the contrary, when iron moves upon braſs, the leaſt friction is produced, and it amounts to $\frac{1}{4}$ of the force of preſſion.

5. Friction is in general not increaſed by augmenting the rubbing ſurfaces. Muſchenbroek and Nollet entertained the oppoſite opinion. The experiments of Krafft coincide with thoſe of Coulomb. See Commentarii Petropolitanæ, tom. xii. p. 266, § 19, 20, &c.—When a ſuperficies of three feet ſquare was employed, the friction, with different weights, was $\frac{1}{2.28}$ at a medium; but when a ſmaller ſurface was uſed, the friction, inſtead of being greater, as might have been expected, was only $\frac{1}{2.39}$.

6. Friction for the moſt part is not augmented by an increaſe of velocity. In ſome caſes, however, it is diminiſhed by an augmentation of celerity.—M. Coulomb found, that when wood moved upon wood in the direction of the fibres, the friction was a conſtant quantity, however much the velocity was varied; but that when the ſurfaces were very ſmall in reſpect to the force with which they were preſſed, *the friction was diminiſhed by augmenting the rapidity:* the friction, on the contrary, was increaſed when the ſurfaces were very large when compared with the force of preſſion. When the wood was moved contrary to the direction of its fibres, the friction in every caſe remained the ſame. If wood is moved upon metals, the friction is greatly increaſed by an increaſe of velocity; and when metals move upon wood beſmeared with tallow, the friction is ſtill augmented by adding to the velocity. When metals move upon metals, the friction is always a conſtant quantity; but when heterogeneous ſubſtances are employed which are not bedaubed with tallow, the friction is ſo increaſed with the velocity, as to form an arithmetical progreſſion when the velocities form a geometrical one.

7. The friction of loaded cylinders rolling upon a horizontal plane is in the direct ratio of their weights, and the inverſe ratio of their diameters. In Coulomb's experiments, the friction of cylinders of guaiacum wood, which were two inches in diameter, and were loaded with 1000 pounds, was 18 pounds or $\frac{1}{56}$ of the force of preſſion. In cylinders of elm, the friction was greater by $\frac{2}{5}$, and was ſcarcely diminiſhed by the interpoſition of tallow.

From a variety of experiments on the friction of the axes of pullies, Coulomb obtained the following reſults.—When an iron axle moved in a braſs buſh or bed, the friction was $\frac{1}{5}$ of the preſſion; but when the buſh was beſmeared with very clean tallow, the friction was only $\frac{1}{11}$, when ſwine's greaſe was interpoſed, the friction amounted to $\frac{1}{8.5}$, and when olive oil was employed as an unguent, the friction was never leſs than $\frac{1}{9}$ or $\frac{1}{7.5}$. When the axis was of green oak, and the buſh of guaiacum wood, the friction was $\frac{1}{26}$ when tallow was interpoſed; but when the tallow was removed ſo that a ſmall quantity of greaſe only covered the ſurface, the friction was increaſed to $\frac{1}{17}$. When the buſh was made of elm, the friction was in ſimilar circumſtances $\frac{1}{31}$ and $\frac{1}{20}$ which is the leaſt of all. If the axis be made of box, and the buſh of guaiacum wood, the friction was $\frac{1}{21}$ and $\frac{1}{14}$, circumſtances being the ſame as before. If the axle be of boxwood, and the buſh of elm, the friction will be $\frac{1}{29}$ and $\frac{1}{25}$; and if the axle be of iron and the buſh of elm, the friction will be $\frac{1}{26}$ of the force of preſſion.

The cauſe of friction is well illuſtrated by Mr. John Leſlie, profeſſor of mathematics in the univerſity of Edinburgh. (See his valuable work on the nature and propagation of heat, chap. xv. p. 299, &c.) "If the two ſurfaces," ſays this ingenious writer, "which rub againſt each other are rough and uneven, there is a neceſſary waſte of force, occaſioned by the grinding and abraſion of their prominences. But friction ſubſiſts after the contiguous ſurfaces are worked down as regular and ſmooth as poſſible. In fact, the moſt elaborate poliſh can operate no other change than to diminiſh the ſize of the natural aſperities. The ſurface of a body, being moulded by its internal ſtructure, muſt evidently be furrowed, or toothed, or ſerrated. Friction is, therefore, commonly explained on the principle of the inclined plane, from the effort required to make the incumbent weight mount over a ſucceſſion of eminences. But this explication, however currently repeated, is quite inſufficient. The maſs which is drawn along is not continually aſcending; it muſt alternately riſe and fall: for each ſuperficial prominence will have a correſponding cavity; and ſince the boundary of contact is ſuppoſed to be horizontal, the total elevations will be equalled by their collateral depreſſions. Conſequently, if the lateral force might ſuffer a perpetual diminution in lifting up the weight, it would, the next moment, receive an equal increaſe by letting it down again; and thoſe oppoſite effects, deſtroying each other, could have no influence whatever on the general motion.

"Adheſion ſeems ſtill leſs capable of accounting for the origin of friction. A perpendicular force acting on a ſolid can evidently have no effect to impede its progreſs; and though this lateral force, owing to the unavoidable inequalities of contact, may be ſubject to a certain irregular obliquity, the balance of chances muſt, on the whole, have the ſame tendency to accelerate, as to retard, the motion. If the conterminous ſurfaces were, therefore, to remain abſolutely paſſive, no friction could ever ariſe. Its exiſtence demonſtrates an unceaſing mutual change of figure, the oppoſite planes, during the paſſage, continually ſeeking to accommodate themſelves to all the minute and accidental varieties of contact. The one ſurface, being preſſed againſt the other, becomes, as it were, compactly indented, by protruding ſome points and retracting others. This adaptation is not accompliſhed inſtantaneouſly, but requires very different periods to attain its *maximum*, according to the nature and relation of the ſubſtances concerned. In ſome caſes a few ſeconds are ſufficient, in others, the full effect is not produced till after the lapſe of ſeveral days. While the incumbent maſs is drawn along, at every ſtage of its advance, it changes its external configuration, and approaches more or leſs towards a ſtrict contiguity with the under ſurface. Hence the effort required to put it firſt in motion, and hence too, the decreaſed meaſure of friction, which, if not deranged by adventitious cauſes, attends generally an augmented rapidity. This appears clearly eſtabliſhed by the curious experiments of Coulomb, the moſt original and valuable which have been made on that intereſting ſubject. Friction conſiſts in the force expended to raiſe continually the ſurface of preſſure by an oblique action. The upper ſurface travels over a perpetual ſyſtem of inclined planes;

but that ſyſtem is ever changing, with alternate inverſion. In this act, the incumbent weight makes inceſſant, yet unavailing efforts to aſcend: for the moment it has gained the ſummits of the ſuperficial prominences, theſe ſink down beneath it, and the adjoining cavities ſtart up into elevations, preſenting a new ſeries of obſtacles which are again to be ſurmounted; and thus the labours of Siſiphus are realized in the phenomena of friction.

"The degree of friction muſt evidently depend on the angles of the natural protuberances, and which are determined by the elementary ſtructure or the mutual relation of the two approximate ſubſtances. The effect of poliſhing is only to abridge thoſe aſperities and increaſe their number, without altering in any reſpect their curvature or inflexions. The conſtant or ſucceſſive acclivity produced by the ever-varying adaptation of the contiguous ſurfaces remains, therefore, the ſame, and conſequently the expenſe of force will ſtill amount to the ſame proportion of the preſſure. The intervention of a coat of oil, ſoap, or tallow, by readily accommodating itſelf to the variations of contact, muſt tend to equalize it, and therefore muſt leſſen the angles, or ſoften the contour, of the ſucceſſively emerging prominences, and thus diminiſh likewiſe the friction which thence reſults."

In order to diminiſh the reſiſtance which friction occaſions in machines, that ſpecies of friction which ariſes from one body being dragged over another has been converted into that which is occaſioned by one body rolling upon another. This may be eaſily effected in the manner already mentioned in the beginning of this article, by applying wheels or rollers to the ſockets or buſhes which ſuſtain the gudgeons of large wheels, and the axles of wheel-carriages. This apparatus ſeems to have been firſt recommended by Caſatus (Mechan. l. ii. cap. 1.); and it was afterwards mentioned by Sturmius (Miſcell. Berol. tom. i. p. 306.) and Wolfius (Op. Mathem. tom. ii. p. 680.); but it was not uſed in practice till Sully applied it to clocks in the year 1716, and Mondran to cranes in 1725. However, friction-wheels were not much regarded till the celebrated Euler accurately explained their nature and advantages. (See Mem. de l'Acad. de Berlin 1743.)

The diameter of the gudgeons and pivots ſhould be made as ſmall as the weight of the wheel and the impelling force will permit. The gudgeons ſhould reſt upon two wheels as large as circumſtances will allow, having their axes as near each other as poſſible, but no thicker than what is abſolutely neceſſary to ſuſtain the ſuperincumbent weight. When theſe precautions are properly attended to, the reſiſtance which ariſes from the friction of the gudgeons, &c. will be extremely trifling. The effects of friction may likewiſe in ſome meaſure be removed by a judicious application of the impelling power, and by proportioning the ſize of the friction-wheels to the preſſure which they ſeverally ſuſtain. If we ſuppoſe, for example, that the weight of a wheel, whoſe iron gudgeons move in buſhes of braſs, is 100 pounds; then the friction ariſing from both its gudgeons will be equivalent to 25 pounds. If we ſuppoſe alſo that a force equal to 40 pounds is employed to impel the wheel, and acts in the direction of gravity, as in the caſe of overſhot wheels, the preſſure of the gudgeons upon their ſupports will thus be 140 pounds and the friction 35 pounds. But if the force of 40 pounds could be applied in ſuch a manner as to act in direct oppoſition to the wheel's weight, the preſſure of the gudgeons upon their ſupports would be 100—40, or 60 pounds, and the friction only 15 pounds. It is impoſſible indeed to make the moving force act in direct oppoſition to the gravity of the wheel, in the caſe of water-mills; and it is often impracticable for the engineer to apply the impelling power but in a given way; but there are many caſes in which the moving force may be ſo exerted, as at leaſt not to increaſe the friction which ariſes from the wheel's weight.

When the moving force is not exerted in a perpendicular direction, but obliquely, as in underſhot wheels, the gudgeon will preſs with greater force on one part of the ſocket than on any other part. This point will evidently be on the ſide of the buſh oppoſite to that where the power is applied, and its diſtance from the loweſt point of the ſocket, which is ſuppoſed circular and concentric with the gudgeon, being called x, we ſhall have tang. $x = \frac{H}{V}$, that is, the tangent of the arc contained between the point of greateſt preſſure and the loweſt point of the buſh, is equal to the ſum of all the horizontal forces, divided by the ſum of all the vertical forces and the weight of the wheel, H repreſenting the former, and V the latter quantities. The point of greateſt preſſure being thus determined, the gudgeon muſt be ſupported at that part by the largeſt friction-wheel, in order to equalize the friction upon their axles.

In the two following caſes friction-wheels have been ſucceſsfully employed. Mr. Gottlieb, the conſtructor of a new crane, has received a patent for what he calls an anti-attrition axle-tree, the beneficial effects of which he has aſcertained by a variety of trials. It conſiſts of a ſteel roller about four or ſix inches long, which turns within a groove cut in the inferior part of the axle. When wheel-carriages are at reſt, Mr. Gottlieb has given the friction-wheel its proper poſition; but it is evident that the point of greateſt preſſure will change when they are put in motion, and will be nearer the front of the carriage. This point, however, will vary with the weight of the load; but it is ſufficiently obvious that the friction-roller ſhould be at a little diſtance from the loweſt point of the axle-tree.

Mr. Gamett of Briſtol has applied friction-rollers in a different manner, which does not, like the preceding method, weaken the axle-tree. Inſtead of fixing the rollers in the iron part of the axle, he leaves a ſpace between the nave and the axis to be filled with equal rollers almoſt touching each other. The axes of theſe rollers are inſerted in a circular ring at each end of the nave, and theſe rings, and conſequently the rollers, are kept ſeparate and parallel by means of ſmall bolts paſſing between the rollers from one ſide of the nave to the other.

In wheel-carriages conſtructed in the common manner, with conical rims, there is a great degree of reſiſtance occaſioned by the friction of the linch pins on the external part of the nave, which the ingenious mechanic may eaſily remove by a judicious application of the preceding principles.

As it appears from the experiments of Ferguſon and Coulomb, that the leaſt friction is generated when poliſhed iron moves upon braſs, the gudgeons and pivots of wheels, and the axles of friction-rollers, ſhould all be made of poliſhed iron, and the buſhes in which theſe gudgeons move, and the friction-wheels, ſhould be formed of poliſhed braſs. M. de la Hire recommends the ſockets or buſhes to be made ſquare and not concave.

When every mechanical contrivance has been adopted for diminiſhing the obſtruction which ariſes from the attrition of the communicating parts, it may be ſtill farther removed by the judicious application of unguents. The moſt proper for this purpoſe are ſwine's greaſe and tallow, when the ſurfaces are made of wood, and oil when they are of metal. When the force with which the ſurfaces are preſſed together is very great, tallow will diminiſh the friction more than ſwine's greaſe. When the wooden ſurfaces are very ſmall, unguents will leſſen their friction a little, but it will be greatly

greatly diminiſhed if wood moves upon metal greaſed with tallow. If the velocities, however, are increaſed, or the unguent not often enough renewed, in both theſe caſes, but particularly in the laſt, the unguent will be more injurious than uſeful. The beſt mode of applying it, is to cover the rubbing ſurfaces with as thin a ſtratum as poſſible, for the friction will then be a conſtant quantity, and will not be increaſed by an augmentation of velocity.

In ſmall works of wood, the interpoſition of the powder of black lead has been found very uſeful in relieving the motion. The ropes of pulleys ſhould be rubbed with tallow, and whenever the ſcrew is uſed, the ſquare threads ſhould be preferred. (Ferguſon's Lectures by Brewſter, vol. ii.)

FRICTION *of Wheel-carriages*. See WHEEL-*carriages*.

FRICTION, in *Medicine* and *Surgery*, the act of rubbing the ſurface of the body, whether with the hand only, with the fleſh-bruſh, flannel, or other ſubſtances, or with oils, ointments, or other medicinal matters, with a view to the preſervation of health, or to the removal of particular diſeaſes.

Friction appears to have been much employed by the ancients as a ſort of gentle exerciſe for the purpoſe of preſerving the health and ſtrength of the body; and many directions have been left us by the phyſicians with reſpect to the times and modes of employing it, adapted to particular circumſtances. But, on the whole, theſe directions appear to be fanciful, and of little practical utility. (See Oribaſius, Medicin. Collect. lib. vi. cap. 13. 16—20.) Friction is conſidered by this author as chiefly efficacious in removing languor and laſſitude, and ſtrengthening the digeſtive powers, and the animal ſolids in general. It is recommended to be employed previous to any active exerciſe, with a view of ſoftening the muſcular parts and the ſkin, that they may not be ruptured or torn during the exertions (loc. cit. cap. 13, de frictione præparante); and again at the concluſion of active exerciſe, in order to remove the ſenſations of laſſitude, and to purge off all excrementitious matters. (Loc. cit. cap. 16. de apotherapia frictione.) We are told likewiſe that by hard rubbing the body is rendered firm; by gentle friction it is ſoftened; by frequent and long continued friction it is extenuated; and by a moderate degree the bulk is encreaſed. (Cap. 17.)

It cannot be queſtioned, that friction on the ſurface of the body produces an effect ſimilar to that of gentle exerciſe: it tends to excite the circulation through the veſſels of the ſkin, and conſequently through the reſt of the vaſcular ſyſtem; whence all the functions are more perfectly performed; the ſecretions are more freely elaborated; the appetite, therefore, is augmented; the digeſtion more completely effected, and the excretions, eſpecially that of perſpiration, more perfectly thrown off. (See EXERCISE.) In delicate habits the uſe of the fleſh-bruſh, or gentle rubbing with the hand, until ſome degree of glow is produced on the ſurface, may contribute, therefore, like riding or other ſpecies of geſtation, to ſupport or improve the health. The wholeſome effects of friction are well illuſtrated by the advantages of currying horſes: the benefits derived from it in theſe animals are generally conſidered as equivalent to half the feeding.

In this country, however, the principal employment of friction is directed to the cure rather than to the prevention of diſeaſes; and is generally accompanied by the uſe of ſome ſpecies of medicated oil, ointment, or lotion. Theſe auxiliaries are ſometimes poſſeſſed of medicinal qualities, which add to the efficacy of the friction; ſuch as the volatile or other ſtimulating liniments by which the vaſcular action of the part affected is more ſpeedily excited; but frequently they are of no eſſential ſervice, and are preſcribed partly to facilitate the proceſs of rubbing, by lubricating the parts, and partly to induce the patient and his attendants to perſevere in the practice of friction, who are too apt to ſuppoſe that the friction itſelf is uſeleſs, and to attribute the remedial effects to the lotion or liniment employed.

Friction is an efficacious remedy in ſeveral conditions of diſeaſe; particularly in chronic rheumatiſms of long ſtanding; in muſcular contractions, ſucceeding to rheumatiſm, &c. and connected often with effuſions of lymph; in ſome ſtates of paralyſis; in certain indolent tumours, &c. In theſe caſes, a variety of unguents and liniments is recommended; but the friction itſelf is the principal ſource of relief. In this manner a reſpectable practitioner in Oxfordſhire, Mr. Groſvenor, is ſaid to ſucceed in removing a number of diſeaſes, of the nature of thoſe juſt mentioned, by means of long continued friction with the hand alone: and an empiric of the name of Greatrakes, or Greatrix, formerly effected ſome cures that were deemed marvellous by this method of manual friction, which he called *ſtroaking*. (See Phil. Tranſ. No. 256.)

Friction is likewiſe employed with the view of introducing certain medicinal ſubſtances into the ſyſtem, through the medium of the abſorbent veſſels of the ſkin. Through theſe veſſels, which open upon the ſkin, but under the cuticle, the animal economy may be influenced by the peculiar properties of medicines; but friction is required to impel them through the inorganic pores of the ſcarf-ſkin, without which they are not abſorbed. In this way practitioners have been for a long time in the habit of employing one of the moſt active agents in the materia medica, *viz. mercury*, for the cure of the venereal diſeaſe. The advantages of this mode of impregnating the ſyſtem with mercury are very great in ſome conſtitutions; eſpecially in thoſe in which the ſmalleſt portion of mercury, conveyed into the inteſtines, acts as a purgative, and therefore cannot be thrown into the ſyſtem in ſufficient quantity to eradicate the diſeaſe, or without producing exceſſive miſchief by its cathartic operation. When the medicine is conveyed into the circulation, by means of the cutaneous abſorbents, this effect upon the alimentary canal is avoided.

Another active and uſeful drug has alſo been advantageouſly conveyed into the ſyſtem by means of external friction; we mean *opium*. The attention of the profeſſion has been lately called to this mode of adminiſtering opium by Mr. Ward of Mancheſter; from whoſe experience, ſupported by that of the late Dr. Percival of the ſame place, it appears, that the principal untoward conſequences which occaſionally reſult from the internal adminiſtration of this narcotic drug, in particular conſtitutions, and in certain ſtates of diſeaſe, eſpecially its diſagreeable effects on the head and the ſtomach, are avoided by introducing it through the abſorbents of the ſkin. In ſome caſes, too, as in that of locked jaw, whether from tetanus or hyſteria, when the mouth is ſo firmly cloſed, that nothing can be made to paſs to the throat, the external friction with opium is the only practicable mode of adminiſtering this important remedy. Dr. Percival found that opium, thus uſed, gave relief to patients afflicted with ſome chronic and painful diſorders, without occaſioning the head-ache, giddineſs, and coſtiveneſs which the internal uſe of laudanum had previouſly produced. In ſeveral caſes of the delirium of typhous fever, and of mania, opium thus employed was very efficacious. It was ſuppoſed by ſome Italian phyſicians, who firſt reſorted to the uſe of opium by

external friction, that a mixture with ſome animal fluid, ſuch as the ſaliva or gaſtric juice, was requiſite for the abſorption of the drug. (See Duncan's Annals of Medicine for 1798.) But Mr. Ward found that the tincture of opium alone, or formed into a liniment by means of the yolk of eggs, &c. was well adapted for abſorption; and that from three to ſix drachms of the tincture of opium, according to the age of the patient and the ſeverity of the diſeaſe, may be rubbed upon the inſides of the arms, until the whole is abſorbed. Sometimes he uſed an ointment, conſiſting of one part of finely powdered opium, with four or five parts of hogs' lard, and one or two of olive oil; and he obſerved, that the ſmaller the quantity of unguent the better, provided the whole be made ſo ſmooth and ſoft, as not to occaſion any uneaſineſs by its tenacity in applying the neceſſary degree of friction. (See Ward on the Efficay of Opiate Friction in Spaſmodic and Febrile Diſeaſes, 1809.)

FRIDAU, in *Geography*, a town of Auſtria; 4 miles S. of St. Polten.

FRIDAW, a town of the duchy of Stiria; 104 miles S. of Vienna. N. lat. 46° 27'. E. long. 16° 10'.

FRIDAY, the ſixth day of the week, ſo called from Friga, a goddeſs worſhipped by the Saxons on this day. It is a faſt-day in the church of England, in memory of our Saviour's crucifixion, unleſs Chriſtmas-day happens to fall on Friday, which is always a feſtival.

FRIDAY, *Good*, See PASSION-*Week*.

FRIDBERG, in *Geography*, a town of the duchy of Stiria; 43 miles S. of Vienna. N. lat. 47° 27'. E. long. 15° 53'.—Alſo, a town of Bavaria; 4 miles S. E. of Augſburg. N. lat. 48° 17'. E. long. 10° 58'.—Alſo, a town of Germany, in the Wetheraw, on the Erbach; formerly an Imperial town, till, in 1802, it was given to the landgrave of Heſſe-Darmſtadt; 12 miles N. of Frankfort on the Mayn. N. lat. 52° 20'. E. long. 8° 41'.

FRIDEK, or FRIEDEK, a town and lordſhip of Sileſia, in the principality of Teſchen; 10 miles S. W. of Teſchen. N. lat. 49° 52'. E. long. 18° 28'.

FRIDERICKSBERG, a fort and ſettlement on the coaſt of Guinea; 70 miles from Cape Coaſt caſtle.

FRIDEWALDE, a town of Germany, in the county of Sayn, a fief of Heſſe-Darmſtadt; 9 miles S. of Siegen.—Alſo, a town of Germany, in the principality of Heſſe-Caſſel; 35 miles S. S. E. of Caſſel.

FRIDINGEN, a town of Auſtrian Swabia, on the Danube; 20 miles S. E. of Tubingen.

FRIDLAND, or FRIEDLAND, a town of Pruſſia, in the province of Natangen, on the left bank of the Alle; 28 miles S. E. of Konigſberg. N. lat. 54° 24'. E. long. 21° 10'.

FRIDMAN, a town of Hungary; 17 miles N. N. W. of Palotza.

FRIDO, a town of Naples, in the Baſilicata; 7 miles E.S.E. of Potenza.

FRIDSTOLL, or FRITHSTOW, of the Saxon *frid*, peace, and *ſtol*, ſeat, in our *Ancient Writers*, ſignifies a ſeat, chair, or place of peace, where criminals might find ſafety and protection.

In the charter of immunities confirmed to the church of St. Peter in York, Ann. 5 H. VII. it is explained by "Cathedra quietudinis & pacis."

Of theſe there were many in England: but the moſt famous was at Beverley, which had this inſcription, "Hæc ſedes lapidea *Freedſtol* dicitur, *i. e.* Pacis Cathedra ad quam reus fugiendo perveniens, omnimodam habet ſecuritatem." Camden.

FRIEDBERG, in *Geography*, a town of Sileſia, in the principality of Neiſſe, on the Neiſſe; 14 miles S.S.W. of Neiſſe, N. lat. 50° 5'. E. long. 16° 15'.—Alſo, a town of Sileſia, in the principality of Jauer, on the Queis; 30 miles W. of Jauer. N. lat. 50° 52'. E. long. 15° 27'.—Alſo, a town of Sileſia, in the principality of Schweidnitz; 10 miles N:W. of Schweidnitz.—Alſo, a Moravian ſettlement in America, ſituated in Wachovia, or Surry county, N. Carolina.

FRIEDEBERG, a town of Germany, in the New Mark of Brandenburg; 45 miles N.E. of Francfort on the Oder. N. lat. 52° 56'. E. long. 15° 40'.—Alſo, a town of Eaſt Frieſland; 22 miles E.N.E. of Emden. N. lat. 53° 36'. E. long. 7° 48'.

FRIEDELAND, or BRILAN, a town of Lower Luſatia, on the Spree; 12 miles N.W. of Guben. N. lat. 52° 7'. E. long. 14° 12'.

FRIEDELSHAUSEN, a town of Germany, in the county of Henneberg; 7 miles N.W. of Meinungen.

FRIEDENSHUTTEN, a Moravian ſettlement in America, whoſe name ſignifies "tents of peace," ſeated on Suſquehanna river in Pennſylvania, about 24 miles below Tioga point, eſtabliſhed in 1765.

FRIEDERICK's FIORD, a bay of Weſt Greenland. N. lat. 62° 12'. W. long. 48° 20'.

FRIEDERICKSTADT, a town on the W. coaſt of the iſland of Santa Cruz. N. lat. 17° 48'. W. long. 93° 25'.

FRIEDLAND, a town of Sileſia, in the principality of Schweidnitz; 16 miles S.W. of Schweidnitz. N. lat. 50° 27'. E. long. 16° 3'.—Alſo, a Moravian ſettlement of America, in Wachovia.

FRIEDLAND, a town of Moravia, in the circle of Olmutz; 18 miles N.N.E. of Olmutz.—Alſo, a town of Bohemia, in the circle of Boleſlaw; 9 miles N.E. of Krottau.—Alſo, a town of the duchy of Meeklenburg; 14 miles N.E. of New Brandenburg. N. lat. 53° 39'. E. long. 13° 30'.—Alſo, a town of Sileſia, in the principality of Oppeln, on the Steinau; 20 miles S.W. of Oppeln. N. lat. 50° 25'. E. long. 17° 30.

FRIEDLINGEN, or FRIDLINGEN, a town and fort of Germany, in the circle of Swabia, near the Rhine, between Huningue and Bâle.

FRIELED, a town of Sweden, in the province of Smaland; 33 miles N.W. of Wexio.

FRIENDLESS MAN, was the old Saxon name for him whom we call an outlaw.

The reaſon is, becauſe he was, upon his excluſion from the king's peace and protection, denied all help of friends, after certain days. "Nam foris fecit amicos."

FRIENDLY COVE, in *Geography*, a harbour in Nootka ſound, on the N.W. coaſt of America, where a ſettlement was formed, in 1788, by Mr. Meares, and ſome other Engliſhmen, for the purpoſe of carrying on the fur trade. As this ſettlement occaſioned a ſerious diſpute between Spain and England, and very nearly terminated in a war between the two countries; we ſhall here ſtate ſome particulars relating to it, as they were communicated to us both by Capt. Vancouver, in the year 1792, and by Mr. Duffin, ſupercargo on board one of Mr. Meares's veſſels. Towards the cloſe of the year 1787, two veſſels were equipped for the fur trade, by John Henry Cox and Company, merchants at Canton. The conduct of the expedition was committed to Mr. Meares, who was alſo a joint proprietor. Theſe veſſels ſailed, with a view of avoiding certain heavy dues, under Portugueſe colours, and under the firm of John Cavallo, eſq., a Portugueſe merchant at Macao; but the veſſels and their cargoes were wholly Britiſh property, and navigated by ſubjects of his Britannic majeſty. In May 1788, Mr. Meares

Meares arrived in one of theſe veſſels at Nootka, and going on ſhore he purchaſed of the two chiefs, Maquilla and Calicum, the whole of the land that forms Friendly Cove, Nootka ſound, in his Britannic majeſty's name, for eight or ten ſheets of copper, and ſome triſling articles. The natives were perfectly ſatisfied, and did homage to Mr. Meares, as their ſovereign, according to the cuſtom of their country; the Britiſh, and not the Portugueſe, flags being diſplayed on ſhore during theſe ſolemn tranſactions. In conſequence of this compact, Mr. Meares ſelected a convenient ſpot on which he erected a houſe and adjoining buildings, and at his departure committed the care of it to Maquilla till his return. Mr. Duffin, on his return in July 1789, found the Cove occupied by the ſubjects of his Catholic majeſty, and could perceive no veſtiges of Mr. Meares's houſe. On the ſpot where it had ſtood were tents and houſes belonging to ſome people of the Columbia, commanded by Mr. J. Kendrick, under the flag and protection of the United States of America; his Catholic majeſty's ſhips, Princeſſa and San Carlos were at anchor in Friendly Cove, together with the Columbia and Waſhington, American traders: on the ſecond day after their arrival they were captured by Don Martinez; and the Americans were ſuffered to carry on their commerce with the natives, without moleſtation. Such is the ſubſtance of Mr. Duffin's declaration, atteſted by oath. In 1791 captain Vancouver was ſent out by the court of Great Britain to take poſſeſſion of Nootka ſound, according to an agreement with the court of Spain, and he arrived at Friendly Cove in Auguſt 1792. Signor Quadra, the commander of Nootka ſound, was willing to ſurrender Friendly Cove, but not the whole of the ſettlement, thus imagining verbally to fulfil the agreement between the two crowns. Vancouver demurred and would not allow, that the ceſſion propoſed by Signor Quadra was that intended in his commiſſion; but that at leaſt the whole port of Nootka, of which his Majeſty's ſubjects had been forcibly diſpoſſeſſed, and at which they themſelves, their veſſels, and cargoes, had been captured, muſt have been the propoſed object of reſtitution. Under theſe impreſſions Vancouver declined acceding to the propoſals of Quadra, conceiving that if he did he ſhould betray the truſt with which he was honoured. He was afterwards confirmed in the opinion, that he thus purſued the conduct, which, however it might terminate, was not incompatible with the truſt committed to his charge and execution. N. lat. 49° 35'. E. long. 233° 30'. See NOOTKA *Sound*.

FRIENDLY *Iſlands*, a group of iſlands, forming a kind of Archipelago of very conſiderable extent, and conſiſting of more than 150 in number; ſituated in the Southern Pacific Ocean, between 19° 40' and 21° 30' S. lat. and between 184° 46' and 185° 45 E. long. Some of theſe iſlands were diſcovered by Taſman in January 1642—3; and two of them in particular were called by him Amſterdam and Middleburg; but the former is called by the natives Tongatabu, and the latter Ea-oo-wee. Theſe two iſlands are ſituated between the latitude of 21° 29' and 21° 3' S. and between the longitude of 174° 40' and 175° 15' W. They were viſited by captain Cook, in April 1773, and again in October 1777. (See AMSTERDAM and MIDDLEBURG.)

To this cluſter of iſlands Cook gave the name of the Friendly Iſlands, or Archipelago, from the firm alliance and friendſhip which ſeemed to ſubſiſt among their inhabitants, and from their courteous behaviour to ſtrangers. The ſtay which captain Cook made at the Friendly Iſlands on his ſecond viſit was between two and three months; during which time, ſome accidental differences excepted, the utmoſt cordiality ſubſiſted between the Engliſh and the natives. Theſe differences were never attended with any fatal conſequences; which happy circumſtance was principally owing to the unremitting attention of the captain, who directed all his meaſures with a view to the prevention of ſuch quarrels as would be injurious either to the inhabitants or to his own people. Whilſt our navigators continued at theſe iſlands, they expended very little of their ſea proviſions, ſubſiſting, in general, upon the produce of the country, and carrying away with them a quantity of refreſhments ſufficient to laſt till their arrival at another ſtation, where they could depend upon a freſh ſupply. The captain left with theſe hoſpitable Indians ſeveral animals that would be uſeful to them. Many advantages obviouſly reſulted from this viſit; beſides the immediate benefits which both the natives and the Engliſh derived from their mutual intercourſe, ſuch a large acceſſion was made to the geographical knowledge of this part of the Pacific ocean, as cannot fail to be of ſervice to future navigators.

Under the denomination of the Friendly Iſlands muſt be included not only the group at *Hapaee* (which ſee), but all thoſe iſlands that have been diſcovered nearly under the ſame meridian to the North, as well as ſome others, which, though they have never hitherto been ſeen by any European voyagers, are under the dominion of Tongataboo. From the information received by captain Cook, this Archipelago appears to be very extenſive; above 150 iſlands were reckoned up by the natives, who made uſe of bits of leaves to aſcertain their number; and Mr. Anderſon, with his uſual diligence, procured all their names. Fifteen of them are ſaid to be high or hilly, ſuch as Toofoa and Eooa; and 35 of them large. Concerning the ſize of the 32 which were unexplored, we can only ſtate, that they muſt be larger than Annamoka, which was reckoned among the ſmaller iſles. Several, indeed, of thoſe which belong to this latter denomination are mere ſpots without inhabitants. Sixty-one of theſe iſles have their proper places and names marked upon the chart of the Friendly Iſlands, and the ſketches of the harbour of Tongataboo, which are given in Cook's Third Voyage, (vol. iii.) captain Cook had not the leaſt doubt but that Prince William's Iſlands, diſcovered or named by Taſman, were comprehended in the liſt furniſhed by the natives. He had alſo good authority for believing, that Keppel's and Boſcawen's Iſlands, two of captain Wallis's diſcoveries in 1765, were included in the ſame liſt; and that they were under the ſovereignty of Tongataboo, which is the grand ſeat of government. It muſt be left to future navigators to extend the geography of this part of the South Pacific ocean, by aſcertaining the exact ſituation and ſize of nearly 100 iſlands in the neighbourhood, which captain Cook had no opportunity of exploring. The ſoil in theſe iſlands is fertile, and in ſome of them highly cultivated, which, conſidering the imperfection of the agricultural implements, muſt have been attended with great labour. This labour, however, is amply rewarded by great produce. No one wants the common neceſſaries of life; in every face are painted joy and contentment. An eaſy freedom prevails among all ranks of people: they feel no wants which they do not enjoy the means of ſupplying; and they live in a clime, where the painful extremes of heat and cold are equally unknown. If nature has been in any reſpect deficient in its bounty, it is in the article of freſh water, which, being ſhut up in the bowels of the earth, muſt be procured by digging. A running ſtream was not ſeen, and but one well, at Amſterdam. At Middleburg, no water was ſeen beſides that which the natives had in veſſels; but this was ſweet and cool. The government of theſe iſlands

ſeems

ſeems to be monarchical, reſembling that of Otaheite. The king, or great chief, who is here called Areeke, has other chiefs under him, who are lords of certain diſtricts, and perhaps ſole proprietors, to whom the people appear to pay great reſpect and obedience. There is alſo a third rank, which has no ſmall degree of authority over the common people. Captain Cook thinks that all the land in Tongataboo is private property, and that there is here, as well as at Otaheite, a claſs of perſons who are ſervants or ſlaves, and who have no property in land. Their domeſtic animals are hogs and fowls; but they ſeem to have no dogs nor cats, nor any other wild quadrupeds, except ſmall lizards. The land birds are pigeons, turtle-doves, parrots, parroquets, owls, bald coots with a blue plumage, a variety of ſmall birds, and large bats in abundance. Their ſorts of fiſh ſeem to be the ſame with thoſe of the other iſles. Their fiſhing inſtruments are the ſame: that is, hooks made of mother of pearl, gigs with two, three, or more prongs, and nets made of a very fine thread, with the meſhes wrought exactly like ours. But their ingenuity is ſingularly conſpicuous in the conſtruction or form of their canoes, which exceeded every thing of the kind which captain Cook and his companions ſaw in that ſea. They are admirably adapted for diſtant navigation, as well as for the purpoſe of being veſſels of burden. Their working tools are made of ſtone, bone, ſhells, &c. as they are at the other iſlands; and their ingenious application of theſe tools excited admiration. Their knowledge of the utility of iron was barely ſufficient to teach them to prefer nails to beads, and ſuch trifles; ſome, but very few, would exchange a pig for a large nail, or a hatchet. Old jackets, ſhirts, cloth, and even rags, were in higher eſtimation among them than the beſt edged tool. The only piece of iron obſerved among them was a ſmall broad awl, which had been made of a nail.

The beſt articles for traffick, at theſe iſlands, are iron tools in general. Axes and hatchets; nails, from the largeſt ſpike down to tenpenny ones; raſps; files; and knives, are much ſought after. Sail cloth, and linen, both white and coloured, looking-glaſſes and beads, are alſo in eſtimation; but of the latter, thoſe that are blue are preferred to all others; as white ones are the leaſt valuable. A ſtring of large blue beads would, at any time, purchaſe a hog. In return for theſe favourite commodities, all the refreſhments may be procured which the iſlands produce. Theſe are hogs, fowls, fiſh, yams, bread-fruit, plantains, cocoa-nuts, ſugar-cane, and, in general, every ſuch article as can be met with at Otaheite, or any one of the Society Iſlands. The yams are excellent, and when grown to perfection, will keep well at ſea: but their pork, bread-fruit, and plantains are inferior in quality to thoſe of Otaheite, or its neighbourhood. Good water, as we have already obſerved, is ſcarce in theſe iſlands. The natives of the Friendly Iſlands ſeldom exceed the common ſtature, though ſome were above ſix feet; but they are very ſtrong, and well made, eſpecially as to their limbs. Their features are various; but the moſt diſtinguiſhing trait of the countenance is a fullneſs at the point of the noſe. Their eyes and teeth are good; but the latter are not ſo white nor ſo well ſet as thoſe generally obſerved among Indian nations. The women are deſtitute of that ſtrong fleſhy firmneſs which appears in the men. Their features indicate the delicacy of their ſex, and lay claim to a conſiderable ſhare of beauty and expreſſion. The bodies and limbs of moſt of the females are well proportioned, and ſome of them are perfect models of a beautiful figure. However, the moſt remarkable diſtinction of the women is the uncommon ſmallneſs and delicacy of their fingers, which vie with the fineſt in Europe. The general colour is a caſt deeper than the copper brown; but ſeveral of the men and women have a true olive complexion, and ſome of them are much fairer. But this may be owing to their being leſs expoſed to the ſun; as a tendency to corpulence among ſome of the principal people ſeems to be the conſequence of a more indolent life. The ſkin of the general maſs of the people is, more commonly, of a dull hue, with ſome degree of roughneſs, which may perhaps be occaſioned by ſome cutaneous diſeaſe. There are, however, few defects or deformities to be found amongſt them. But they are ſubject to a ſort of blindneſs, occaſioned by a diſeaſe of the cornea: to a kind of tetter or ring-worm; and to large broad ulcers, which in ſome caſes diſfigure them much and deſtroy the whole or part of the noſe. This ſeems to indicate venereal contagion, which is known to prevail amongſt them. There are two other diſeaſes frequent among them: one of theſe is an indolent firm ſwelling, which attacks the legs and arms, and cauſes them to ſwell to a very large ſize: and the other is a tumour of the ſame ſort in the teſticles. Upon the whole, they may, for the moſt part, be conſidered as a healthy people. They walk with a graceful air and firm ſtep; their countenances ſhew the mildneſs and good nature for which they are diſtinguiſhed: they are frank, cheerful, and good-humoured: though in the preſence of their chiefs they aſſume a grave or ſerious aſpect, which has the appearance of reſerve. Their diſpoſition is ſingularly peaceable, and they exerciſe hoſpitality and kindneſs to ſtrangers. They are well acquainted with the mode of trading by barter; and perhaps, ſays captain Cook, no nation in the world trafficks with more honeſty or leſs diſtruſt. Upon the whole, they ſeem to poſſeſs many of the moſt excellent qualities which adorn the human mind; ſuch as induſtry, ingenuity, perſeverance, affability, and probably other virtues which have eſcaped obſervation. The only defect that ſullies their character is a propenſity to thieving, which very much prevails among them, and which captain Cook candidly aſcribes to an intenſe curioſity or deſire to poſſeſs ſomething to which they had not before been accuſtomed, or that belonged to a ſort of people ſo different from themſelves. Their hair is in general ſtraight, thick, and ſtrong, and of a black colour; though it is ſometimes buſhy or frizzled, or ſtained of a brown, purple, or orange colour. Some have the hair cut off on one ſide, while on the other it remains long; ſome have it wholly cut off, except a ſingle lock on one ſide. The women, in general, wear it ſhort; and both men and women ſtrip the hair from their arm-pits. The men are ſtained from about the middle of the belly to about half down the thighs with a deep blue colour; which is done with a flat bone inſtrument, cut full of fine teeth, which being dipped in the colouring matter, is afterwards ſtruck into the ſkin with a ſtick, and thus indelible marks are made. Thus they have various lines and figures, which are very elegant, both from their variety and arrangement. The women have only a few ſmall lines or ſpots, thus imprinted in the inſide of their hands. Their kings are exempted from this cuſtom. The men are all circumciſed, or rather ſuperciſed; as the operation conſiſts in cutting off only a ſmall piece of the foreſkin, at the upper part, ſo that it is incapable of covering the glans; which operation they profeſſedly perform from a notion of cleanlineſs. A more extraordinary cuſtom prevails in theſe iſles, which is that of mutilating themſelves by the loſs of one or both of their little fingers. They alſo burn or make inciſions in their cheeks, near the cheek-bones. The dreſs of both the men and women conſiſts of a piece of cloth or matting, long enough to paſs once and a half round the waiſt, to which it is confined by

a girdle

a girdle or cord; it is double before, and hangs down like a petticoat, as low as the middle of the leg: the upper part above the girdle is plaited into ſeveral folds, ſo that, when unfolded, there is cloth ſufficient to draw up and wrap round the ſhoulders. The ornaments worn by perſons of both ſexes are amulets, necklaces, and bracelets of bones, ſhells, and beads of mother of pearl, tortoiſe-ſhells, &c. The women alſo wear on their fingers neat rings made of tortoiſe-ſhell, and pieces in their ears about the ſize of a ſmall quill. They have alſo a curious apron made of the outſide fibres of the cocoa-nut ſhell, and compoſed of a number of ſmall pieces ſewed together in ſuch a manner as to form ſtars, half-moons, little ſquares, &c. It is ſtudded with beads of ſhells, and covered with red feathers, ſo as to have a pleaſing effect. They are very attentive to perſonal cleanlineſs, and therefore frequently bathe in the ponds: nevertheleſs, the women rub themſelves all over with a yellow pigment, which ſeems to be a fine powder of turmeric, and they are ſo immoderately fond of cocoa-nut oil, that they pour it in great quantities upon their heads and ſhoulders, and rub their bodies over with it. The employment of the women is chiefly of the domeſtic kind, and the manufacture of their cloth is wholly conſigned to their care. This cloth is made of different degrees of fineneſs: the coarſer ſort receives no pattern, and of the fineſt ſort, they have ſome that is ſtriped and chequered, and differently coloured: their colours being black, brown, purple, yellow, and red, all procured from vegetables. Their cloth in general, which is made of the ſame materials as at Otaheite, will reſiſt water for ſome time; and they have a method of glazing it, which renders it in this reſpect preferable to that of Otaheite. They alſo manufacture various ſorts of matting, ſome of which is of a very fine texture, and uſed generally for clothing, whilſt the thicker and ſtronger ſort ſerves for ſleeping on, and for ſails to their canoes, &c. Among other uſeful utenſils, they have various ſorts of baſkets, ſome made of the ſame vegetable materials with their mats, and others of the twiſted fibres of cocoa-nuts. Theſe are not only durable, but beautiful, being generally compoſed of different colours, and ſtudded with beads made of ſhells or bones. The province of the men is more laborious and extenſive than that of the women; the objects of their care are agriculture, architecture, boat-building, fiſhing, and other articles relating to navigation. Their plantains and yams engage much of their attention and labour; and in cultivating them their inſtruments are merely pickets or ſtakes of different lengths, according to the depths which they have to dig. The cocoa-nut and bread-fruit trees, and ſome other trees which they plant, are diſperſed about in leſs order than the former, and ſeem to give them no trouble. In building their houſes, ingenious as they are in other reſpects, they diſplay little taſte. Thoſe of the lower people are poor huts, ſmall, and barely ſufficient to defend them from the weather. Thoſe of the better ſort are larger and more comfortable, but much inferior to what might be expected. Their houſe is, properly ſpeaking, a thatched roof or ſhed, ſupported by poſts and rafters; the floor is raiſed with earth ſmoothed, covered with ſtrong, thick matting, and kept very clean. Moſt of them are cloſed on the weather ſide with ſtrong mats, or branches of the cocoa-nut tree, plaited or woven into each other, and anſwering the purpoſe of a wall. A thick, ſtrong mat, bent into the form of a ſemicircle, envelopes a ſpace in which the maſter and miſtreſs of a family ſleep; the reſt of the family ſleep upon the floor; the unmarried men and women apart from each other. The ſervants retire in the night, when the family is large, to adjoining huts. Their whole furniture conſiſts of a bowl or two, a few gourds, cocoa-nut ſhells, ſmall wooden ſtools, which ſerve for pillows, and, perhaps, a large ſtool for the chief, or maſter of the family, to ſit upon. As they are fond of living much in the open air, they are leſs attentive to ornamental architecture. In naval architecture, however, they excel, as we may infer from the curious ſtructure of their canoes, already mentioned. The tools they uſe in the conſtruction of their boats are hatchets, or rather thick adzes, of a ſmooth black ſtone, that abounds at Toofoa; augres made of ſhark's teeth, fixed on ſmall handles; and raſps, of a rough ſkin of a fiſh, faſtened on flat pieces of wood. As knives, they uſe different ſhells. Their cordage is made from the fibres of the cocoa-nut huſk. The other manual employments conſiſt chiefly of making muſical reeds, flutes, warlike weapons, and ſtools or pillows, upon which they ſleep. Their reeds have eight, nine, or ten pieces placed parallel to one another, but not in any regular progreſſion, reſtricted commonly to ſix notes, but incapable of producing muſic diſtinguiſhable by the ears of Europeans. The flutes are a joint of bamboo, cloſe at both ends, with a hole beneath, and four others, two of which, and one of the firſt only, are uſed in playing. They apply the thumb of the left hand to cloſe the left noſtril, and blow into the hole at one end with the other. The middle finger of the left hand is applied to the firſt hole on the left, and the fore-finger of the right to the loweſt hole on that ſide: and thus, though the notes are only three, they produce a pleaſing, yet ſimple muſic, which they vary much more than one would think it poſſible, with an inſtrument ſo imperfect. They have alſo a drum, which may be compared to a hollow log of wood, about five feet ſix inches long, and thirty inches in girt, with a ſlit in it from the one end to the other, about three inches wide, by means of which it had been hollowed out. On the ſide of this log they beat with two drum-ſticks, and produce an hollow ſound, not quite ſo muſical as that of an empty caſk. Their weapons are clubs of different ſorts, and much ornamented, ſpears, and darts. They have alſo bows and arrows, deſigned merely for amuſement, ſuch as ſhooting at birds; and not for military purpoſes. Their ſtools are about two feet long, but only four or five inches high, and nearly four broad, bending in the middle, with four ſtrong legs and circular feet, all made of wood neatly poliſhed and ſometimes inlaid with bits of ivory.

The greateſt part of their vegetable diet conſiſts of yams, plantains, and cocoa-nuts. The chief articles of their animal food are hogs, fowls, fiſh, and all ſorts of ſhell-fiſh; but the lower people eat rats. Their food is generally dreſſed by baking, in the ſame manner as at Otaheite. At their meals they drink nothing but water, or the juice of the cocoa-nut. The women are not excluded from eating with the men; but there are certain orders or ranks among them, that can neither eat nor drink together. This diſtinction begins with the king. The time of their meals ſeems not to be fixed. They go to bed as ſoon as it is dark, and riſe with the dawn in the morning: but they frequently ſleep in the day. They are fond of ſociety, and frequently quit their houſes or huts for the purpoſe of converſing together, or engaging in other amuſements. Their private diverſions are chiefly ſinging, dancing, and muſic, performed by the women. When two or three women ſing in concert, and ſnap their fingers, it is called "oobai;" but when there is a greater number, they divide into ſeveral parties, each of which ſings in a different key, which makes very agreeable muſic, and is called "heeva" or "haiva." In the ſame manner they vary the muſic of their flutes, by playing on thoſe of a different ſize; but their dancing is much

much the ſame as when they perform publicly. The bulk of the people ſatisfy themſelves with one wife; but it does not appear whether their marriages are made laſting by any kind of ſolemn contract. The chiefs, however, have commonly ſeveral women, one of whom, as it was thought, was regarded as the miſtreſs of the family. The women in general appeared to be modeſt, though there is no want of thoſe of a different character. Such, however, appeared to be of the loweſt claſs, among whom were proſtitutes by profeſſion. The humanity of theſe people is ſtrikingly evinced by the concern they ſhew for their dead. Their mourning is expreſſed, not only by words but by deeds. They beat the teeth with ſtones, ſtrike a ſhark's tooth into the head until the blood flows in ſtreams, and thruſt ſpears into the inner part of the thigh, into their ſides below the arm-pits, and through the cheeks into the mouth. The deceaſed is buried after being wrapped up in mats and cloth, much after the European manner. The chiefs have the "fiatookas" appropriated to them as burial-places; but the common people are interred in no particular ſpot. They have long and general mourning, which indicates that they conſider death as a very great evil. And this is further confirmed by the very odd practice to which they reſort for averting it, which is that of cutting off one or both of their little fingers when they think themſelves in danger of dying; ſuperſtitiouſly ſuppoſing that the deity will accept of the little finger as a ſort of ſacrifice efficacious enough to procure the recovery of their health. They cut it off with one of their ſtone hatchets. From the rigid ſeverity with which ſome of their mourning and religious ceremonies are performed, it might be apprehended that they thus meant to ſecure to themſelves felicity beyond the grave; but their principal object relates to things temporal. However they ſeem, according to the account given of their religion by Mr. Anderſon, to entertain very proper ſentiments about the immateriality and immortality of the ſoul; and he thinks himſelf warranted in aſſerting, that they do not worſhip any thing that is the work of their own hands, or any viſible part of the creation. They nevertheleſs admit a plurality of ſubordinate deities, preſiding over the different elements of nature; and their notions of the future condition of the deceaſed are blended with many abſurdities. They do not make any offerings of hogs, dogs, and fruit, as at Otaheite, unleſs it be emblematically; for their "Morais" were perfectly free from every thing of the kind. But no doubt is entertained as to their offering real human ſacrifices. Their "Morais," or "fiatookas," are, as at Otaheite, and many other parts of the world, burying-grounds and places of worſhip; though ſome of them ſeemed to be only appropriated to the firſt purpoſe; but theſe were ſmall, and, in every other reſpect, inferior to the others. Their government, as we have before obſerved, is monarchical, but not deſpotic. A ſubordination ſeems to be eſtabliſhed among them, that reſembles the feudal ſyſtem of our progenitors in Europe. But, however independent on the deſpotic power of the king the great men, or chiefs, may be, people of the lower order have no property, nor ſafety for their perſons, but at the will of the chiefs to whom they belong. The inhabitants of Tongataboo, where the king reſides, call this iſland the "land of chiefs;" while the ſubordinate iſles are diſtinguiſhed by the appellation of "lands of ſervants." The chiefs are ſtyled by the people, not only lords of the earth, but of the ſun and ſky; and the king's family aſſume the name of "Futta-faihe" from the god ſo called, who is probably their tutelary patron, and perhaps their common anceſtor. There is a decorum obſerved in the preſence of their principal men, and particularly of their king, that is truly admirable. In addreſſing the king, they ſit down before him; and to ſpeak to the king ſtanding would be accounted here as a mark of rudeneſs. It does not appear, indeed, that any of the moſt civilized nations have ever exceeded theſe people in the great order obſerved on all occaſions; in ready compliance with the commands of their chiefs; and in the harmony that ſubſiſts through all ranks, and unites them, as if they were all one man, informed with, and directed by, the ſame principle. To their ſovereign they expreſs their reſpect and homage by every poſſible token of deference and ſubmiſſion. It appears, however, that if the king ſhould not govern according to law or cuſtom, the principal officer that preſides over the police would be ordered by the other great men, or by the people at large, to put him to death. A ſovereign thus liable to be controuled, and to be puniſhed for an abuſe of power, cannot be called a deſpotic monarch. When we conſider the number of iſlands that compoſe this little ſtate, and the diſtance at which ſome of them lie from the ſeat of government, attempts to throw off the yoke, and to acquire independency, it ſhould ſeem, might be apprehended. But this, it is ſaid, never happens. One reaſon why they are not diſturbed by domeſtic quarrels may be this: that all the powerful chiefs, whatever property they may poſſeſs in other iſlands, reſide at Tongataboo. They alſo ſecure the dependence of the other iſlands by the celerity of their operations; for if, at any time, a troubleſome and popular man ſhould ſtart up in any of them, the generaliſſimo or preſiding officer of the police, is immediately diſpatched thither to kill him: and they thus cruſh a rebellion in its infancy.

The common method of ſaluting one another in theſe iſlands is by touching or meeting noſes, as is done in New Zealand; and their token of peace to ſtrangers is the diſplay of a white flag or flags. A very ſingular cuſtom prevails among them of putting every thing you give them to their heads, by way of acknowledgment. This mode of paying a compliment is taught them from their infancy.

The language of the Friendly Iſlands has the greateſt affinity imaginable to that of New Zealand, of Wateeoo, and Mangeea; and conſequently to that of Otaheite, and the Society Iſlands. The mode of pronunciation differs; nevertheleſs a great number of words are either exactly the ſame, or ſo little changed, that their common original may be ſatisfactorily traced. Several hundred words were collected by Mr. Anderſon; and, amongſt theſe, are terms that expreſs numbers as far as a hundred thouſand; beyond which they would never reckon: for having proceeded thus far, they commonly uſed a word which expreſſes an indefinite number. Cooke's Second Voyage, vol. i. Cooke's Third Voyage, vol. i.

FRIENDLY *Societies* denote aſſociations, chiefly among the moſt induſtrious of the lower and middling claſs of tradeſmen and mechanics, for the purpoſe of affording each other relief in ſickneſs; and their widows and children ſome aſſiſtance at their death. Theſe have been thought worthy of the protection of the legiſlature, to prevent frauds which had ariſen from the irregular principles on which many of them were conducted.

The ſtatute 33 Geo. III. c. 54. provides that any number of perſons may form themſelves into a ſociety, and raiſe among themſelves a fund for their mutual benefit, and make rules and impoſe fines.—The rules, declaring the purpoſe for which ſuch ſocieties are eſtabliſhed, are to be exhibited to the quarter ſeſſions, who may annul or confirm them; in which latter caſe they are to be ſigned by the clerk of the peace. No rule thus confirmed is to be altered but at a general

general meeting of the ſociety, and ſubject to the controul of the ſeſſions. Societies may appoint officers, who are to give ſecurities for their truſt; the treaſurer or truſtees by bond to the clerk of the peace, and other perſons to the treaſurer or truſtees; which bonds are exempted from the ſtamp-duty. Committees of not leſs than eleven members may be appointed; their powers to be declared by the ſociety, and ſubject to their controul. Treaſurers and truſtees are enabled to lay out ſubſcriptions in purchaſe of ſtock, &c. and to ſell and change funds for the uſe of the ſociety; to render accounts, and pay over balances.—In caſe of miſbehaviour of truſtees, application is to be made to the court of chancery, in which proceedings are to be free of all expence of fees, ſtamps, &c. and counſel to be aſſigned gratis by the court. Executors or aſſignees of truſtees, &c. dying, or becoming bankrupt, to pay the demands of the ſociety in the firſt place. Effects of the ſocieties are veſted in treaſurers and truſtees, who may bring and defend actions.—Societies are not to be diſſolved without conſent of five-ſixths of the members.—Rules entered in a book are to be received as evidence.—Societies may receive donations.—Complaints of members againſt ſtewards, &c. are to be ſettled by two juſtices. If rules direct diſputes to be ſettled by arbitration, the award of the arbitrators ſhall be final.—Members of ſocieties producing certificates of ſteward, &c. are not to be removable till they become actually chargeable; and ſimilar proviſions are made relative to thoſe as to other certificates under the poor laws. See the article POOR.

FRIENDS, in *Eccleſiaſtical Hiſtory*, a denomination aſſumed by a reſpectable claſs of perſons, and which, as we are informed, they prefer to that of *Quakers*, by which they are alſo generally known. For an account of them, ſee QUAKERS.

FRIENDS *Alien*. See ALIEN.

FRIENDSHIP, in *Moral Philoſophy*, denotes that mutual attachment between different perſons, which proceeds from a cordial eſteem of the mental and moral qualities of one another; and which ſuppoſes, or produces, in a conſiderable degree, ſimilarity of diſpoſition and character, frequency of intercourſe, union of intereſts, and a reciprocity of confidence, good wiſhes, and kind offices. "Friendſhip," ſays Voltaire, "is a tacit contract between two ſenſible and virtuous perſons: *ſenſible*, I ſay; for a monk, or a hermit, may not be wicked, and yet may live a ſtranger to friendſhip. I add *virtuous*; for the wicked have only accomplices, the voluptuous have companions, the deſigning have aſſociates, the men of buſineſs have partners, the politicians form a factious band; the bulk of idle men have connections; princes have courtiers; but virtuous men alone have friends. Cethegus was Catiline's accomplice; and Mæcenas was Octavius's courtier; but Cicero was Atticus's *friend*." Without virtue there can be no genuine, permanent friendſhip, but whilſt thoſe eſtimable qualities ſubſiſt, that produce harmony of minds, and that bind true friends to each other, their friendſhip will continue, and will be rendered immortal.

Friendſhip, ſays lord Shafteſbury, is *that peculiar relation* which is formed by a conſent and harmony of minds, by mutual eſteem, and reciprocal tenderneſs and affection. Such was that between the two Jewiſh heroes, David and Jonathan. (2 Samuel, ch. i.) Such were thoſe friendſhips deſcribed ſo frequently by poets, between Pylades and Oreſtes, Theſeus and Pirithous, with many others. Such were thoſe between philoſophers, heroes, and the greateſt of men; between Socrates and Antiſthenes, Plato and Dion, Epaminondas and Pelopidas, Scipio and Lælius, Cato and Brutus, Thraſea and Helvidius.

The friendſhip of which we are now ſpeaking does not originate in ſelfiſh, intereſted views; and when it is formed and eſtabliſhed, it excludes ſuſpicion, jealouſy and reſerve, and is maintained by a free, candid, liberal intercourſe, which is not ſoon nor eaſily interrupted by diſcord, or which mutual explanation ſpeedily revives, and renewed affection perpetuates. This kind of friendſhip has been highly extolled by philoſophers, poets and divines, and they have concurred in deſcribing its excellence, enumerating its benefits, and recommending the cultivation and exerciſe of it. Lord Bacon has an excellent "Eſſay on Friendſhip;" and Dr. Young in his "Night Thoughts" thus deſcribes and recommends it:

"Friendſhip's the wine of life; but friendſhip new
——————————is neither ſtrong nor pure."

"Deliberate on all things with thy friend:
But ſince friends grow not thick on ev'ry bough,
Nor ev'ry friend unrotten at the core;
Firſt, on thy friend, delib'rate with thyſelf:
Pauſe, ponder, ſift; not eager in the choice,
Not jealous of the choſen; fixing, fix:
Judge before friendſhip, then confide till death."

Lord Shafteſbury (ubi ſupra) animated, ſays an ingenious writer, with a warm ſenſibility of the moral charms of this generous affection, and not being able, it ſeems, to diſcover that it is either enjoined or encouraged by the Chriſtian inſtitution, imputes this pretended omiſſion as a capital defect in the code of evangelical ethics. On the contrary, a late ingenious advocate for that ſacred cauſe, which it was the unhappy direction of this accompliſhed nobleman's learning and talents to depreciate; far from diſcerning any thing laudable or meritorious in private friendſhip, has attempted to prove, that "it is totally incompatible with the genius and ſpirit of the goſpel." Thus the very ſame ſuppoſed circumſtance which appears to have been no inconſiderable obſtruction to the noble philoſopher's faith, is aſſigned by the elegant defender of Chriſtianity, as one of thoſe internal marks which authenticate its divine origin! The ſame mode of reaſoning, however, which overturns either of the reſpective poſitions of theſe admired writers, will equally confute both. That private friendſhip does not expreſsly enter into the precepts of Chriſtianity, is unqueſtionably true; for the nature of the connection neceſſarily excludes it from being the ſubject of a religious or moral obligation. The diſtinctive character of this relation conſiſts in a ſpontaneous ſentiment of the heart, unconſtrained and uninfluenced by compulſive or external motives of every kind and degree. To attempt therefore to produce a voluntary affection, by the authority of a poſitive command, would be to publiſh a law evidently deſtructive of its own end; for its ſanctions could no ſooner operate as a primary, or determining inducement, than the ſentiment they were deſigned to create would thereby be prevented from exiſting. Beſides, a general ordinance for this purpoſe would not merely be abſurd, it would be unjuſt; becauſe it would require univerſally what is not in every man's power to perform. A great variety of circumſtances muſt concur to form and cement this union; and theſe are of a nature ſo exceedingly contingent and fortuitous, that they are frequently never realized in the courſe of the longeſt life. Indeed, they ſo rarely meet together, that what a ſagacious obſerver of mankind remarks concerning love, holds equally true in reſpect to *friendſhip*: "Il eſt du *veritable* comme de l'apparition des eſprits: tout le monde en *parle*, mais peu de gens ont *vû*."

Moreover, if what the noble author requires from revelation is, in the firſt inſtance, inconſiſtent with the eſſential na-

ture of its object, it implies, in the next place, an aſſertion no leſs contrary to fact; for although friendſhip could not, either in reaſon or juſtice, have been commanded by the precepts, it is evidently encouraged by the ſpirit of Chriſtianity; univerſal benevolence, or good will to mankind, is the vital principle that animates and pervades the whole ſyſtem of evangelical morality; and it is by a proper cultivation of this enlarged and comprehenſive virtue, that the heart is beſt prepared and qualified to enter into the engagements, and diſcharge the offices of private friendſhip. This the noble moraliſt himſelf acknowledges in another place. "Do you think," he ſays, "that particular friendſhip can well ſubſiſt without ſuch an enlarged affection and ſenſe of obligation to ſociety?" This kind of reaſoning, however, when applied to revelation, will not ſatisfy his demands; he contends that "friendſhip is no eſſential part of a Chriſtian's charity." But if there were any force in this objection, it would overſhoot its intended aim, and wound natural religion no leſs than revealed; as friendſhip, for the reaſons above aſſigned, can no more be the eſſential part of a theiſt's benevolence, than it is of a Chriſtian's.

It deſerves alſo to be conſidered, that our bleſſed Lord acted wiſely in not inculcating, by expreſs and poſitive command, private friendſhip, though he recommended it generally both by his doctrine and example. His commiſſion was primarily addreſſed to the Jews, and his religion was deſigned to aboliſh all thoſe diſtinctions of nation, party, and external privilege, that ſeparated between them and the Gentile world. The Jews were prone to indulge ſelfiſh and limited affections, and to reſtrict their benevolence to perſons of their own nation and profeſſion. Our Lord therefore very wiſely declines to recommend by poſitive law private friendſhip, and inculcates univerſal benevolence as beſt adapted to the diſpoſitions and circumſtances of the Jewiſh people, and as the moſt ſuitable preparation for the introduction of the Gentiles to a participation in common with the Jews, of the benefits and privileges which he was empowered to impart.

We may obſerve, however, that it is not ſolely by neceſſary implication, or circumſtantial inferences, that the Chriſtian revelation recognizes friendſhip. It ſtrongly and expreſsly recommends and encourages this amiable alliance; if, exhibiting it in the nobleſt and moſt animating examples may be allowed to have an immediate and direct influence over the heart of man. Two very remarkable inſtances for this purpoſe occur in the hiſtory of our Saviour's life. The Evangeliſt, in relating the miracle which Chriſt performed at Bethany, by reſtoring a perſon to life, who had lain ſome days in the grave, introduces his narrative by emphatically obſerving that "Jeſus loved Lazarus," intimating, it ſhould ſeem, that the ſentiments which Chriſt entertained of Lazarus were a diſtinct and peculiar ſpecies of that general benevolence with which he was actuated towards all mankind. Accordingly the ſiſters of Lazarus did not mention his name, but pointing him out to Jeſus by a more honourable and equally notorious deſignation, the terms of their meſſage were, "Behold! He whom thou loveſt is ſick." And when our Lord informs his diſciples of the notice he had thus received, his expreſſion is, "Our friend Lazarus ſleepeth." We obſerve that Chriſt did not upon this occaſion uſe the word "friend" in its looſe, undiſtinguiſhing acceptation, but in a reſtrained, and ſtrictly appropriated ſenſe; as is manifeſt, not only from this plain account of the fact itſelf, but as the ſequel farther evinces. For, as he was advancing to the grave, accompanied with the relations of the deceaſed, he diſcovered the ſame emotions of grief as ſwelled the boſoms of thoſe with whom Lazarus had been moſt intimately connected; and ſympathizing with their common ſorrow, he melted into tears. This circumſtance was too remarkable to eſcape particular obſervation; and it drew from the ſpectators, what we ſhould think it muſt neceſſarily draw from every reader, this natural and obvious reflection, "behold! how he loved him!"

But in the concluding cataſtrophe of our Saviour's life, he gave a ſtill more deciſive proof that ſentiments of the ſtrongeſt perſonal attachment and friendſhip were not unworthy of being admitted into his ſacred boſom; they were too deeply, indeed, impreſſed, to be extinguiſhed even by the moſt excruciating torments. In thoſe dreadful moments, obſerving among the afflicted witneſſes of his painful and ignominious ſufferings, that faithful follower, whom he had ſelected as his friend out of the ſmall band of his twelve apoſtles, and who is deſcribed by the hiſtorian as "the diſciple whom he loved;" he diſtinguiſhed him by the moſt convincing inſtance of ſuperior confidence, eſteem, and affection that was ever exhibited to the admiration of mankind. For, under circumſtances of the moſt agonizing torments, when it might be thought impoſſible for human nature to retain any other ſenſibility but that of its own inexpreſſible ſufferings, he recommended to the care and protection of this his tried and approved friend, in terms of peculiar regard and endearment, the moſt tender and ſacred object of his private affections. But no language can repreſent this pathetic and affecting ſcene with a force and energy equal to the ſublime ſimplicity of the evangeliſt's own narrative: "Now there ſtood by the croſs of Jeſus his mother, and his mother's ſiſter, and Mary Magdalen. When Jeſus ſaw his mother, and the diſciple ſtanding by, whom he loved; he ſaith to his mother, behold thy ſon! then he ſaith to the diſciple, behold thy mother! And from that hour that diſciple took her to his own home." It may ſafely be aſſerted, that among all thoſe memorable examples of friendſhip which have been celebrated with the higheſt encomiums by the ancients, there cannot be produced a ſingle inſtance in which the moſt diſtinguiſhing features of exalted amity are ſo ſtrongly diſplayed, as in the foregoing relation. The only one, perhaps, that bears even a faint ſimilitude to it, is that famous tranſaction recorded by a Greek author, which paſſed between Eudamidas and Aretheus. But when the very different circumſtances attending the reſpective examples are duly conſidered, it muſt be acknowledged that the former riſes as much above the latter in the proof it exhibits of ſublime friendſhip, as it does in the dignity of the characters concerned.

Upon the whole then it appears, that the divine founder of the Chriſtian religion, as well by his own example as by the ſpirit of his moral doctrine, has not only encouraged but conſecrated friendſhip. We are indebted for moſt of the preceding obſervations to the ingenious William Melmoth, eſq. in the concluding note to his elegant tranſlation of Cicero's "Lælius," or, "An Eſſay on Friendſhip, by Marcus Tullius Cicero," with remarks, p. 328—343.

FRIESLAND,

FRIESLAND, one of the ſtates or departments of Holland, ſo called from the Friſons, an ancient warlike people, whoſe country formerly extended from the Scheldt to the Weſer. (See Frisons.) It is bounded on the north by the German ocean, on the eaſt by Groningen and Overyſſel, on the ſouth by Overyſſel and the Zuyder ſea, and on the weſt by the Flie or Vlie river. Frieſland, particularly in its N.W. parts, which lie lower than the ſea, reſembles Holland in its air and ſoil, and is famous for its paſtures, ſupplying butter in ſuch quantities as to be a ſtaple article of commerce, and breeding excellent oxen, cows, and ſheep, and alſo large horſes. In the more elevated parts there is ſome good corn land, which affords wheat that has been held in eſtimation for the fineneſs of the ear, and the whiteneſs of the flour. The chief article of fuel is peat, and towards the ſouth and ſouth-eaſt there are extenſive heaths and foreſts of wood. For want of ſand-hills near the coaſt this country is defended at a great expence from the encroachments of the ſea by dykes. The canals of Frieſland are numerous; and ſerve not only for carrying off the ſuperfluous waters into the ſea, but for the purpoſes of commerce. The principal of theſe reaches from Harlingen through Francker as far as Leewarden, the capital of the country, and Dokkum, and Groningen, and even to the frontiers of Eaſt Frieſland. The whole province contains 11 towns and 336 villages. The inhabitants long retained that love of liberty and martial ſpirit which diſtinguiſhed their anceſtors, and many of thoſe cuſtoms, and that mode of living, which were tranſmitted to them from their progenitors; they have alſo preſerved among them the old Friſian dialect and accent, which renders the language of the country people unintelligible to the other Hollanders. Frieſland is famous for its woollen ſtuffs, and more eſpecially for its linen, which is the fineſt in Europe. This province, being a part of the ancient Friſia, had formerly princes of its own, afterwards dukes, and then kings: among whom Radbold II. was particularly celebrated. Theſe laſt were ſucceeded by podeſtats, ſelected from among the people. In the year 1436 part of Frieſland devolved to the houſe of Burgundy. In 1498 the emperor Maximilian I. created duke Albert of Saxony hereditary governor of Frieſland, under a ſtipulation that he ſhould maintain their ancient liberties; nevertheleſs they would never acknowledge him. In 1515 Charles V. purchaſed of George duke of Saxony his claim to this country, and ſubjected it to his own dominions; but under his ſon Philip II. the Friſons recovered their liberty, and acceded to the alliance of Utrecht. Since the United Provinces have been erected into a kingdom, and aſſigned by the emperor of France to his brother Louis, Frieſland forms a part of this treaty; and by the new conſtitutional code ſends three members to the legiſlative body. What farther changes await it, time muſt diſcloſe.

Friesland, *Eaſt*, a principality of Germany belonging to Pruſſia, is bounded on the north by the ſea, on the eaſt by the county of Oldenburgh, on the ſouth by the biſhopric of Munſter, and on the weſt by Groningen; about 38 miles from north to ſouth, and 36 from eaſt to weſt. The population, according to Hoeck, conſiſts of 102,594 perſons. The air, though moiſt and thick, is purified by ſea breezes; the ſpring and harveſts are late; the land is flat and low, and defended againſt the ſea by ſtrong and lofty dykes. Along the coaſt the ſoil is rich and fertile, and the land conſiſts chiefly of meadows, with ſome few corn fields. The cattle, ſheep, and horſes are of a large ſize and good quality. The butter and cheeſe are abundant and rich. The central part of the country is generally ſandy, interſperſed with fens and moors, whence the inhabitants ſupply themſelves with peat for fuel, as wood is ſcarce. The country abounds with game and fowl; and its geeſe are of an uncommonly large ſize. One-third part of this principality is uncultivated. The chief river is the Ems, which contributes to render the trade and navigation of this province very conſiderable. The exportation principally conſiſts in large horſes, horned cattle, cheeſe, butter, oats, beans, rape-ſeed, and fine linen. Anciently Eaſt Frieſland was divided into a great number of lordſhips, moſt of which ſubmitted, in the year 1430, to Edzard, ſurnamed Cyrkſena or Syrkſena, whoſe ſucceſſors became princes of the empire in 1454, under the title of count. After this family had become extinct, Frederick II. king of Pruſſia, in 1744, ſeized on the province, in conſequence of an expectancy granted to the houſe of Brandenburg by the emperor Leopold in the year 1694. But George II. king of England, being of the houſe of Brunſwick Luneburg, proteſted, and claimed the principality, on account of an hereditary union entered into in the year 1691, with prince Chriſtian Eberhard; and made known his pretenſions to the regency of Eaſt Frieſland, and to the Aulic chamber of the empire. However, the king of Pruſſia, denying the authority of the emperor and regency, and threatening to ſupport his claim by force of arms, was permitted to remain in undiſturbed poſſeſſion. The inhabitants are Lutherans and Calviniſts; but the Catholics enjoy toleration in many towns, and the Moravians at Emden, Leer, and Norden. The Jews are alſo tolerated. The nobility, lords, and peaſants form the ſtates, whoſe tranſactions with their princes, joined to the imperial ordinances, ſerve for the laws of the country. The ſtates conſent to taxes and raiſe them; the revenue of the ſovereign is about 300,000 rix-dollars. The principal towns are Aurich, Norden, and Emden.

FRIESLANDERS, in *Eccleſiaſtical Hiſtory*, a ſect of moderate Anabaptiſts, deriving their name from Frieſland, the country which they inhabit. See Waterlandians.

FRIEZE, Frize, or Freeze. See Freeze.

FRIGATE, in *Sea Affairs*, a ſhip of war, uſually of two decks, light built, deſigned for ſwift ſailing. When it hath but one deck, and conſequently is of a ſmaller ſize, they call her a light frigate.

Frigates mount from twenty to thirty-eight guns, and are eſteemed excellent cruiſers. The name was formerly known only in the Mediterranean, and applied to a long kind of veſſel, navigated in that ſea with ſails and oars. The Engliſh were the firſt who appeared on the ocean with theſe ſhips, and equipped them for war as well as for commerce.

Frigate-*built* denotes the diſpoſition of the decks of ſuch merchant ſhips as have a deſcent of four or five ſteps from the quarter deck and fore-caſtle into the waiſt, in contradiſtinction to thoſe whoſe decks are on a continued line for the whole length of the ſhip, which are called galley-built. See *Fluſh*-Deck.

Frigate-*bay*, in *Geography*, a bay on the S. coaſt of the iſland of St. Chriſtopher; two miles E.S.E. of Baſſeterre.

FRIGATOON, a Venetian veſſel, commonly uſed in the Adriatic, built with a ſquare ſtern, and without any fore-maſt, having only a main-maſt, mizen-maſt, and bowſprit.

FRIGENO, in *Geography*, a town of Italy, in the department of the Adda and Oglio; ſeven miles N.N.E. of Breno.

FRIGENTUM, in *Ancient Geography*, a town of Italy, E. of Eclana or Æculænum, to which it ſucceeded in power.

FRIGERATORY, among *Builders*, denotes a place intended to keep things cool in ſummer.

FRIGHT, a ſudden and violent degree of fear. (See FEAR.) This paſſion has been known not only to cauſe, but to cure diſeaſes. Epilepſy, ſtupor, madneſs, &c. have in ſome inſtances been produced by frights. Mr. Boyle mentions agues, gout, and ſciatica, cured by this means. It is a commonly known cure for the hiccough, to put the patient in a ſudden fright.

FRIGID, FRIGIDUS, *cold*, is variouſly uſed. A frigid ſtyle, is a low, jejune manner of diction; wanting force, warmth of imagination, figures of ſpeech, &c. This, and the bombaſt, are the two chief faults oppoſite to the *ſublime*, which ſee. The frigid conſiſts in degrading an object, or ſentiment, which is ſublime in itſelf, by our mean conception of it, or by our weak, low, and childiſh deſcription of it; this betrays entire abſence, or at leaſt great poverty of genius. Of this there are numerous examples commented upon with much humour, in the treatiſe on the art of ſinking, in Dean Swift's works; the inſtances being taken chiefly from ſir Richard Blackmore. The *Bombaſt* (which ſee) lies, in forcing an ordinary or trivial ſubject out of its rank, and endeavouring to raiſe it into the ſublime; or in attempting to exalt a ſublime object beyond all natural and reaſonable bounds. Writers of genius may ſometimes fall into this error, which is too common, by unluckily loſing ſight of the true point of the ſublime. This is alſo called *Fuſtian*, or *Rant*. Shakeſpeare is not altogether unexceptionable in this reſpect. Dryden and Lee, in their tragedies, abound with it.

FRIGID *Zone*, or *Frozen Zone*, in *Geography*. See ZONE.

FRIGIDITY is alſo uſed in the ſame ſenſe with impotence.

FRIGIDUS, in *Ancient Geography*, a river of Italy, in Venetia, which roſe in the Alpes Carnicæ, ran towards the weſt, watered a place called Caſtra, and diſcharged itſelf into the Sontius near Pons Sontii.

FRIGILIORA, in *Geography*, a town of Spain, in Grenada; 13 miles E. of Velez Malaga.

FRIGNANO, a town of Italy, in the department of the Panaro; 15 miles S. of Modena.

FRIGORIFIC, of *frigus*, *cold*, and *facio*, *I make*, in *Phyſics*, ſomething that occaſions cold. Some philoſophers, particularly Gaſſendus, and other corpuſcularians, denying cold to be a mere privation, or abſence of heat, contend that there are actual frigorific corpuſcles, or particles, as well as fiery ones: whence proceed *cold* and *heat*; which ſee. See alſo CONGELATION, FREEZING, and FREEZING *Mixtures*.

FRIKEN, in *Geography*, a lake of Sweden, in Warmeland, 40 miles in length, but narrow.

FRILL, in *Falconry*; when a hawk trembles or ſhivers, they ſay ſhe frills. Dict. Ruſt.

FRILLENDORF, in *Geography*, a town of Germany, in the county of Ziegenhayn; five miles N.N.E. of Ziegenhayn.

FRIM, in *Agriculture*, a term employed to denote any ſort of plant which is full of juice. It is often applied to graſs and grain while young, and in a tender ſtate of growth.

FRINGE OF MOSSES, *Periſtomium*, in *Botany*, a ſimple or double row of ſeparate or connected teeth, which border the orifice of the capſule in almoſt all the genera of Moſſes, and are originally covered by the lid and veil. When thoſe parts are fallen, the fringe becomes conſpicuous. It is a very ſenſible hygrometer, for the moſt part expanding by drought, to allow of the diſcharge of the ſeeds. Sometimes however the fringe is expanded by moiſture, and folds together in a dry ſtate of the atmoſphere. The outer fringe, which is in many caſes the only one, is of a much firmer texture, and more deeply coloured, than the inner. It conſiſts either of 4, 8, 16, or 32 teeth, which numbers are as conſtant and invariable in all caſes, as in any other inſtance in natural hiſtory, and far more ſo than thoſe numerical differences in general by which the characters of more ſplendid flowers and fruits are defined. The inner fringe is moſtly a fine plaited membrane, entire at the baſe, but variouſly toothed, jagged, or perforated in the upper part. Sometimes however the inner fringe conſiſts of ſeparate teeth like the outer, only much more delicate. All the parts in queſtion are, in ſeveral inſtances, very brittle and fugacious, but in general they are tolerably durable.

The celebrated Hedwig firſt ſuggeſted the ingenious and fortunate idea of making the fringe of moſſes ſubſervient to the purpoſes of generic diſcrimination. This conſtitutes the chief merit of his ſyſtem, which we ſhall more fully explain when we come to treat of the natural order of MOSSES. At preſent we ſhall deſcribe the ſtructure of the fringe in each genus.

Phaſcum, *Sphagnum*, *Gymnoſtomum*, and *Aniſtangium*, have no fringe at all. In the firſt the lid is of one piece with the capſule, and only ruptured irregularly at one ſide; in the three others the lid ſeparates and falls off entire, leaving the margin of the capſule quite naked and beardleſs.—Theſe genera are diſtinguiſhed from each other by marks derived from other parts of the fructification.

We ſhall now firſt enumerate ſuch genera as are furniſhed with a ſimple fringe.

1. *Tetraphis*. Fringe of four teeth. Theſe are erect, acute, firm, poliſhed and permanent. Mr. Dickſon firſt pointed out to us this ſingularity of ſtructure in the Linnæan *Mnium pellucidum*, long before the publication of Hedwig's diſcoveries. *Botany.—Plate Fringes, fig.* 1.

2. *Octoblepharum*. Fringe of eight teeth. Capſule without an apophyſis. *Bryum albidum* of Linnæus, an Indian plant.—*Fig.* 2.

3. *Splachnum*. Fringe of 16 teeth, dilated at the baſe, approaching each other in pairs. Capſule cylindrical, ſtanding on a fleſhy baſe, or *apophyſis*.—*Fig.* 3.

4. *Encalypta*. Fringe of 16 linear upright teeth. Veil ample, bell-ſhaped.—*Fig.* 4.

5. *Pterogonium*. Fringe of 16 linear upright teeth. Capſule from a lateral ſheath.—*Fig.* 5.

6. *Grimmia*. Fringe of 16 equi-diſtant teeth, dilated at the baſe. Veil cylindrical.—*Fig.* 6.

7. *Conoſtomum*. Swartz in Schrad. N. Tourn. v. 1. faſc. 3. 24. t. 5, 6. Fringe of 16 tapering teeth, approaching each other in pairs, and all cohering at the points. —*Fig.* 7.

This genus is founded by Dr. Swartz on the *Bryum tetragonum* of Dickſon, (*Grimmia conoſtoma*; Engl. Bot. t. 1135. Fl. Brit. 1196), and another ſpecies gathered by Mr. Menzies in Staten-land. They are very much alike, and have the habit, as well as the globoſe furrowed capſule, of a *Bartramia*; but the fringe is totally different. We cannot but confeſs however that the part in queſtion offers conſiderable violence to nature, in obliging us to ſeparate theſe two plants from *Bartramia*.

8. *Dicranum*. Fringe of 16 flat, ſomewhat inflexed teeth, cloven half way down.—*Fig.* 8.

There is no natural difference of habit between this genus and *Grimmia*.

9. *Trichoſtomum*. Fringe of 32 linear ſtraightiſh teeth, approaching

approaching each other in pairs, ſometimes joined in pairs at the baſe.—*Fig.* 9.

10. *Tortula.* Fringe of numerous linear teeth, ſpirally and repeatedly twiſted together.—*Fig.* 10.

In ſome ſpecies of *Tortula* the teeth are united into a cylinder at the baſe, pierced with numerous holes, upon which ſome recent botaniſts have founded a new genus, called *Syntrichium*; but it ſeems ſcarcely neceſſary, nor even allowable. See *fig.* 11.

The following genera are furniſhed with a double fringe, ſome few ſpecies of *Orthotrichum*, and one of the *Buxbaumiæ* perhaps excepted.

11. *Orthotrichum.* Capſule terminal. Outer fringe of 16 teeth; inner of 8 or 16 linear ones, ſometimes altogether deficient. *Veil* furrowed.

This, though a very natural genus, is variable in its fringe, which differs in different ſpecies otherwiſe nearly akin, but it is the only one ſo circumſtanced. *O. pumilum* has but eight teeth in the outer fringe.—*Fig.* 12.

12. *Neckera.* Capſule from a lateral ſcaly ſheath. Outer fringe of 16 teeth; inner of 16 capillary ones. Veil naked and even.—*Fig.* 13.

13. *Funaria.* Capſule obovate. Outer fringe of 16 oblique teeth, cohering at the points; inner of 16 flat teeth. Veil quadrangular.—*Fig.* 14.

14. *Buxbaumia.* Capſule oblique, gibbous on one ſide. Outer fringe of 16 very ſhort teeth; inner membranous, plaited.—*Fig.* 15.

In *B. foliosa* the outer fringe is ſcarcely perceptible. See *fig.* 16.

15. *Bartramia.* Capſule ſpherical, furrowed. Outer fringe of 16 awl-ſhaped teeth; inner membranous, laciniated. Lid depreſſed.—*Fig.* 17.

16. *Mnium.* Capſule terminal, cylindrical, furrowed. Outer fringe of 16 awl-ſhaped teeth; inner membranous, laciniated.—*Fig.* 18.

17. *Bryum.* Capſule ovate-oblong, ſmooth. Outer fringe of 16 teeth, dilated at the baſe; inner membranous, toothed. Flowers terminal.—*Fig.* 19.

18. *Hypnum.* Capſule ovate-oblong, from a lateral ſcaly ſheath. Outer fringe of 16 teeth, dilated at the baſe; inner membranous, variouſly toothed. Veil ſmooth.—*Fig.* 20.

In theſe four laſt genera the fringes do not ſerve us much, the outer one being preciſely alike in all, and the inner one, though different in the number and ſhape of its ſegments in various ſpecies, rather tending by that means to perplex the ſubject, by leading to unnatural combinations. This is the weakeſt part of the ſyſtem of Hedwig, and of thoſe who follow him in making his rules abſolute, without regard to natural affinity. Thus out of *Hypnum*, whoſe inner fringe, for the moſt part, has 16 principal teeth, with ſingle or double intermediate ones beſides, is taken a genus named *Leſkea*, in which there is only a ſimple row of 16 teeth to the inner fringe. This might be allowed, were there any differences of habit or other characters to ſupport the meaſure, but, on the contrary, it ſeparates ſpecies cloſely akin, and ſerves only to divide a moſt natural genus, by a very obſcure and difficult character. Weber and Mohr, in their Swediſh Tour, ſuggeſt another genus founded on *Hypnum dendroides* only, the character of which depends on the inner fringe having 32 teeth, approaching each other in pairs, and moreover meeting by tranſverſe bars, ſo as to imitate bladders, joined at the ſummits. It is named *Climacium*, from κλιμαξ, a ſcale. Whoever is converſant with the varieties of ſtructure in different ſpecies of *Hypnum*, will at once perceive the futility of ſuch generic diſtinctions, in which great pains are taken to render the ſcience not only difficult but unnatural.

19. *Fontinalis.* Capſule enveloped in a lateral ſcaly ſheath. Outer fringe of 16 teeth, dilated at the baſe; inner reticulated.—*Fig.* 21.

Here the inner fringe comes in aid of the generic character in the happieſt manner, being altogether peculiar, and unlike that of any other moſs. It conſiſts of a latticed cone, uſually, if not invariably, of a fine red colour.

20. *Polytrichum.* Outer fringe of 32 or 64 ſhort, flat, inflexed, teeth; inner a tranſverſe orbicular membrane, affixed to the teeth of the outer. Veil moſtly double; the outer hairy.—*Fig.* 22.

Mr. I. D. Sowerby has firſt noticed a ſhort entire membrane, in the mouth of the capſule of this genus, which we are much inclined to think, with him, is the real inner fringe, that above deſcribed being merely the membranous lining of the lid. See *fig.* 23.

We forbear to conſider the whole ſubject of the generic diſtinctions of Moſſes, till we come to them in their proper place, in treating of this natural order. *Andræa* is left out of the above enumeration of genera furniſhed with a fringe, becauſe the recent obſervations of Mr. W. J. Hooker, communicated to the Linnæan Society, prove it to have a capſule of four valves, and no real fringe, thoſe valves having been erroneouſly taken for one of four teeth. S.

FRINGE-*tree*. See CHIONANTHUS.

FRINGE-*tree*, in *Gardening*, a tree of the ornamental kind. See CHIONANTHUS.

FRINGILLA, in *Ornithology*, a genus of paſſeres, the character of which conſiſts ſimply in the form of the bill, which is conic, ſtraight, and pointed. The ſpecies of the fringilla or finch tribe are rather numerous, amounting altogether to about one hundred, independently of many varieties. The finches are in general birds of ſmall or rather moderate ſize, and no very inconſiderable portion of them are excluſively natives of extra-European climates. Some are in particular remarkable for the ſplendour of their plumage.

Species.

LAPPONICA. Head black; body grey and black; eyebrows white; outer tail-feathers with a white wedge-formed ſpot. Linn. *Fringilla Montana*, Briſſ. *Le grand Montan*, Buff. *Greater brambling*, Albin. *Lapland finch*, Arct. Zool.

Native of the Northern parts of Europe and America. The ſpecies aſſociates in ſmall flocks, runs on the ground like the lark, and has a note reſembling that of the linnet. In America it is obſerved to be very partial to the juniper. The female lays five or ſix eggs, of a browniſh ſlate colour; the neſt is compoſed of moſs and graſs lined with feathers.

NIVALIS. Black, beneath ſnowy; ſecondary quill and tail-feathers white. Linn. *Pinçon de neige, ou nouverolle*, Buff. *Snow-finch*, Lath.

Length ſeven inches, with the bill black; head and neck above cinereous; back and rump grey-brown; two middle tail-feathers black, the lateral ones white tipped with black. This ſpecies inhabits Europe, and is alſo a native of part of Aſia. Pallas deſcribes a variety found about the nowy ſummits of the Caucaſian mountains, in which the flanks are ſtreaked with black; and the two outer-moſt tail-feathers marked with a white wedge-formed ſpot.

CASPA. Reddiſh-grey; face and chin white; wing and tail black, the latter forked. Gmel. *Le Dattier*, Buff. *Caſpa ſparrow*, Shaw's Travels. *Caſpa finch*, Lath.

A gregarious ſpecies diſtinguiſhed for its fine note; this bird

bird inhabits Barbary and Abyſſinia, where it is as common near granaries as the common ſparrow in Britain; it feeds on the date as well as grain.

ELEGANS. Above green, with cinereous collar; breaſt yellow; frontlet, throat, rump, and tail red; abdomen with white lunate ſpots. Gmel. *Le beau marquet*, Buff. *Beautiful finch*, Lath.

Length five inches, and in bulk reſembling the common ſparrow; the bill and legs are red; rump and tail cheſnut-red. Inhabits Africa.

FORMOSA. Green; chin and throat yellowiſh; belly barred with black and white; bill and legs red. Lath. *Lovely finch.*

Native of India, and perhaps differing only in ſex from the former.

NOCTIS. Black; chin and lores rufous; bill black. Linn. *Paſſer niger*, Briſſ. *Yohualtototl*, Ray. *Pere noir*, Buff. *Rufous-chinned finch*, Lath.

Size of a ſparrow, with the legs black, and the irides red; the ſpecies inhabits South America, and the American iſlands.

ARCUATA. Cheſnut, beneath white; head and lower part of the neck black; collar and ſtripe behind the eyes white. Gmel. *Moineau du Cap de Bonne Eſperance*, Buff. *Creſcent finch*, Lath.

Native of the Cape of Good Hope; the length of this bird is ſix inches; the leſſer wing-coverts are bay, middle ones white at the tip; quill and tail-feathers brown.

NITENS. Steel-blue black; bill and legs fleſh-colour. Gmel. *Paſſer niger erythrorynchos*, Briſſ. *Paſſer indicus brachyurus*, Ray. *Moineau du Breſil*, Buff. *Short-tailed Indian ſparrow*, Will. *Gloſſy finch*, Lath.

Rather ſmaller than the ſparrow; the bill fleſh-colour, and the irides white. A variety of this ſpecies inhabits Carthagena, in South America, the plumage of which is entirely black; the legs and bill duſky. The Nootka finch, which is totally black, with a white bill, is ſuppoſed to be likewiſe a variety.

LEUCURA. Yellowiſh, ſpotted with cheſnut, and varied with white lines; beneath and head whitiſh-yellow; tail-feathers whitiſh-aſh. Gmel. *Paſſer albicilla bononienſis*, Briſſ. *White-tailed ſparrow*, Aldr.

Inhabits Italy, about Bologna.

BRACHYURA. Entirely yellowiſh. Gmel. *Paſſerculus bononienſis*, Briſſ. *Paſſer brachyurus noſtras*, Ray. *Short-tailed ſparrow*, Will.

The yellow on the breaſt and belly paler than the reſt of the body. The ſpecies inhabits with the former.

CANA. Above yellow-brown, beneath yellow; head and chin grey; vent white; wings and tail brown with white lines, Gmel. *Serinus jamaicenſis*, Briſſ. *Serino affinis e cinereo, luteo et fuſco varius*, Ray. *Grey-headed finch*, Lath.

Length eight inches; legs blueiſh, claws brown, ſhort, and hooked.—Inhabits America.

DALMATICA. Above reddiſh, beneath whitiſh; tail forked. Gmel. *Paſſer Sclavonicus*, Briſſ. *Dalmatic ſparrow*, Will.

Larger than the houſe ſparrow, and inhabits Dalmatia.

BENGALUS. Pale blue; head and back grey; ſides of the head purple. Gmel. *Bengali*, Buff. *Blue-bellied finch*, Lath.

Native of Angola and Bengal. The length is four inches and three quarters; the bill dirty fleſh-colour; quill-feathers brown edged with grey; tail pale blue, a little cuneate; legs white. The female is deſtitute of the purple on the ſides of the head, conſpicuous in the male.

FLAMMEA. Fuſcous; creſt flame-coloured; body beneath roſy. Linn. *Fringilla criſtata*, Briſſ. *Flaming finch*, Arct. Zool. *Crimſon-crowned finch*, Lath.

Size of the red-pole; the bill pale brown; the whole of the top of the head deep flame-colour, inclining to crimſon, and the legs pale brown.

Deſcribed by Linnæus from the paintings of Rudbeck, as a native of Norland, and ſuppoſed to be peculiar to Northern regions.

ILIACA. Cinereous olive; feathers of the upper part of the body ſteel-blue, at the baſe; in the middle olive, with the tip brown; beneath white; tail-feathers and coverts above rufous. Gmel., &c.

Size of a thruſh. This ſpecies inhabits South America.

FLAVIROSTRIS. Brown; bill yellowiſh; feathers on the breaſt roſy at the tips. Linn. *Fringilla fuſca*, Briſſ. *Le Pinçon brun*, Buff. *Arctic finch*, Arct. Zool.

A migratory ſpecies found in Norway and Sweden.

MONTIFRINGILLA. Baſe of the wings beneath fine yellow. Gmel. *Fringuello montanino*, Olin. *Pinſon d'Ardenne*, Buff. *Bramble, brambling, bramble-finch*, Will. Ray, &c.

Length ſix inches and a half, and inhabits Europe and Siberia, where it frequents woods, and feeds on the maſt of beech and other trees. In the male, the head, neck and back are black, in the female brown; the throat and breaſt of the male are tawny, inclining to reddiſh; in the female reddiſh-grey; the quill-feathers are black, edged with yellow; tail ſlightly forked, and the legs grey. One variety of this bird has the eye-brows and band on the nape black; body beneath, and rump white; chin and breaſt red; wing-coverts with a whitiſh band. Another is diſtinguiſhed by the paler colour of the plumage, and in having the head white.

DOMESTICA. Quill and tail-feathers brown; body grey and black; wings with a ſingle white band. Linn. Fn. Suec. *Paſſer domeſticus*, Geſn. *Paſſera noſtrale*, Ol. *Moineau franc*, Buff. *Houſe-ſparrow*, Donov. Brit. Birds, &c.

This well known ſpecies is a general inhabitant of Europe, Africa, and Aſia, and from the boldneſs and familiarity of its habits is moſt abundant in the vicinity of populous places. It builds under the eaves of thatched houſes, and in other ſimilar ſituations; feeds on ſeeds and fruits, and alſo on inſects, and lays about five or ſix eggs, the colour of which is pale-aſh with ſpots of brown.

The principal varieties of this bird are 1ſt, white; 2d, yellow, clouded above with cheſnut; 3d, with the plumage blackiſh. The colours of the female are more obſcure than thoſe of the male.

CRISTATA. Cheſnut, beneath red; crown creſted and red; temples black. Gmel. *Friquet huppé, et Moineau de Cayenne*, Buff. *Black-faced finch*, Arct. Zool.

Size of the common ſparrow, with the bill red, and legs brown. The upper part of the plumage, wings, and tail reddiſh brown; rump crimſon; ſides of the head under the creſt black. This bird inhabits Cayenne.

CAROLINENSIS. Reddiſh brown; belly white; face and pectoral band black; throat and rump ſcarlet. Lath. *Le Moineau de la Caroline*, Buff. *Carolina black-faced finch.*

Native of Carolina, and from its cloſe affinity to the preceding has been conſidered as the female of that ſpecies by ſome writers. Its ſize is rather inferior, the ſpecies criſtata being ſix inches and an half in length, the latter only five inches and an half.

PETRONIA. Grey; eye-brows white; chin pale yellow.

Linn. *Paſſer torquatus*, Ray. *Paſſer ſylveſtris*, Briſſ. *La ſoulcie*, Buff. *Ring-ſparrow*, Will.

Length five inches and a half; feeds on fruits, ſeeds, and inſects. This ſpecies inhabits the ſouth of Europe. It frequents woods, builds in cavities in the trunks of trees, and lays four or five eggs. The red-headed ſparrow of Albin, and the bird called by Briſſon Paſſer torquatus, are ſuppoſed to be two varieties of F. petronia.

STULTA. Reddiſh-grey ſpotted with ferruginous, beneath yellowiſh; wings with a double white band. Lath. *Paſſer ſtultus*, Briſſ. *Paſſer mattugia*, Olin. *Fooliſh ſparrow*, Will.

Inhabits Italy. Size of the houſe-ſparrow.

BONONIENSIS. Spotted with white, black, and yellow, beneath yellowiſh white; head white, with pale yellow ſpots; tail-feathers pale yellow. Lath. *Paſſer maculatus*, Ray. *Speckled ſparrow*, Will.

Size of the former, and an inhabitant of the ſame country.

CÆLEBS. Limbs black; quill-feathers white on both ſides, the three firſt without ſpots; two of the middle tail-feathers obliquely white. Linn. Fn. Suec. *Fringilla ſylvia*, Scop. *Fringuello*, Olin. *Pinſon*, Buff. *Chaffinch*, Donov. Brit. Birds, &c.

A ſpecies found throughout Europe, in ſome parts of Aſia, and on the coaſts of Africa. The chaffinch is a conſtant inhabitant of the Britiſh iſles, being ſeen at all ſeaſons, and is one of the moſt frequent, as well as beautiful of our feathered tribe. In Sweden and Holland the ſpecies muſt be conſidered of the migratory kind, though it is not unworthy of remark that the females only leave thoſe countries, their males remaining behind. This ſingular migration, which is not entirely peculiar to the chaffinch, takes place in autumn, and at a ſtated period in the enſuing ſpring they conſtantly return to their former haunts.

The chaffinch is eſteemed a bird of ſong; its note is pleaſing, but does not continue throughout the whole year. It builds in low and thickſet buſhes. The neſt is compoſed of the fibres of plants and moſs, with a lining of hair, wool, and feathers. The eggs amount to five or ſix, and are of a pale reddiſh grey, with black ſpots at the larger end. The male is diſtinguiſhed from the female by the ſuperior beauty of its plumage, as well as by having the breaſt and other parts tinged with red.

There are many varieties of this ſpecies, among the principal of which the following may be ſpecified:

1. *Le Pinçon à ailes et queue noires*, Briſſ.; the plumage of which is aſhy above, beneath fleſh-colour; wing-coverts white, in the middle black, with the wings and tail black.

2. *Le pinçon blanc*. Entirely white.

3. *Le pinçon à collier*. Like the common kind, except that the collar and crown are white.

4. *Fringilla anterius alba, poſterius ferruginea*, Gmel. The fore-part white; hind-part ferruginous.

5. *Fringilla ſubtus pallidiſſima, dorſo flavicante*, Gmel. Beneath very pale; back yellowiſh.

MEXICANA. Greeniſh-brown, beneath whitiſh. Gmel. *Ligurinus mexicanus*, Briſſ. *Acatechichictli*, Ray. *Mexican ſiſkin*, Lath.

Size of the laſt; this ſpecies is a native of Mexico, and inhabits among reeds.

CACATOTOTL. Blackiſh and fulvous varied; beneath white. Gmel. *Ligurinus mexicanus niger*, Briſſ. *Cacatototl*, Ray. *Black Mexican ſiſkin*, Lath.

Inhabits Mexico.

SERINUS. Somewhat greeniſh; lower mandible whitiſh; back and ſides ſpotted with fuſcous; band on the wing yellow. Linn. *Serinus*, Briſſ. *Serin*, Buff. *Loxia ſerinus*, Scop. *Serin finch*, Lath.

A gregarious ſpecies found in the ſouth of Europe, where it is not uncommon.

FLAVEOLA. Yellow; back greeniſh; front fulvous; quill and tail-feathers black, ſpotted with yellow. Linn. *Saffron-fronted finch*, Lath.

Size of a canary bird, and conjectured to be a mongrel kind produced between the canary bird and goldfinch. The bill is convex, and of a pale colour, with the tip brown; the tail forked and the legs pale. Native place unknown.

AUTUMNALIS. Greeniſh; cap ferruginous; vent teſtaceous. Linn. *Autumnal finch*, Lath.

Native of Surinam.

LEPIDA. Greeniſh fuſcous; band above and beneath the eyes, with the chin orange; breaſt black. Linn. *Lepid finch*, Lath.

Inhabits woods in the Havannah.

BUTYRACEA. Greeniſh; eye-brows, breaſt, and abdomen yellow; primary quill-feathers white at the outer margin. Linn. *Chloris indica*, Briſſ. *Indian green-finch*, Edwards. *Yellow-finch*, Lath.

Native of Madeira, India, and the Cape of Good Hope.

BICOLOR. Head and breaſt black; back, wings, and tail dull greeniſh. Linn. *Chloris bahamenſis*, Briſſ. *Le verdinere*, Buff. *Bahama finch*, Arct. Zool.

A variable ſpecies common in the woods of Bahama. In ſize it agrees with the canary bird. The note is melodious.

BARBATA. Pale yellow; wings green, ſpotted with black and red; chin bearded. Molin. Chili.

According to Molina this ſpecies inhabits the mountainous parts of Chili, and deſcends into the plains in winter; it is eaſily tamed, ſings extremely well, and builds in trees. Its ſize is that of the canary bird. The female is without beard, of a cinereous colour, and has the wings marked with a few yellow ſpots.

AMANDAVA. Fuſcous and reddiſh, with white ſpots; tail-feathers black, with a white dot at the tip. Linn. *Fringilla rubra minima*, Klein. *Bengalus punctulatus*, Briſſ. *Le Bengali piqueté*, Buff. *Amaduvade finch*, Will.

This pretty ſpecies is the ſize of a wren. The female differs in having a mixture of white on the throat and fore-part of the neck, and the belly of a pale yellow colour. It inhabits Bengal, Java, and other parts of Aſia. There is a variety of this bird of a brown colour, in which the wings are marked with only a few white ſpots, and another without any ſpots.

SENEGALA. Ferruginous brown; beneath and crown rufous; bill red, ſtreaked with black. Gmel. *Senegalus ruber*, Briſſ. *Senegal finch*, Lath.

Rather larger than the wren, with tail black, and legs pale grey. It is a native of Senegal, and ſubſiſts chiefly on millet-ſeed; the males ſing well, and the ſong of the females is little inferior to that of the males. The ſpecies bears the climate of Europe extremely well. A ſuppoſed variety of this bird is found in Abyſſinia, the bill of which is purple inſtead of red; the neck and wing-coverts rufous, ſides of the breaſt and wings above ſpotted with white. The female of the latter is entirely brown.

LEUCOTIS. Above duſky, beneath yellow; ears with a white ſpot; primary quill-feathers blue, ſecondary green. Gmel. *White-eared finch*, Oſbeck.

Oſbeck deſcribes, on the authority of ſome Chineſe drawings, ſix analogous kinds of the finch tribe, all which poſſeſs the diſtinctive white ſpot under the ear, which is ſuppoſed

to

to conſtitute a material character of the ſpecies; and hence it is concluded they muſt be varieties of each other. One of theſe has the back and tail purple; another the head green, with the breaſt and tail purple; a third the head, back, and wing-coverts purple, and the tail blue; the head and leſſer wing-coverts are brown, and the breaſt pale green in the fourth; and the fifth is red beneath, with the head, back, tail, and wing-coverts brown; the lower ones ſcarlet. Theſe, with the variety firſt deſcribed, are the ſix mentioned by Oſbeck; they are ſmall, and inhabit China.

ALARIO. Head, collar, and breaſt deep black; body cheſnut, beneath white; four extreme tail-feathers marked with a black line near the tip. Linn. *Paſſerculus capitis bonæ ſpei*, Briſſ. *Cape finch*, Lath.

Size of the common ſparrow, and in length four inches and a half. This is a native of the Cape of Good Hope.

MAIA. Purpliſh, with a purple cheſnut band on the breaſt. Linn. *Cuba finch*, Lath.

The length of this bird is three inches and three quarters. The female is fulvous above, beneath yellowiſh, and the bill whitiſh inſtead of grey, as in the male. In the iſland of Cuba, the native place of this ſpecies, the inhabitants call it Maia. It is a gregarious kind, flies in innumerable flocks, and is extremely deſtructive to the rice plantations, as beſides inſects, the rice conſtitutes its principal food. The fleſh of the Maia is eſteemed delicious.

GRANATINA. Tail wedge-form; body reddiſh brown; bill red; temples, rump, and abdomen violet. Linn. *Braſilian finch*, Edwards.

Theſe birds vary in colour, and in being more or leſs ſpotted with brown; beſides which, there are three or more diſtinct varieties, one having the lores fuſcous, and the hind part of the body violet; another the lower part of the belly and thighs the ſame colour as the body; and a third with the thighs grey-brown; beneath pale tawny, and crown the ſame. Birds of this kind with the tail of a reddiſh colour are alſo ſometimes met with.

The bill of the female, like that of the male, is red; the ſpace beneath the eyes rather purple, the top of the head fulvous; back grey-brown; throat and under parts pale fulvous; and lower part of the belly and vent whitiſh. This is a beautiful ſpecies, of a lively diſpoſition, and has an agreeable ſong. For the latter reaſon it is not unfrequently kept in cages by the Europeans in the Braſils.

FUSICOLLIS. Crown, rump, and vent green; back ferruginous; throat browniſh, with a cinereous and reddiſh ſpot; tail half yellow, half black. Gmel. *Brown-throated finch*, Lath.

Bill red; legs yellow; behind the eyes a white line. This ſpecies inhabits China, and is of a ſmall ſize.

ZEYLONICA. Yellow; back greeniſh; head black; body beneath white, and blackiſh varied; quill and tail-feathers blackiſh. Gmel. *Ceylon finch*.

A ſpecies of ſmall ſize inhabits China, and alſo Ceylon; there is a variety of this bird, the back of which is green; breaſt and belly yellowiſh white, and the head brown-red.

IGNITA. Shining fuſcous red; wings and cuneated tail black. Gmel. *Fire-finch*, Brown.

Inhabits Africa. The ſize is that of the linnet, and the female is browniſh, with the front and lores red, and the tail reddiſh with the tip duſky.

TRICOLOR. Black, head and rump blue; ſhoulders green; abdomen yellowiſh. Linn. *American ſparrow of Seba*, Bancroft. *Blue-faced finch*.

Native of Surinam.

CYANOCEPHALA. Red-brown; crown and rump blue; beneath yellow; nape red, orbits white. Gmel. *Blue-crowned finch*, Lath.

Length ſeven inches. This inhabits Senegal.

CYANOMELAS. Blue; frontal line, chin, and dorſal lunule black; quill-feathers fuſcous; tail blackiſh. Gmel. *Demi-fin noir et bleu*, Buff. *Blue-headed finch*, Lath.

Size of the greater linnet; the bill brown, and legs black. Native place not aſcertained.

DIUCA. Azure; throat white. Molina.

Inhabits Chili.

ULTRAMARINA. Entirely deep azure; bill white; legs red. Gmel. *L'Outre-mer*, Buff. *Ultramarine finch*, Lath.

Native of Abyſſinia; female and young grey.

ABYSSINICA. Yellow; beneath, and collar black; wings and tail black with yellowiſh margins. Gmel. *Le Worabé*, Buff. *Black-collared finch*, Lath.

Size of the canary bird, gregarious, and inhabits Abyſſinia.

SYRIACA. Fuſcous, blackiſh and yellow varied; beneath whitiſh with duſky ſpots; crown red. Gmel. *L'Habeſch de Syrie*, Buff. *Tripoline finch*, Lath.

Rather leſs than the linnet. This ſpecies inhabits Syria, and is migratory.

ATRA. Blackiſh, breaſt and rump pale aſh. Gmel. *Fringilla obſcura*, Lath. Ind. Orn. *La Linotte brune*, Buff. *Duſky finch*, Edwards.

Length four inches, the bill aſh colour, legs duſky, and the feathers throughout paleſt at the tips. The ſpecies is ſuppoſed to inhabit Angola.

ANGOLENSIS. Browniſh-aſh, with fuſcous ſpots, beneath cheſnut; frontlet and chin black; cheeks and throat ſpotted with white; rump pale yellow. Gmel. *Lniaria Angolenſis*, Briſſ. *Vengoline*, Buff. *Angola finch*, Lath.

Size of the common linnet; the bill brown, and the legs fleſh colour; the upper part of the plumage in the female is reddiſh brown, beneath reddiſh, with a fuſcous band extending from the baſe of the bill to the back part of the head. In Angola the male is called by the natives Negral, and the female Benguelinha. The ſpecies is remarkable for its melodious ſong, which is even ſaid to ſurpaſs that of any other extra-European bird, the American mocking-bird excepted.

BENGALUS. Pale azure; head and back grey; ſides of the head purple. Linn. *Fringilla Benghalus*, Lath. Ind. Orn. *Le Bengali*, Buff. *Blue-bellied finch*, Edwards.

The female differs from the male in wanting the red ſpot beneath the eyes, in other reſpects they nearly agree. The ſpecies inhabits Bengal and alſo Angola. Its length is about four inches and a half; the bill dirty fleſh-colour; quill-feathers brown edged with grey; tail pale blue, rather wedge-form and the legs whitiſh. There is a variety of this ſpecies with the back brown, and the belly and tail blue.

CARDUELIS. Quill-feathers black, in the middle yellow, with the two outer black; two extreme tail-feathers white in the middle, the reſt white at the tips. Linn. Fn. Suec. *Carduelis*, Geſner. *Cardello*, Olina. *Chardonneret*, Buff. *Goldfinch, or thiſtle-finch*, Will. Albin. Donov. Brit. Birds.

The goldfinch is a general inhabitant of Europe, and a conſiderable part of Aſia and Africa, and a variety of it at leaſt is found even in the American iſlands. This beautiful and well known ſpecies conſtructs its neſt of fine moſs intermingled with lichens, the down of thiſtles and other plants, and lines the interior with hair and wool; the eggs are five in number, of a white colour, marked with deep purple at the larger end. It often builds in orchards, and has com-

monly two broods in a year. The goldfinch is obſerved to abound moſt in thoſe places where thiſtles occur in the greateſt plenty, and hence it was called by early Engliſh writers the thiſtle finch. The ſeeds of the thiſtle is a favourite food with this bird; it will alſo feed on hemp and other ſeeds as well as fruit and inſects. The ſpecies is remarkable for the docility of its diſpoſition, and as it ſings charmingly, it is frequently kept in cages. The male differs from the female chiefly in the ſuperior ſtrength and beauty of its colours. The varieties of the goldfinch are altogether numerous, among which the following are conſidered the moſt permanent.

1. *Carduelis leucocephalos*, Briſſ. *Chardonneret à tête blanche*, Buff. *White-headed goldfinch*, Will. In this the region of the bill and eyes are ſnowy.

2. *Carduelis capite ſtriato*, Briſſ. *Chardonneret à tête rayée*, Buff. *Goldfinch*, Brown, Jamaica. Having the head ſtreaked with red or yellow.

3. *Carduelis melanocephalos*, Briſſ. *Chardonneret à tête noire*, Buff. The head black; ſometimes the neck of this kind is alſo black, and the bill ſpotted at the baſe with red.

4. *Carduelis albida*, Briſſ. *Chardonneret blanchâtre*, Buff. *Whitiſh goldfinch*, Will. A variety of a whitiſh colour, with the front, cheeks, and chin red; and the wings and tail browniſh-aſh.

5. *Carduelis nigra*, Briſſ. *Chardonneret noir*, Buff. Entirely black.

The plumage of the goldfinch, like that of the lark and ſome other ſmall birds, becomes black from the bird feeding on hemp ſeed, a fact extremely well authenticated by the experiments of modern ornithologiſts.

6. *Carduelis nigra icterocephalos*, Briſſ. *Carduelis congener*, Ray. *Chardonneret noir à tête jaune*, Buff. *A bird of kin to the goldfinch*, Will. This is rather larger than the common goldfinch; the bill ſurrounded with a ſaffron-coloured ring, the reſt of the head and upper parts dark.

7. *Carduelis hybrida*, Briſſ. *Chardonneret métis*, Buff. *Canary goldfinch*, Albin. Like the former this exceeds the common goldfinch in magnitude; the colours on the head are ſimilar to the ordinary kind, but more obſcure; the upper parts of the body yellowiſh-brown; under parts yellow; wings as in the goldfinch, and the tail yellow with the tip black. This is the hybrid between the goldfinch and canary.

8. *Le Chardonneret blanc*, Briſſ. A variety wholly white. Sometimes the white variety has the outer edge of the quills tinged with yellow, or a little mixture of yellow on the wing-coverts. In others thoſe parts of the plumage which in the common bird are red, exhibit a faint bluſh or tint of that colour; or are more or leſs mottled with red.

Cannabina. Cheſnut-brown, beneath reddiſh-white; wings with a longitudinal white band; ſpot on the crown and breaſt red. Linn. *Linaria marina*, Aldr. *Grande linotte de vignes*, Buff. *Greater red-headed linnet*, Ray. *Greater red-pole*, Arct. Zool.

This pretty bird is an inhabitant of Europe and America; its ſize is rather leſs than that of the common linnet, and its length nearly the ſame. The head of the female is aſh-coloured, ſpotted with black, the back and ſcapulars of a reddiſh-brown, the breaſt and ſides dirty yellow, ſtreaked with duſky lines.

Linaria. Brown, varied with grey; beneath reddiſh-white; wings with a double white band; crown and breaſt red. Gmel. *Leſſer redpole*.

Numerous throughout Europe. The ſize is conſiderably leſs than that of the greater red-pole; the bill and legs brown; the back black; ſides marked with narrow duſky lines, and the legs duſky. The female has a ſpot of ſaffron on the front.

Linota. Cheſnut-brown, beneath whitiſh; wings with a longitudinal white band; tail-feathers each ſide edged with white. Gmel. *Common linnet*.

Size of the laſt. The bill is grey with the tip brown; ſides of the neck cinereous; throat with a brown line in the middle, bounded on each ſide with a white one; bottom of the breaſt blood red; vent yellowiſh, with the two middle tail-feathers edged with red. In the female and young birds the red is wanting on the breaſt. This ſpecies inhabits Europe, and feeds principally on hemp ſeed, which it peels before it eats.

The linnet is common in England, and is often kept in cages, being in high eſteem for the ſweetneſs of its ſong. It alſo breeds in this country. The neſt, which is compoſed of dried herbs, graſs, and moſs, and lined with hair and wool, is uſually built in thickets of black and white thorn, or in a furze buſh. The female lays from four to five white eggs, ſpotted with reddiſh-brown at the larger end. Linnets are frequently found in flocks during winter, and when in want of food will eat any kind of ſeed, though they prefer the hemp ſeed. Linnets are ſometimes met with entirely of a white colour, and there is beſides another variety which has the quills and tail black, edged with white.

Canaria. Bill and body ſtraw-colour; quill and tail-feathers greeniſh. Linn. *Le Serin des Canaries*, Briſſ. *Canary bird*, Will.

In a wild ſtate the canary bird is, as the name implies, an inhabitant of the Canary iſlands; and is alſo found in other places, as Palma, Cape Verd, Fayal, and Madeira, where it frequents watery places, and feeds on ſeeds, eſpecially thoſe of the hemp and canary-graſs. The delightful ſong of the canary bird is familiar to every one. They are caught in vaſt numbers, and tranſported from their native climate to different parts of Europe, where they bear the confinement of the cage remarkably well, and not only thrive, but breed with perfect facility.

The canary bird, beſides becoming productive with its own ſpecies in European climates, will breed pretty freely with the ſiſkin and the goldfinch, and alſo with the linnet, the yellow-hammer, and chaffinch, and even the houſe-ſparrow. The male canary bird will not aſſimilate with the females of thoſe birds, the hen muſt be of the canary kind to produce this union; the young obtained from croſſing the breeds are in general mules, though the contrary does ſometimes happen.

An enumeration of the many varieties of theſe birds that are to be found in a ſtate of domeſtication, would be altogether tedious; we may briefly obſerve that in a ſtate of nature the prevailing colour of the plumage is grey, and that by various means of culture, and pairing them with other ſpecies, the varieties are at leaſt as numerous as thoſe of our common poultry. Buffon particularly deſcribes twenty-nine diſtinct varieties, and there are many others which he has entirely omitted.

It is a long-lived bird, attaining to the age of ten or fifteen years, or, according to Salerne, even as far as eighteen.

Macroura. Body fuſcous, with blackiſh ſpots, beneath pale cinereous, tail wedge-formed and elongated, the two middle tail-feathers narrow, pointed, and greeniſh-brown. Gmel. *Long-tailed finch*, Lath.

From Cayenne. In ſize agrees with the linnet; length ſeven inches and a half, the legs and bill brown.

Argentoratensis. Fuſcous, beneath rufous, ſpotted with

with fuſcous, belly and vent whitiſh. Gmel. *Linaria argentoratenſis*, Briſſ. *Le Gyntel de Straſburg*, Buff. *Straſburgh finch*, Lath.

Size of the common linnet. Inhabits the environs of Straſburgh, where it is called Gyntel. The quills and tail are brown, the legs reddiſh.

CAUDACUTA. Varied with rufous and brown; eye-brows, chin, and neck above rufous; tail entire, the feathers all pointed at the tips. Lath. Ind. Orn.

Inhabits the interior of Georgia in America. The length of this bird is four inches and a half, the bill and legs pale; irides fuſcous.

GEORGIANA. Fuſcous, beneath whitiſh; leſſer wing-coverts entirely, with the edges of the outer webs of the tail-feathers, rufous; chin and throat mouſe-coloured; beneath the arm-pits a black ſtreak. Lath. Ind. Orn.

About ſix inches in length; the bill duſky, irides fuſcous; head fuſcous, the back blackiſh in the middle; legs fuſcous. This ſpecies inhabits the ſame country as the former.

MELANICTERA. Black; abdomen ſpotted with white; wings and tail edged with ferruginous. Gmel. *Moineau de Macao*, Buff. *Black and orange finch*, Lath.

Size of a linnet. The ſpecies inhabits Macao.

MELANOLEUCA. Black, with a white pectoral band. Gmel. *Moineau de Java*, Buff. *White-breaſted finch*, Lath.

Found in Java, and inhabits ſame country as the laſt.

PECORIS. Fuſcous, beneath paler; tail ſomewhat forked. Gmel. *Fringilla virginiana*, Briſſ. *Brunet*, Buff. *Cowpen bird*, Cateſby. *Cowpen finch*, Lath.

Native of Virginia and Carolina. Length ſix inches and three quarters.

JAMAICA. Grey; breaſt blueiſh-green; quill and tail-feathers black. Linn. *Le Bonana*, Buff. *Paſſer cæruleo-fuſcus*, Ray. *Grey groſbeak*, Brown. *Bonana finch*, Lath.

Size of the ſiſkin, with bill and legs black. Native of Jamaica.

CANA. Yellow-brown, beneath pale yellow; head and chin grey; wing and tail-feathers fuſcous, with white lines. Gmel. *Serinus jamaicenſis*, Briſſ. *Grey-headed finch*, Lath.

Inhabits Jamaica. Length eight inches; legs blueiſh.

SAVANNARUM. Above brown, varied with whitiſh and pale yellow; beneath yellowiſh-brown; belly and tip of the quill-feathers white; wings and tail brown; eye-brows yellow. Gmel. *Paſſer jamaicenſis*, Briſſ. *Paſſer pratorum*, Klein. *Savanna bird*, Ray. *Savanna finch*, Lath.

Native of Jamaica. The length of this bird is four inches and a quarter; the bill ſhort, thick, and pointed, and the legs whitiſh. Sloane relates, that "they ſit on the ground in the plains, and run thereon after the manner of ſkylarks, as low as they can to avoid being diſcovered, and when raiſed, fly not far nor high, but light again very near."

COCCINEA. Fulvous ſcarlet; wings and tail black; quill-feathers orange at the outer edge, the primaries black at the tips. Gmel. *Scarlet finch*, Lath.

Length four inches; the bill pointed, and of a pale colour; tail even at the end; legs black.

ROSEA. Roſy; frontlet ſilvery; back with browniſh-grey ſtripes; wings and tail blackiſh; tail-feathers roſy on the outer edge. Gmel. *Fringilla roſea*, Pallas. *Roſy finch*.

A rare ſpecies found among the willows in Siberia. There is a variety of this kind found likewiſe in Siberia, the plumage of which is reddiſh-aſh above, beneath white; the feathers of the head, rump, and throat tipped with fine red; quill and tail-feathers brown, edged with pale yellow. This is the crimſon-crowned finch of the Arctic Zoology. The loxia erythrina of Gmelin is conſidered by Dr. Latham as a variety alſo; its colour is reddiſh cinereous above, beneath white, with the head, rump, chin-feathers red at the tip; lower part of the neck whitiſh; and the tail, which is rather forked, with brown ſhafts, and pale yellow margins. This laſt-mentioned bird inhabits the thick woods about the Volga and Samara, where it is ſaid to breed. The female makes a neſt of hay between the branches of trees.

PUNICEA. Black; cheeks, throat, and breaſt red; wing-coverts with two white lines. Gmel. *Red-breaſted finch*. Arct. Zool.

Native of America.

FERRUGINEA. Fuſcous, with ferruginous margins, beneath pale; breaſts with duſky ſpots; region of the eye white. Gmel. *Little ſparrow*, Edwards. *Ferruginous finch*, Arct. Zool.

Size of the common ſparrow, and inhabits Pennſylvania.

ALBICOLLIS. Cheſnut, beneath hoary; chin white; cheeks hoary; eye-brows orange. Gmel. *Fringilla Penſylvanica*, Lath.

Length ſix inches and a quarter. Inhabits ſame country as the former.

FASCIATA. Spotted, above ferruginous, beneath white; tail fuſcous, with numerous blackiſh bands. Gmel. *Faſciated finch*, Arct. Zool.

Native of New York.

GRAMINEA. Varied with ferruginous, cinereous and black; beneath white; breaſt and ſides ſpotted; throat ſtriated; tail, and primary quill-feathers blackiſh; leſſer wing-coverts bay. Gmel. *Gräſs finch*, Arct. Zool.

Inhabits with the former, and lays its eggs in the graſs.

PINETORUM. Above reddiſh, teſtaceous, beneath yellow; breaſt with a tranſverſe ferruginous band. Lepechin.

A ſpecies found in the pine foreſts of Siberia.

CINEREA. Fuſcous with ferruginous margin; two lateral lines on the head with the chin grey; throat greyiſh; abdomen white in the middle. Gmel. *Cinereous finch*, Arct. Zool.

Native of Aoonalaſhka.

ZENA. Black, beneath white; above and beneath the eye a white line; breaſt orange. Linn. *Fringilla bahamenſis*, Briſſ. *Le Pinçon à tête noir et blanche*, Buff. *Bahama finch*, Cateſby. *Orange finch*, Arct. Zool.

The bill and legs are lead colour; wings and tail brown, and the wing-coverts marked with a white band. The female has the head and neck cinereous. This ſpecies inhabits South America. Its length ſix inches and a quarter.

SYLVATICA. Head banded; body above grey and black varied; breaſt and belly hoary. Lepechin. *Wood-finch*.

Inhabits the pine foreſts of Siberia.

NORTONIENSIS. Black, beneath white; threat ſpotted with ferruginous; quill-feathers and tail black, the outer

feathers

feathers on each ſide the latter with a white longitudinal line. Gmel. *Norton finch*, Arct. Zool.

Found in Norton Sound.

HYEMALIS. Fuſcous, clouded with black, beneath white; lower part of the neck, breaſt, and ſides ſpotted with brown. Gmel. *Winter finch*, Arct. Zool.

Inhabits New York during the winter ſeaſon.

STRIATA. Clouded with fuſcous; head with four black ſtreaks; face yellow; temples whitiſh; wing-coverts and ſub-cuneated tail brown; wings blackiſh. Gmel. *Striped-headed finch*, Arct. Zool.

Inhabits with the laſt, and meaſures in length five inches and a half.

PURPUREA. Sub-violaceous; belly white; quill-feathers brown on the inner webs. Gmel.

Size of the laſt. This kind inhabits Carolina, and feeds on the juniper berries and the buds of fruit-trees. The tail is ſlightly forked, the female fuſcous, and having the belly ſpotted with white.

SURINAMA. Grey; quill-feathers each ſide and lateral tail-feathers within white. Linn. *La linotte de Surinam*, Ferm. *Surinam finch*, Lath.

Native of Surinam. Its ſize rather exceeds that of our common ſparrow, its note is indifferent, but the fleſh is in much eſteem.

LONGIROSTRIS. Grey, varied with brown and yellow; beneath orange; tail olive, head and chin black, with cheſnut collar. Gmel. *Le Pinçon a long bec*, Buff. *Long-billed finch*, Lath.

Remarkable for the length of its bill; the ſpecies is larger than the chaffinch, and inhabits Senegal.

SINICA. Rufous olive, beneath teſtaceous; quill and tail-feathers black, with the baſe pale yellow. Linn. *L'Olivette*, Buff. *Pinçon de la chine*, Pl. Eul. *Chineſe finch*, Lath.

Native of China, and in ſize reſembles the linnet.

SINENSIS. Olive, beneath yellow: head, bill, legs, and quill-feathers black, the greater quill and tail-feathers half yellow. Gmel. *Le Tarrain de la Chine*, Sonnerat. *Chineſe ſiſkin*, Lath. *Fringilla aſiatica*, ibid.

Inhabits with the preceding.

NÆVIA. Cinereous with obſcure ſpots, beneath cinereous; chin white; lores rufous; on the jaw a black ſtreak. Gmel. *White-cheeked finch*, Lath.

Size of the common ſparrow; and is an African ſpecies, found chiefly at the Cape of Good Hope.

MELANOCEPHALA. Ferruginous brown; head, throat and quill-feathers black; nape and abdomen white, with the bill red. Gmel. *Black-headed finch*, Lath.

Native of China.

FUSCA. Brown, with the margins of the feathers blackiſh; beneath brown-white. Gmel. *Brown finch*, Lath.

Inhabits ſame country as the preceding.

EUSTACHII. Yellow, beneath orange; ſpot beneath the eye blue; wings and tail red. Gmel. *Fringilla inſulæ S. Euſtachii*, Briſſ. *Le pinçon jaune et rouge*, Buff. *Paſſer Africanus extimius*, Seba. *Euſtachian finch*, Lath.

Native of the iſland of St. Euſtatia. Length five inches and a half.

VARIEGATA. Red, yellow, blue, and white, varied; breaſt pale-yellow, clouded; tail at the tip and margin white. Gmel. *Le Touite*, Buff. *Variegated finch*, Lath.

Size of the laſt; the bill yellow, and legs red. The ſpecies inhabits New Spain.

CRISPA. Olive, beneath pale yellow; head black; many of the feathers recurvate. Linn. *Le Pinçon friſé*, Buff. *Black and yellow frizzed ſparrow*, Edwards. *Frizzled finch*, Lath.

Inhabits Africa.

INDICA. Cinereous fuſcous, beneath rufous white; frontlet, throat, collar and neck white; pectoral band with the wings and tail black. Gmel. *Fringilla torquata indica*, Briſſ. *Le Pinçon à double collier*, Buff. *Collared finch*, Edwards.

Native of India.

MELBA. Green; face and tail red, abdomen undulated with black and white. Linn. *Carduelis viridis*, Briſſ. *Maracaxao*, Buff. *Green finch*, Edwards.

Size of the goldfinch; the bill is fleſh colour; lores blueiſh; and tail entire. The female is diſtinguiſhed by having the bill pale yellow; top of the head and neck aſh-colour, and the baſe of the wings and rump yellowiſh. Linnæus deſcribes it as a native of China.

AFRA. Fuſcous-green; cheeks pale crimſon; tail ſcarlet; primary quill-feathers duſky, with orange margins. Gmel. *Red-faced finch*, Brown.

Inhabits Angola.

PSITTACEA. Green; face, rump, and tail ſcarlet; inner edge of the quill-feathers brown. Gmel. *Parrot finch*, Lath.

A beautiful ſpecies, rather leſs than the wax-bill; it inhabits New Caledonia.

ERYTHROCEPHALA. Olive; head and collar ſcarlet, with black orbits; wings black with two bars of white on the coverts. Gmel. *Red-headed finch*, Brown.

Inhabits Mauritius.

LULENSIS. Fuſcous; breaſt and ſhoulders rufous; wings black with a rufous ſpot; collar and body beneath white. Linn. *Carduelis ſuecica*, Briſſ. *Le Chardonneret a quatre races*, Buff. *Lulean finch*, Arct. Zool.

Native of Sweden, chiefly about Weſt Bothnia, and in ſize correſponds with the goldfinch.

TRISTIS. Yellow; front black; wings fuſcous. Linn. *Carduelis americana*, Briſſ. *Le Chardonneret jaune*, Buff. *American goldfinch*, Arct. Zool. *Green ſparrow*, Bancroft.

Length four inches and a half, with the bill and legs white, the female duſky and deſtitute of the black on the head. They inhabit New York during the ſummer ſeaſon, and feed on thiſtles. The bird called by Buffon le tarin de la Nouvelle Yorck is ſuppoſed to be a variety of this ſpecies, or the ſame in its winter dreſs.

SPINUS. Quill-feathers pale yellow in the middle, the firſt four without ſpots; tail-feathers yellow at the baſe, and tipped with black. Linn. Fn. Suec. *Acanthus avicula*, Geſner. *Ligurinus*, Briſſ. *Lucarino*, Ol. *Abadavine*, Albin. *Siſkin*, Donov. Br. Birds.

PICTA. Purpliſh; crown, wings, and tail blue; rump yellow; collar, breaſt, and vent red. Gmel. *Azure-headed finch*, Lath.

Deſcribed by Dr. Latham from a Chineſe drawing in the poſſeſſion of Dr. Fothergill. The length is four inches, the bill and legs red, and the greater wing-coverts green.

TORQUATA. Reddiſh; rump blue; lunule on the cheeks black; quill-feathers black with the tips blue, and a white ſpot at the extremity. Gmel. *Lunar finch*, Lath.

Native of India. Length ſix inches.

MULTICOLOR. Black, beneath yellowiſh; vent yellow; cheeks yellowiſh; lower part of the back green; wing-coverts with a white ſpot; ſecondary quill-feathers with white lines near the tip. Gmel. *Green-rumped finch*.

Inhabits Ceylon.

TESTACEA. Teſtaceous brown clouded with black;

quill-feathers and tail fuſcous; bill and legs fleſh colour. Jacquin. *Teſtaceous finch.*

Length five inches and a half, and ſuppoſed to inhabit Luſitania.

FLAVICOLLIS. Cinereous, beneath whitiſh; chin white; throat with a yellowiſh ſpot; primary quill-feathers black, edged with brown; bill and legs blueiſh-grey. Gmel. *Yellow-throated finch*, Arct. Zool.

Native of North America.

CARTHAGINIENSIS. Entirely cinereous with fuſcous and yellow ſpots; bill and legs pale fuſcous. Jacquin. *Carthagena finch.*

Size of the canary bird. The ſpecies inhabits South America, and in ſong reſembles the chaffinch.

OCHRACEA. White; head, ſides of the neck, breaſt, and wing-coverts ochre colour; bill and legs yellow. Jacquin. *Ochre finch.*

Inhabits Auſtria. Size that of the chaffinch.

IMPERIALIS. Ruſty-roſy; crown, and beneath yellow; quill-feathers and tail ſhort and obſcure. Lath. *Imperial finch.*

Size of the Amaduvade; bill and legs fleſh colour; inhabits China.

AUSTRALIS. Fuſcous; collar ferruginous. Lath. *Ruſty collared finch.*

Inhabits the iſle of Terra del Fuego.

FRINGILLAGO, a name by which ſome have called the whole genus of the titmouſe; but others have reſtrained it only to one ſpecies of them, which is the common larger kind, called by us the ox-eye. See PARUS *major.*

FRINGILLAGO *Americana cærulea*, a name given by Mr. Ray to the American titmouſe, otherwiſe known by its Braſilian name *guiragenoia.* See TANAGRU *braſilienſis.*

FRINGILLARIUS, ACCIPITER, the name of a ſpecies of hawk, called by ſome *niſus*, and in Engliſh the ſparrow-hawk. See FALCO *Niſus.*

FRINGYBAZAR, in *Geography*, a town of Hindooſtan; 11 miles S.S.E. of Dacca.

FRINGYPAT, a town of Hindooſtan, in Canara; ſix miles E. of Mangalore.

FRIO, a river of Spain, which riſes in Grenada, and runs into the ſea at Toros.

FRIO, a ſmall iſland on the coaſt of the Brazils, ſituated in S. lat. 32° 2′. and in W. long. 41° 31′ 45″. The land is high, with a hollow in the middle, which makes it appear at a diſtance like two ſeparate iſlands. The paſſage between the iſland and the continent is about a mile broad, and ſeemed to ſir Eraſmus Gower to be clear of ſhoals.

FRIPPERY, a French term, ſometimes uſed in our language; properly importing the trade, or traffick of old ſecond-hand cloaths and goods.

The word is alſo uſed for the place where ſuch ſort of commerce is carried on, and even for the commodities themſelves. The company of Frippiers, or Fripperers, at Paris, form a regular corporation, of an ancient ſtanding, and make a conſiderable figure among the companies of that city.

FRISAWA, in *Geography*, a river of Moravia, which runs into the Marſch, five miles N. of Maglitz.

FRISCH, JOHN LEONARD, in *Biography*, was born at Sulztach, in the Upper Palatinate, in 1666. He ſtudied at various univerſities in Germany, and after travelling through France and Switzerland, he ſucceeded the evangelical preacher, Elias Breithorn, at Newſol in Hungary, but was driven from thence by perſecution, and became an interpreter during the Turkiſh war. From Hungary he went to Venice and other parts of Italy, and was in 1693 appointed ſuperintendant of a nobleman's eſtate near Nuremberg. After this he went firſt to Holland, and then to Berlin, where he was appointed ſub-rector, and then rector of the Grey Convent Gymnaſium in 1726. By the recommendation of the celebrated Leibnitz, whom he inſtructed in the Ruſſian language, he was choſen a member of the Royal Academy of Sciences, and of the Imperial Academy of the Searches into Nature. He had already perpetuated his name by being the founder of the ſilk manufactory at Brandenburg, and he was the firſt perſon who cultivated mulberry-trees in the neighbourhood of Berlin, where he formed a plantation of them, which flouriſhed to a very great degree. He conceived an idea that church-yards, in the city and adjacent villages, might be planted with theſe trees to great advantage, and the plan was recommended in the year 1718 by Frederic William I. He was author of a German dictionary, and wrote a deſcription of all the inſects of Germany, of which thirteen parts were publiſhed. Theſe have been of no ſmall uſe to ſucceeding naturaliſts. He was author of many other works, among theſe was one entitled, "A Repreſentation of the birds of Germany, with a few of foreign countries, coloured after nature." This was finiſhed, and publiſhed by Friſch's ſon, and is eſteemed by naturaliſts on account of the great accuracy of the colouring. It contains twelve grand claſſes, which occupy 255 plates, and 179 pages of deſcription; of theſe Friſch wrote the deſcription of the four firſt claſſes only. Gen. Biog.

FRISCH *Haff*, in *Geography*, a gulf or arm of the ſea, on the coaſt of Pomerania, S. of the Baltic; about 25 miles in length from eaſt to weſt, and eight from north to ſouth. The Oder paſſes through it at its eaſtern extremity.—Alſo, a bay or arm of the ſea, between Konigſberg and Elbing, ſeparated from the Baltic by a tongue of land, called "Friſen Nerung," 26 miles long, and ſcarcely two wide. The bay is about 54 miles in length, and hardly ſix in breadth. It communicates with the Baltic by a narrow paſſage near Pillau.

FRISCHBACH ALLEN, a mountain of Stiria; 10 miles E. of Pruck.

FRISCHLIN, NICODEMUS, in *Biography*, a learned German, was born in the duchy of Wirtemberg in 1547. He was educated partly under his father, and partly at the univerſity of Tubingen, and at the latter place he taught the belles lettres, and other ſubjects relating to polite literature. He profeſſed to teach the principles of grammar in a new and eaſy method, and publiſhed ſtrictures upon former grammarians, in a work entitled "Strigil Grammatica," which involved him in ſome angry controverſies with others of the profeſſion. In a commentary, which he publiſhed on the Bucolics and Georgics of Virgil, he indulged ſuch acrimony of ſtyle in declaiming upon the compariſon between the innocence of a country life, and the corrupt manners of the great, that he was compelled to quit his native country, and wander through the different parts of Germany. At Mentz he wrote to the duke of Wirtemberg for pecuniary aſſiſtance, of which he ſtood in great need, but being diſappointed in his application, he wrote back a remonſtrance ſo full of abuſe, that he was arreſted, and carried to the priſon of Aurach, in the duchy. Attempting to eſcape from this place by cutting his ſheets into ſlips, and thus to let himſelf down from the window, his weight broke the ſupport, and he was unfortunately killed by the fall. This happened in November 1590, when he was forty-three years old. He had a wonderful facility in making verſes, and wrote 16 books of elegies, ſeven comedies, two tragedies, and a multitude of anagrams, odes, &c. From the emperor Rodolph he obtained the golden laurel, and the title of "Crowned Poet."

He

He left commentaries upon the epiſtles of Horace, and the ſatires of Perſius, and tranſlations of Oppian, Ariſtophanes, Callimachus, and Heliodorus. Moreri.

FRISCHLING, in *Geography*, a river of Pruſſia, which riſes about 10 miles N. of Pruiſch Eglau, and runs into the Friſch Haff; two miles S. W. of Brandenburg.

FRISNIK, a town of Moravia, in the circle of Iglau; four miles S.S.E. of Iglau.

FRISONS, or FRISIANS, in *Ancient Geography*, ancient inhabitants of the country which ſtill bears their name; between the Amaſia or Ems, and the Rhine. To the eaſt they had the Chauci, Chamari, and Angrivari, from whom they were ſeparated by the Amaſia; to the weſt, the Rhine; to the ſouth, the Bructeri; and to the north, the ocean. But in the decline of the Roman empire, their name and dominion extended from the Cimbric Cherſoneſus to the Scheldt; their limits being variable according to the circumſtances of the times. They were diſtinguiſhed into the Upper and Lower Friſons; the former being divided, as we have ſaid, from the Lower Chauci by the Amaſia, and from each other they were divided by an arm of the Rhine. Their country ſtill retains the name of Frieſland, and is divided into eaſt and weſt; but the latter has been diſmembered from Germany, and conſtituted one of the ſeven United Provinces. See FRIESLAND.

In order to account for the extenſion of their dominion, it ſhould be recollected, that when the Roman power declined in Gaul and the Barbarians encroached on its limits, the maritime people of Germania Secunda, whoſe fidelity to the Romans had rendered them odious to thoſe nations who inhabited the other ſide of the Rhine, re-united for their defence. With this view they choſe a general, to whom they gave the command of their combined troops, but they maintained their own laws and cuſtoms, and the particular form of their government. The Friſons, being the moſt powerful, gave their own name to this league. In proceſs of time they were joined by the Saxons, who participated of this honour, and the two names were for ſome time ſynonymous. Accordingly, under the appellation of Friſons many people of leſs note, but of appropriate denominations, were comprehended; and this appellation was given to their whole country. The Friſons were ſimple and ingenuous; but eminently courageous; they loved liberty and recurred to arms in order to defend it. So jealous were they of their freedom and independence, that in order to guard againſt the intruſion of ſtrangers, they cauſed them to articulate certain words, peculiar to themſelves; and if they were unable to do this, they were precipitated into the marſhes. The Friſons were for a long time, as it is ſaid, governed by kings. Druſus having paſſed the Rhine, conquered Friſia, and the inhabitants became his allies and reſcued him from danger incurred by his attack on the Cauci. Druſus impoſed upon them an eaſy tribute, which conſiſted merely of ſome ox-hides for the ſoldiers' bucklers and machines of war. This tribute they contentedly paid till Olennius, firſt centurion of a legion under Tiberius, having been appointed governor of Friſia, inſiſted that the hides of wild bulls ſhould be the models of thoſe of the tribute. This was impoſing upon impracticable conditions, as the wild beaſts in the German foreſts were very large, and their cattle very ſmall. Finding it impoſſible to obey this new law, they firſt parted with their herds, then with their lands, and at laſt ſurrendered their wives and children to bondage, in payment of the rigorous exaction. When their remonſtrances were fruitleſs, they had recourſe to arms, and hung upon trees the ſoldiers who levied the tribute. Olennius made his eſcape, and the Friſians purſued him; but by the whole force of the 5th legion ſent out againſt them, they were at length repulſed. They remained, however, in arms for 20 years, till Corbulo, A.D. 47, conſtrained them to ſubmit peaceably to the Roman yoke, to give hoſtages, and to reſtrain themſelves within the limits of the territory, which he aſſigned them. He preſcribed their form of government, made their laws, gave them a ſenate and magiſtrates, and to keep them perfectly in fear, he built a fort in the middle of their country, and ſtrongly garriſoned it. In the reign of Nero, the Friſons took with them their wives and children to ſettle on the lands near the Rhine, which the Romans had reſerved for their ſoldiers and left uncultivated. They built huts, ſowed the ground, and uſed theſe lands as if they had been their own; but they were made to underſtand that the Romans would fall upon them, if they did not return to their old places of abode, or obtain the emperor's leave to ſettle there. The Friſians, not being able to conceive how any one could be jealous of the poſſeſſion of a country which was applied to no uſe, agreed to apply to the emperor. Two of their magiſtrates were ſent to Rome; and though they were treated with reſpect by the emperor, their requeſt was denied. The Friſons were obliged to leave the lands which they had occupied; and on their refuſing to obey, foreign troops were ſent who compelled them by force, and killed or made priſoners thoſe who perſiſted in their obſtinacy. We have already mentioned other particulars relating to this people under the article FRIESLAND, to which we refer.

FRIST, a term among *Merchants* for ſelling goods upon credit.

FRIT, or FRITT, in the *Glaſs Manufacture*, is the matter, or ingredients, whereof glaſs is to be made; when they have been calcined, or baked in a furnace.

A ſalt drawn from the aſhes of the plant kali, or from fern, or other plants mixed with ſand, or flint, and baked together, makes an opake maſs, called by glaſs-men frit; probably from the Italian *frittare*, to fry; or becauſe the frit, when melted, runs into lumps, like fritters, called by the Italians *fritelli*.

Frit, by the ancients, was called *hammonitrum*, or *ammonitrum*, of αμμος, *ſand*, and νιτρον, *nitre*: under which name it is deſcribed by Pliny thus: fine ſand from the Volturnian ſea, mixed with three times the quantity of nitre, and melted, makes a maſs called ammonitrum; which being re-baked, makes a pure glaſs. Hiſt. Nat. lib. xxxvi. cap. 26.

Frit, Neri obſerves, is only the calx of the materials which make glaſs; which though they might be melted, and glaſs be made, without thus calcining them, yet it would take up much more time. This calcining, or making, of frit, ſerves to mix and incorporate the materials together, and to evaporate all the ſuperfluous humidity. The frit, once made, is readily fuſed, and turned into glaſs.

There are three kinds of frits; the firſt, *cryſtal* frit, or that for cryſtal metal; made with ſalt of pulverine and ſand.

The ſecond, and ordinary frit, is made of the bare aſhes of pulverine, or barilla, without extracting the ſalt from them. This makes the ordinary white, or cryſtal metal.

The third is frit for green glaſſes, made of common aſhes, without any preparation. This laſt frit will require ten or twelve hours baking.

The materials in each are to be finely powdered, waſhed and ſearced; then equally mixed, and frequently ſtirred together in the melting pot. For the reſt, ſee GLASS, and CRYSTAL.

FRITBURG. See FRIBURGH.

FRITH, JOHN, in *Biography*, one of the earlieſt Engliſh martyrs to the principles of the Reformation, was born at Seven-oaks, in Kent, about the beginning of the ſixteenth century. He received his college education at King's college, Cambridge. Here he diſtinguiſhed himſelf by his application and proficiency, and when he was admitted to the degree of B. A. he had a high reputation as a firſt rate linguiſt, and well-informed general ſcholar. On this account he was made one of the junior canons of the New Inſtitution, now Chriſt-church, in the univerſity of Oxford. In 1525 he was incorporated at Oxford in the ſame degree which he had taken at Cambridge. Before this, however, he had become the friend and intimate of William Tyndale, by whoſe means he had obtained a thorough conviction of the corruptions and errors of popery, and had adopted the principles of the reformers. On this account he was confined priſoner ſome time, and afterwards went beyond ſeas, where he became confirmed in his opinions, and reſolved to return to his native country and devote himſelf to the propagation of them. In 1631 he embarked for England with this determination, leaving behind him a wife whom he had married; after this we hear no more of him till we find him wandering about from place to place reduced to great diſtreſs. So deplorable and mean was his appearance, that at Reading he was taken up by the magiſtrates, who, in thoſe days, not unfrequently looked upon poverty as a crime, and put into the ſtocks. In this ſituation, ſo unworthy a man of letters, he refuſed to give any account of himſelf, till preſſed by hunger he ſent for the ſchool-maſter of the town, with whom he converſed in the Latin language, and to whom he made known his wants, and exhibited thoſe evidences of erudition and talent which he poſſeſſed, and which ſhould have claimed, as they really merited, a very different treatment. Frith now, by the humane interference of the ſchool-maſter, was liberated, and his wants ſupplied. Afterwards he came to London, where, through an honourable zeal for the truth, he was found endeavouring to make proſelytes, and was ſeized by the emiſſaries of the lord-chancellor, ſir Thos. More, and committed to the Tower in the year 1533. Frith was not contented with pleading the cauſe of the reformation by converſation and diſcourſe, but drew up ſeveral tracts which he privately circulated among the converts to the new doctrines. Among theſe was a treatiſe on the Euchariſt, ſhewing that the belief of the corporal preſence of Chriſt was not a neceſſary article of faith. This was the firſt treatiſe written by the reformers of England on that ſide of the queſtion. It was anſwered by ſir Thos. More, who undertook alſo to reaſon with the author, but Frith was not eaſily changed: he wrote a reply to ſir Thomas which was not publiſhed till ſome years afterwards. When no conviction could be produced on the mind of this honeſt man by the way of argument, other means were adopted: he was brought before an epiſcopal commiſſion at St. Paul's cathedral, where he was interrogated on the ſubjects of tranſubſtantiation and purgatory, and many efforts were made to perſuade, or intimidate him to renounce the notions which he entertained reſpecting thoſe doctrines, and to conform to the creed of the catholic church. He was, however, unmoved, and perſiſted in maintaining the truth, nor could he be perſuaded to make any conceſſion; accordingly the biſhop of London, with much affected ſorrow and commiſeration, pronounced upon him ſentence of condemnation as an obſtinate heretic, and he was delivered over to the ſecular power. In purſuance of this ſentence a writ was iſſued for his execution, and he was in a few days burnt at Smithfield, maintaining his fortitude to the laſt, and charitably extending his forgiveneſs to a bigotted prieſt who endeavoured to perſuade the people that they ought no more to pray for him than for a dog. He was author of many pieces on the controverted points of theology which were originally printed ſeparately, and at different periods, but which were afterwards collected into a folio volume in 1573. Gen. Biog.

FRITH. See FRYTH.

FRITHGILD, was anciently the ſame with what we now call a *guild*, or a *fraternity*, or *company*. See GILD.

FRITILLARIA, in *Botany*, from *fritillus*, which ſome take for a cheſs-board, and which in that ſenſe alludes to the chequered nature of the petals. *Fritillus* however is uſed by Juvenal and Perſius for a dice-box, and is ſuppoſed to have expreſſed the rattling ſound of the dice.—Chequered Daffodil, or Snake's-head.—Linn. Gen. 164. Schreb. 219. Willd. Sp. Pl. v. 2. 90. Sm. Fl. Brit. 360. Ait. Hort. Kew. v. 1. 432. Mart. Mill. Dict. v. 2. Tourn. t. 201. Juſſ. 48. Gærtn. t. 17. Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Coronariæ*, Linn. *Lilia*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* bell-ſhaped, ſpreading at the baſe, of ſix oblong parallel petals. Nectary a little cell in the baſe of each petal. *Stam.* Filaments ſix, awl-ſhaped, cloſe to the ſtyle; anthers vertical, erect, oblong, quadrangular, extending to the open part of the corolla. *Piſt.* Germen ſuperior, oblong, triangular, obtuſe; ſtyle ſimple, longer than the ſtamens; ſtigma three-lobed, ſpreading, obtuſe. *Peric.* Capſule oblong, obtuſe, three-lobed, of three cells, and three valves. *Seeds* numerous, horizontal, flat, rounded at the outer edge, ranged in two rows.

Obſ. *Fritillaria* of Tournefort has an oblong nectary, and an even capſule.

Corona Imperialis of Tournefort, t. 197, 198, has a hemiſpherical nectary, and a ſharp-edged capſule.

Eſſ. Ch. Corolla inferior, bell-ſhaped, of ſix petals, with a nectariferous cavity above the claw of each. Stamens nearly the length of the corolla. Calyx none. Seeds flat.

1. F. *imperialis*. Crown Imperial. Linn. Sp. Pl. 435. Curt. Mag. t. 194. 1215.—"Cluſter of many flowers, crowned with leaves, the ſtem naked below it."—Suppoſed to be a native of Perſia. It was brought from Conſtantinople to the gardens of Europe, where it is quite hardy. The *root* is a large ſcaly bulb. *Herb* of very quick growth, fœtid, two or three feet high, ſucculent, of a fine ſhining green, conſiſting of a thick, ſimple, ſtraight, leafy ſtem. *Leaves* ſcattered, linear-oblong, twiſted. *Flowers* drooping, large, orange or lemon-coloured. *Fruit* erect. There is a variety with variegated leaves, and one with a red ſtem.

2. F. *perſica*. Perſian Fritillary.—Linn. Sp. Pl. 436. (Lilium perſicum; Ger. em. 201.)—"Cluſter nearly naked. Leaves oblique."—Suppoſed alſo to be a native of Perſia. It was cultivated in England by Gerarde and Parkinſon, but is not very common, though quite hardy. The *herbage* is glaucous. *Flowers* numerous, dull purple, ſmaller than in any other ſpecies.

A variety with fewer but brighter flowers is given in Curt. Mag. t. 962. This is the β of Linnæus.

3. F. *verticillata*. Whorled Fritillary. Willd. Sp. Pl. v. 2. 91.—"Leaves whorled, linear-lanceolate. Stem ſingle-flowered."—Native of Siberia. *Stem* a foot high, erect. *Leaves* four or five in a whorl, ſeſſile, linear, very ſlender-pointed, the ends curled when dry, ſo as to reſemble tendrils. *Flower* terminal. *Willdenow*.

4. F. *obliqua*. Violet-flowered Fritillary. Curt. Mag. t. 857.—"Leaves very glaucous, ſcattered, twiſted. Flowers few, on terminal leafy ſtalks. Corolla obovate, connivent."—Country unknown. *Flowers* two to four, thrice as large as in *F. perſica*. A hardy early-flowering ſpecies. *Gawler*.

5. F. *pyre-*

5. F. *pyrenaica*. Pyrenean Fritillary. Linn. Sp. Pl. ed. 1, 304, excluding the quotation of Hort. Cliff. (which moreover ſhould be Hort. Upſal.) Sm. Prod. Fl. Græc. Sibth. v. 1. 228. Curt. Mag. t. 664.—"Leaves ſcattered, flattiſh; the lower ones broadeſt and bluntеſt. Petals recurved at the ſummit. Nectary roundiſh."—Native of the Pyrenean mountains. *Cluſius*. Of mount Parnaſſus. *Sibthorp*.—A ſpan high. *Leaves* five to ſeven, glaucous, thick and leathery, rather glaucous. *Petals* tawny-purple, yelloviſh internally, as well as at the extremity, which is dilated and recurved. The three outer ones are gibbous at the baſe.

6. F. *racemoſa*. Cluſter-flowered Fritillary. Curt. Mag. t. 952. 1216. (F. pyrenaica; Linn. Sp. Pl. ed. 2. 436). —Leaves linear, pointed, flattiſh. Cluſter leafy, of ſeveral flowers. Petals nearly erect, all gibbous at the baſe. Nectary oblong.—Native of Siberia, &c. It is not rare in gardens about London, and greatly reſembles the following, except in having more numerous and ſmaller *flowers*.

7. F. *Meleagris*. Common Fritillary. Linn. Sp. Pl. 436. Curt. Lond. faſc. 3. t. 20. Sm. Engl. Bot. t. 622. Fl. Dan. t. 972. Jacq. Auſtr. app. t. 32.—Leaves linear, pointed, keeled. Stem ſingle-flowered. Petals ſlightly incurved. Nectary linear.—Native of various parts of Europe, flowering in April. *Stem* a foot high, always ſimple, bearing one large pendulous *flower*, regularly chequered with purple, or with different whites. All the *petals* are gibbous at the baſe, their tips ſlightly inflexed.

8. F. *latifolia*. Broad-leaved Fritillary. Curt. Mag. t. 853. 1207. Redouté Lil. v. 1. t. 51.—Leaves elliptic-lanceolate, obtuſe; the upper ones crowded. Stem ſingle-flowered. Petals ſlightly incurved. Nectary oblong.—Native of Mount Caucaſus. The broad *leaves*, numerous at the top of the ſtem, diſtinguiſh this from the laſt. The *flower* alſo is rather larger, and leſs regularly chequered. The *leaves* are leſs glaucous. It is not rare in gardens.

FRITILLARIA, in *Gardening*, comprehends plants of the bulbous-rooted perennial flowery kind; of which the ſpecies moſtly cultivated are the common fritillary, or chequered lily (F. meleagris); the black fritillary (F. pyrenaica); the imperial fritillary, or crown imperial (F. imperialis); the Perſian fritillary, or Perſian lily, (F. Perſica).

Of the firſt of which there are numerous varieties, as the common purple; the blood red; the great purple or red; the white; the double bluſh; the purple yellow; the chequered yellow; the great yellow Italian; the ſmall Italian; the ſmall Portugal yellow; the black, and the Spaniſh black.

And of the third there are varieties with yellow flowers; with large flowers; and with double flowers; but that which has two or three whorls of flowers above each other makes the fineſt appearance, though it ſeldom produces its flowers after this manner the firſt year after removing it.

The laſt ſort has a variety which has a much ſhorter ſtem and ſmaller leaves; the ſtem branches out at the top into ſeveral ſmall peduncles, each ſuſtaining one dark-coloured flower, which is termed the dwarf Perſian lily.

Theſe plants are all of them highly deſerving of places in the flower-garden.

Method of Culture.—The common mode of propagation in all theſe plants is by off-ſets from the ſides of their roots, ſeparated every ſecond or third year; the proper time for which is when their flower-ſtalks decay, taking the whole roots up entirely, and ſeparating them into diſtinct roots, then planting the ſmaller off-ſets by themſelves in nurſery-beds, to remain a year or two, to acquire a flowering ſtate; and the larger roots, where they are to remain for flowering in the ſummer ſeaſon.

They are likewiſe capable of being propagated by ſeed; but this is principally practiſed for new varieties, and the proceſs is tedious; the fritillary and Perſian lily being three years, and the crown imperial ſometimes ſix or ſeven, before they flower in perfection. The ſeeds may be ſown in the beginning of autumn in large wide pots, or in boxes of ſimilar width, filled with light, mellow earth, each ſort ſeparate, covering them evenly with fine earth half an inch deep, placing the pots, &c. to have only the morning ſun all ſummer, or during hot, dry weather, and in the full ſun in winter and ſpring: the plants will appear in the ſpring, which after the firſt or ſecond year's growth, when the leaves decay in ſummer, may be taken up, and the whole planted immediately in nurſery-beds, in ſhallow drills, four inches aſunder, to remain till they flower in that ſituation.

They are all hardy, and highly ornamental plants for the borders, clumps, and other parts; the fourth ſort being ſet backwards, the third in the middle, and the others forwards, in order that they may make the fineſt appearance poſſible.

FRITZ, GASPARO, in *Biography*, a very agreeable performer on the violin, and compoſer for that inſtrument. He had ſtudied under the celebrated violiniſt, Somis, and in the year 1770, he had been reſident at Geneva 30 years. He was well known to all Engliſh travellers who had entered or quitted Italy, through Geneva, during that period. We heard him perform one of his own ſolos in 1770, which, though extremely difficult, was pleaſing; and notwithſtanding his time of life, he executed it with as much ſpirit as a young man of twenty-five; his bowing and expreſſion were admirable, and he muſt have been a *real* lover of his art to keep in ſuch high practice, with ſo few opportunities of diſplaying his talents, or of receiving their due reward. When he viſited Paris, about the middle of the laſt century, his ſtyle of compoſition was ſo much too good for the taſte which then prevailed in France, that he had the honour of being hiſſed at the concert ſpirituel, as Pugin, one of the beſt ſcholars of Tartini, was afterwards.

FRITZLAR, in *Geography*, a town of Germany, in the principality of Lower Heſſe; ſituated on the Eder; containing two colleges and a convent; 13 miles S.S.W. of Caſſel. N. lat. 50° 8′. E. long. 9° 13′

FRIULI, a province of Italy, bounded on the N. by Carinthia, on the E. by the county of Goritz, and the gulf of Trieſte; on the S. by the gulf of Venice, and on the W. by the Treviſan, the Feltrin, and the Belluneſe; about 52 miles from north to ſouth, and 45 from eaſt to weſt. This country was taken from the Lombards by Charlemagne, and has belonged to the Venetians from the year 1420. It is partly flat and partly mountainous; the hilly part toward Germany is the moſt ſterile and uninhabited, and forms part of the Alps which ſeparate Italy from Germany; and on the other ſide this country is interſected by another ridge of mountains. The roads through theſe mountains to Germany are in ſome parts ſo narrow, that it is dangerous to paſs them either on foot or on horſeback; and only the paſſes, Chiuſa di Venzone, Tolmino, and Lubiana, admit of waggons and artillery. The flat part of Friuli is very fertile, and the country produces a quantity of timber and fire-wood, game, all kinds of grain, fruit and good wine, among which is the famous "piccali." The breeding of cattle is a very conſiderable occupation of the inhabitants, and the culture of ſilk is ſo extenſive, that it produces yearly 1000 *cwt.* which is deemed ſome of the fineſt in Italy. The principal rivers are, the Tagliamento, the Meduna, Cellina, Stella, Torre, and Natiſone. The

inhabitants, denominated Furlani, ſpeak a dialect reſembling that of the ancient French language, differing widely from the Italian or German idiom: they are conſidered as the moſt hot-headed, indolent, and wild inhabitants of Italy. The whole province is divided into the dioceſes of Udina and Concordia, and contained, in the year 1795, 365,512 perſons, who live in 4 cities, 20 ſmall towns and boroughs, and 600 villages. By the peace of Luneville the whole country of Friuli was ceded to the emperor of Auſtria; but afterwards, agreeably to the peace of Preſburg, it was taken from Auſtria and annexed to the new kingdom of Italy.

FRIULI, or *Citta di Friuli*, a town of Italy, in a country of the ſame name above-deſcribed; the ſee of a biſhop, the ſuffragan of Aquileia. It is ſituated at the foot of the mountains, which ſeparate Friuli from Carniola, on the river Naiſonne, and is the ſecond capital of the province. Acroſs the river which riſes near the town is a bridge, with two arches, 220 feet in length, and 75 feet high. The town is well built, and contains a collegiate church, with a chapter; three monaſteries, 62 nunneries, and 4000 inhabitants. N. lat. 46° 10′. E. long. 31° 21′.

FRIZE, or FRIEZE, in *Architecture*, a part of the entablature of columns, more uſually written and pronounced *freeze*.

FRIZE, or *Freeze*, in *Commerce*, a kind of woollen cloth or ſtuff, for winter wear, being frized, or knapt, on one ſide; whence, in all probability, it derives its name.

Of frizes, ſome are croſſed, others not croſſed: the former are chiefly of Engliſh manufacture, the latter of Iriſh.

FRIZING *of Cloth*, a term in the *Woollen Manufactory*, applied to the forming of the knap of a cloth, or ſtuff, into a number of little hard burrs, or prominences, covering almoſt the whole ground thereof.

Some cloths are only frized on the back ſide, as black cloths; others on the right ſide, as coloured and mixed cloths, ratteens, bays, frizes, &c.

Frizing may be performed two ways; one with the hand, *i. e.* by means of two workmen, who conduct a kind of plank, that ſerves as a frizing inſtrument.

The other way is by a mill, worked either by water, or a horſe; or ſometimes by men. The latter is eſteemed the better way of frizing, becauſe the motion being uniform and regular, the little knobs of the frizing are formed more equably and regularly.

The ſtructure of this uſeful machine is as follows:

The three principal parts are, the frizer, or criſper; the frizing-table; and the drawer, or beam. The two firſt are two equal planks, or boards, each about ten feet long, and fifteen inches broad; differing only in this, that the frizing-table is lined or covered with a kind of coarſe woollen ſtuff, of a rough, ſturdy knap, and that the frizer is incruſtated with a kind of cement compoſed of glue, gum Arabic, and yellow ſand, with a little aqua vitæ, or urine. The beam or drawer, thus called becauſe it draws the ſtuff from between the frize and frizing-table, is a wooden roller, beſet all over with little, fine, ſhort points or ends of wire, like thoſe of cards uſed in carding of wool.

The diſpoſition and uſe of the machine are thus: the table ſtands immoveable, and bears or ſuſtains the cloth to be frized, which is laid with that ſide uppermoſt on which the knap is to be raiſed. Over the table is placed the frizer, at ſuch a diſtance from it as to give room for the ſtuff to be paſſed between them; ſo that the frizer, having a very ſlow, ſemi-circular motion, meeting the long hairs or knap of the cloth, twiſts and rolls them into little knobs or burrs, while, at the ſame time, the drawer, which is continually turning, draws away the ſtuff from under the frizer, and winds it over its own points.

All that the workman has to do while the machine is going, is to ſtretch the ſtuff on the table as faſt as the drawer takes it off, and, from time to time, to take off the ſtuff from the points of the drawer.

It has already been obſerved, that the frizing-table is lined with ſtuff of ſhort, ſtiff, ſtubby knap; the uſe whereof is to detain the cloth between the table and frizer, long enough for the grain to be formed, that the drawer may not take it away too readily; which otherwiſe muſt be the caſe, inaſmuch as it is not held by any thing at the other end.

It were needleſs to ſay any thing particular of the manner of frizing ſtuffs with the hand, it being the aim of the workmen to imitate, as near as they can, with their wooden inſtrument, the ſlow, equable, and circular motion of this machine. It needs only be added, that their frizer is but about two feet long, and one broad; and that to form the knap more eaſily, they moiſten the ſurface of the ſtuff lightly with water, mingled with whites of eggs, or honey.

FROBEN, JOHN, in *Biography*, an eminent printer, was born at Hammelburg in Franconia. He enjoyed the advantages of a liberal education, and acquired conſiderable reputation at Baſil. As the buſineſs of a printer was at that period connected with the profeſſion of letters, Froben was induced to learn it, and to ſet up a preſs in the city of Baſil, where he not only became eminent in the art, but ſupported its dignity and utility by a ſcrupulous choice in the authors that he printed. He never ſuffered improper writings to iſſue from his preſs, but devoted it to the ſervice of ſound and uſeful learning. The reputation of Froben was ſo high that Eraſmus ſettled at Baſil for the ſake of having his works printed by him. That great ſcholar ſoon became intimately connected with Froben, and always teſtified for him the higheſt eſteem and affection. From Froben's preſs iſſued the works of Eraſmus, in nine volumes folio, and alſo thoſe of St. Jerome and Auguſtine, which Eraſmus corrected and reviſed. Theſe are ſaid to be the moſt correct of Froben's editions. He intended printing the Greek fathers, but was prevented by his death, which happened in 1527. He was ſincerely lamented by Eraſmus, who wrote, on the occaſion, a Greek and Latin epitaph. Jerome Froben, ſon of John, and his ſucceſſor in the printing-office, in conjunction with Nicholas Epiſcopius, carried into effect the deſign of printing the Greek fathers. At the houſe of Jerome Froben Eraſmus died, after an eminently uſeful life. A catalogue of all the works printed at the Frobenian preſs was publiſhed in 1564. Moreri.

FROBENIUS's *Ætherial Spirit*. See ÆTHER and SPIRIT.

FROBERGER, JOHN, JACOB, in *Biography*, organiſt to the emperor Ferdinand III., who in his youth had been ſent to Rome to ſtudy under the celebrated Freſcobaldi, was regarded about the middle of the laſt century as the greateſt performer on the organ in Germany. He is much celebrated for his abilities by Kircher, who has inſerted a fantaſia of his compoſition in his "Muſurgia," upon the hexachord *ut, re, mi, fa, ſol, la*, accommodated to the organ. Few of his compoſitions were publiſhed in his life time; but, according to Walther, his pieces for keyed inſtruments were ſtill highly eſteemed among organiſts in 1732, and heard with admiration. Mr. Marpurg ſays, that his works will be always models for regular good fugues. (Art de la Fugue, Berlin, 1756.) His compoſitions for the harpſichord were publiſhed at Mayence in 1696. And ſo late as 1714, the moſt important of his works appeared, for the firſt time, at Francfort on the Mayne.

Diverſe

Strahan and Preſton,
New-Street Square, London.

"Diverſe ingegnoſiſſime, rariſſime et non mai più viſte curioſe partite, di toccaté, canzone, ricercate, allemande, correnti, ſarabande, et gighe, di cimbali, organi, iſtromenti, dal eccelentiſſimo, e famoſiſſimo organiſta, Giov. Giacomo Froberger, per la prima volta col diligentiſſimo ſtudio ſtampate."

FROBISHER, *Sir* MARTIN, was born near Doncaſter, Yorkſhire, and brought up for the ſea ſervice, in which he became one of the moſt eminent navigators of his time, and was the firſt Engliſhman that attempted to find out a north-weſt paſſage to China. It was long before he was enabled to make the trial. He applied to his friends, and the merchants in general, but they were unwilling to embark in ſo hazardous an enterprize: at length finding that there was no chance of ſucceſs from private encouragement, he boldly applied to the court of queen Elizabeth, and by this was enabled to fit out a ſmall equipment conſiſting of two barks of twenty-five tons burthen each, and a pinnace of ten tons. He ſailed from Deptford June 8th, 1576, and in about ſix weeks made the coaſt of Greenland. Here he ſpent ſome time in exploring and making ſuch obſervations as might be uſeful to himſelf and future navigators, and then, on Auguſt 11th, entered and ſailed up the ſtrait which has ever ſince borne his name. This is in N. lat. 62° 50', on the eaſtern ſide of New Greenland, which terminates to the ſouth at Cape Farewell. Having touched at various parts, he brought his veſſel to an anchor under Burcher's iſland, where they went on ſhore, and had ſome communication with the natives; but at the ſame time he had the misfortune to loſe five of his men, who were captured by the people. Having endeavoured in vain to recover his ſailors, he embarked for England, where he arrived ſafe on the 2d of October. He had taken poſſeſſion of the country in the name of queen Elizabeth, and in proof of the diſcovery and poſſeſſion, he ordered his men to bring him whatever they could find. One of them returned with a large piece of black ſtone, very heavy, but in other reſpects reſembling ſea-coal: it was probably a kind of pyrite, and was, upon trial, after their return, ſaid to contain a portion of gold. A new Peru was now anticipated, and a ſecond voyage determined on in the following ſpring. At this period of our mineralogical knowledge it is certain that the report of gold being found in this black ſtony ſubſtance muſt have proceeded from ignorance, or perhaps from the deſire of being ſo far patronized by public conſent, as to obtain means for proſecuting farther diſcoveries. The fraud, if it were a fraud, ſucceeded; the queen lent Frobiſher a ſhip of the royal navy, of two hundred tons, to which he added two ſmall barks. Volunteers, ſome from the firſt families in the kingdom, preſſed in from all quarters; but as the number was reſtricted to one hundred and forty, many were obliged to return diſappointed and uneaſy. Such was the deſire of gold, that the commiſſion under which Frobiſher ſet out in this voyage directed him "only to ſearch for ore, and to remit diſcovery till another time." He ſailed on the 31ſt of May, 1577, and proceeding to his former ſtrait, explored all its coaſts and bays, and landed on ſeveral iſlands, where the crews furniſhed themſelves with a quantity of the ſuppoſed ore. On their return the cargo was examined, and thought to promiſe much wealth: a third expedition was planned, and inſtead of three, fifteen veſſels were fitted out for the purpoſe of being laden, as they expected, with the precious mineral. This was the laſt of the expeditions, for the true nature and real value of the ſubſtances found in that bleak country were now properly appreciated. There is no account left us how Frobiſher ſpent his time from the termination of this expedition till the year 1585, when he was appointed to the command of the Aid in ſir Francis Drake's expedition to the Weſt Indies, which took St. Domingo in Hiſpaniola, Carthagena on the continent, and Santa Juſtina in Florida, three towns of conſiderable importance. In 1588 he bravely exerted himſelf in defence of his country againſt the famous Armada, having the command of the Triumph, one of three of the largeſt ſhips in the navy, and which had on board the greateſt number of men of any in the whole Engliſh fleet. For his ſervices on this important occaſion he received the honour of knighthood. He afterwards commanded ſquadrons againſt the Spaniards in 1590 and 1592, and took two very rich prizes. In 1594 he was ſent with four men of war to the aſſiſtance of Henry IV. king of France againſt a body of the leaguers and Spaniards, then in poſſeſſion of part of Bretagne; but in an attack upon a fort near Breſt he received a mortal wound from a ſhot, of which he died after his return home. He was buried at Plymouth. Sir Martin Frobiſher is ſaid to have had the roughneſs and violence which frequently characterize the profeſſion, and he was unqueſtionably a man of great and undaunted courage, and inferior to no one of his age in experience and conduct as a naval commander. Biog. Brit.

FROBISHER'S *Straits*, in *Geography*, a narrow ſea on the weſt of Davis's ſtrait, to the ſouth of cape Walſingham of Frobiſher. N. lat. 61° 50' to 63° 20. W. long. 65° to 70°.

FRODSHAM, a ſmall town in the hundred of Eddiſbury, and county of Cheſter, is pleaſantly ſituated on an elevated ſpot, at a ſhort diſtance from the confluence of the rivers Weaver and Merſey, two miles diſtant from Cheſter, and one hundred and ninety-three from London. Here was formerly a fortified manſion, called Maurice caſtle, which, together with the town, was granted by Edward I. to David, brother to Llewelyn, the laſt ſovereign prince of North Wales; with a view of ſeparating the former, in his affections and intereſt, from that of his family and country: in which unnatural attempt the king was moſt diſaſtrouſly foiled. It ſtood at the weſt end of the town, and was at one time the reſidenee of the Savages, earls Rivers; but having been conſumed by fire in 1642, its ſcite has ſince been occupied by a handſome modern houſe. The town conſiſts of two main ſtreets croſſing each other, and at the upper end of one, on an elevated ſpot called Overton, ſtands the church, an ancient and excellent ſtructure, repaired and beautified in 1790; and near it the free grammar ſchool, with a good houſe for the maſter; which has a cupola on the top intended for an obſervatory. Behind the ſchool is an eminence, where formerly a beacon was erected, thence denominated Beacon-hill, which is cut out into walks, gradually aſcending to the ſummit, and commanding a delightful proſpect of the eſtuaries of the Merſey and the Dee, with the diſtant parts of Lancaſhire and the ſurrounding country. The town is well ſupplied with water by ſeveral ſprings, one of which, uſed as a cold bath, is notable for its power, throwing out the immenſe quantity of 1700 gallons per minute. By the returns made to parliament in 1801, the number of houſes was 272, containing 1551 inhabitants, chiefly employed in the refining of rock-ſalt, and in a ſmall manufacture of coarſe cottons. It has a well ſupplied weekly market on Thurſdays, and two annual fairs. A graving dock and yard have lately been erected for building and repairing veſſels, which promiſes to be of conſiderable utility to the place.

The pariſh is of great extent, being thirty-one miles in circumference, containing ten ſmall villages, beſides the town, and is famous for the great quantities of potatoes cultivated in

Strahan and Preſton,
New-Street Square, London.

in it; the average annual amount of which, for ſome years paſt, has not been leſs than 100,000 buſhels, each weighing nearly one hundred weight: theſe are diſpoſed of to the numerous manufacturers in the adjoining county. This anciently formed part of an extenſive tract called the foreſt of De la Mere, which, in the time of Leland, abounded with red and fallow deer; but at preſent exhibits merely a bleak and dreary waſte in its general aſpect, conſiſting of a ſandy heath, tenanted by rabbits; and the chamber, or centre of the woodlands, is marked by a few ſtunted trees. Hiſtory of Cheſhire, in two volumes 8vo.

FROELICH, Erasmus, in *Biography*, was born at Gratz, in Styria, in 1700. He entered the ſociety of the Jeſuits when he was ſixteen years of age, and was ſo indefatigable and ſucceſsful in his ſtudies, that he was, in a ſhort time, appointed profeſſor of mathematics and belles lettres at Vienna. Here he purſued his ſtudies with great ardour, and made uſe of his ſituation in that city to purſue the medallic ſcience, on which he publiſhed various tracts, chiefly on particular medals. He died in 1758: his principal works are, "Quatuor Tentamina in Re Nummaria," 4to. 1737, and 1750: "Annales rerum et regum Syriæ," 1751, "De Figura Telluris," 4to. 1757.

FROELICHIA, in *Botany*, in honour of Dr. J. A. Froelich, member of the botanical ſociety of Ratiſbon, author of an octavo volume on Gentiana, publiſhed at Erlang in 1796. Willd. Sp. Pl. v. 1. 607. (Billardieria; Vahl. Eclog. v. 1. 13. t. 10.) Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Rubiaceæ*.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, permanent, with four ſlight teeth. *Cor.* of one petal, ſuperior, about an inch long, thick; limb in four linear-lanceolate, widely ſpreading, ſlightly recurved ſegments; thickened and triangular at the tips; acutely carinated above; flat from the middle to the baſe. *Stam.* Filaments four, very ſhort, inſerted into the lower part of the tube; anthers erect, linear, a little prominent. *Piſt.* Germen inferior, elliptical; ſtyle nearly as long as the limb of the corolla; ſtigmas two, oblong, compreſſed, bluntiſh, ſpreading, rather thick. *Peric.* Berry elliptical, dry, corky, hardiſh, ſlightly compreſſed, as long as the nail, crowned with the ſhort permanent tube of the calyx, within which is a ſmall convex calloſity. *Seed* ſolitary, the ſhape of the berry, clothed with a looſe arillus of a paper-like texture, without any diviſion.

Eſſ. Ch. Calyx ſuperior, with four teeth. Corolla tubular. Berry dry, with one ſeed, inveſted with an arillus.

1. F. *paniculata*. Native of the iſland of Trinidad. A ſhrub, with ſquare *branches*. *Leaves* oppoſite, elliptic-lanceolate, pointed, entire, ſmooth. *Panicle* terminal, with ſmooth purpliſh branches, divided and ſubdivided, bearing numerous flowers. This genus is nearly akin to *Coffea*, and is ſuſpected by Vahl to be ſcarcely diſtinct from Aublet's *Couſſarea*. The colour of the flowers is not mentioned, Vahl having ſeen dried ſpecimens only, but they are probably white.

FROG, in *Zoology*. See Rana. This creature bears the experiments of the air-pump better than moſt other animals. It will breathe ſome time after the extraction of the air, but at length the viſible motion of the throat will ceaſe, and the body ſwell a little. After three hours lying in this condition, when no farther ſign of life appears, if the animal be placed in the open air, a few hours will recover it to its former life and vigour. The ſame animal, put into a receiver exhauſted of the air, but nearly filled with water, will live many hours under the water, and ſeem to reſpire, but in five or ſix hours it will die. The larger and luſtier frogs live longer than the young ones in the receiver. Phil. Tranſ. N° 62.

The frog affords the curious in microſcopic obſervations a very beautiful view of the circulation of the blood; but the method of examining it to advantage was never hit upon till the contrivance of the late ingenious Dr. Stuart for that purpoſe. This he did by the ſolar microſcope in the following manner: The looking glaſs, tube, and convex lens, are the ſame in this as in the common ſolar microſcope; but inſtead of the little pocket microſcope of Wilſon, he uſed the belly-part of the common large reflecting one, fixed horizontally on a pedeſtal, juſt at an equal height with the tube. This ſtands on a little ſhelf made to ſupport it; and to its ſnout, which lies on a level with the tube, the magnifiers are ſcrewed: the object, being extended and faſtened with ſtrings and pins on a frame contrived for that purpoſe, is applied between the tube and the magnifier, whereby the ſun's rays, reflected from the looking-glaſs, through the tube, upon the object, paſs on through the magnifier, and exhibit upon the ſcreen an image of the object moſt prodigiouſly enlarged.

To view a frog with this apparatus, the ſkin of the belly is to be opened from near the anus to the throat, and then giving it a little ſnip ſide-ways both at the top and bottom, and ſticking a fiſh-hook into each corner of the ſkin, it was eaſily extended before the microſcope, and ſhewed on the ſcreen the moſt beautiful view imaginable of the veins and arteries of the ſkin, with the blood circulating through them. In the arteries thus viewed, the blood is ſeen to ſtop, and recede a little at every pulſation by the dilatation, and ruſh forcibly on again by the contraction of the heart; while in the veins it ever kept the ſame equable and uniform current, with a ſurpriſing rapidity; and when the ſcreen was removed farther back, and the object by that means more enlarged, the alternate expanſion and contraction of the ſides of the arteries were very viſible. After this, the abdomen of the frog being opened, and the muſcles of it being extended before the microſcope in the ſame manner as the ſkin was, the ſtructure of theſe muſcles is beautifully ſeen, being all made up of bundles of tranſparent ſtrings of fibres, all lying parallel to one another, and joined by a common membrane.

Theſe ſtrings or fibres appeared alſo through their whole length made up of roundiſh veſicles, and reſembled ruſhes divided longitudinally; but there is no certainty of any circulation being ſeen in theſe.

When this has been ſufficiently examined, a part of the creature's guts being pulled out and extended with the meſentery, there is ſeen the fineſt of all views of the circulation of the blood. Words are not able to deſcribe this wonderful ſcene. The blood is ſeen paſſing through numberleſs veſſels at one and the ſame inſtant, in ſome one way, and in others directly the contrary. Several of the veſſels are thus magnified to more than an inch in diameter, and the globules of the blood rolling through them appear nearly as large as pepper-corns; while in many of the minuteſt veſſels only ſingle globules were able to find their paſſage, and that too by changing their ſhape into an oblong ſpheroid. The pulſation and acceleration of the blood in the arteries are thus alſo very beautifully ſeen. As the animal under examination grows languid and near expiring, the blood in the arteries will often ſtop on a ſudden, and ſeem as if it were coagulating, and will then run back for ſome time; after which it will again recover its natural courſe with a great deal of rapidity. A due conſideration of theſe particulars may poſſibly account for the intermiſſions,

ſtarts,

ſtarts, and irregularities, in the pulſe of perſons near death. Baker's Microſcope, p. 132—136.

FROG, among *Farriers*, the ſame with fruſh. See FRUSH.

FROG's-*bit*, in *Botany*. See HYDROCHARIS.

FROG, *Bull*. See BULL-*frog*.

FROG-*fiſh*, in *Ichthyology*, an Engliſh name for the *rana-piſcatrix*, or *lophius*. See LOPHIUS *Piſcatorius*.

FROG-*fiſh of Surinam*, is produced by the transformation of a frog into a fiſh. The frog, in its firſt ſtate, is ſpotted with brown, yellow, and green, but paler on the belly; the hinder feet are webbed like thoſe of a gooſe, but the fore-feet are without webs: the firſt change this frog undergoes is by the growing out of a tail; after which it gradually acquires the ſhape of a fiſh, the two fore-feet decreaſing and periſhing by degrees, and then the hinder legs; and, at length, the frog is changed into a perfect fiſh. The Indians and Europeans of Surinam call theſe fiſhes jakies; they are cartilaginous, and of a ſubſtance like our muſtela, and very delicate food. A bone or cartilage runs down the back, with ſmall bones all over the body, which is divided into equal parts; they are adorned with beautiful ſcales, and are firſt of a darkiſh colour, and afterwards grey. See an account of the ſeveral transformations of this frog, illuſtrated with drawings, and of the transformation of fiſhes into frogs, in Phil. Tranſ. vol. li. p. 2. art. 60. p. 653, &c.

FROG, in *Geography*, a town of America, in the ſtate of Georgia; 6 miles W. of Tugeloo.

FROG, *Lake*, a lake of N. America, in N. lat. 53° 15'. W. long. 91° 50'.

FROG, *Petrified*, in *Natural Hiſtory*. Among the petrifactions found in the Stirling limeſtone, or ſwineſtone of Oering, frogs (ranæ) have been mentioned; but it does not appear that their perfect identity with the recent animal has been made out. Among the numerous inſtances of animals, like frogs and toads, ſaid to be found alive in ſtone, clay, and other mineral ſubſtances, ſeveral inſtances of which have been related to the writer of this by quarry-men and others of veracity, ſo that he can ſcarcely doubt the fact, at leaſt of animals not petrified or altered from their living ſtate, being thus found; it is to be lamented, that none of them have been ſubmitted to examination and diſſection by a competent anatomiſt, who might decide on their identity with the recent ſpecies, in the genus to which they ſeem referable. See TOAD.

FROHBURG, in *Geography*, a town of Germany, in the circle of Leipſic, ſituated on the Wichra; 15 miles S.S.E. of Leipſic. The inhabitants manufacture ſtuff and earthen ware. N. lat. 51° 5'. E. long. 12° 28'.

FROHNA, a town of Germany, in the circle of Erzgeburg; 8 miles N.W. of Chemnitz.

FROHNSDORF, a town of Germany, in the circle of Thuringia; 7 miles S.E of Weiſſenſee.

FROJAN, a town of Spain, in Galicia; 22 miles N.N.E. of Orenſe.

FROIDMONT, LIBERT, in *Biography*, was born in a country town, ſituated between Liege and Maeſtricht, in the year 1587. He was profeſſor of philoſophy in the univerſity of Louvain, and in 1633 was appointed dean of St. Peter's in that city. After this he was created doctor of divinity, and ſucceeded Janſenius, who was appointed biſhop of Ypres, as interpreter of the ſacred ſcriptures. He died in 1653, at the age of ſixty-ſix. His writings are proofs of his great learning on various ſubjects. He was author of "Diſſertatio de Cometa," Anni. 1618. "Meteorologicorum Libri V." "Brevis Anatomia hominis." Latin commentaries on the Acts of the Apoſtles, and on the epiſtles of St. Paul in folio, and on other works. The commentaries are in much repute, though they are, in a meaſure, abridged from the works of Eſtius. Moreri.

FROJERED, in *Geography*, a town of Sweden, in Weſt-Gothland; 70 miles E. of Uddevalla.

FROISSART, JOHN, in *Biography*, an early French hiſtorian and poet, was born at Valenciennes in 1337. The works of this writer have lately been reprinted, and obtained a moſt extenſive circulation; ſtill there is a great lack of materials for an account of his life. In ſome manuſcripts he is repreſented as a knight, in moſt as an eccleſiaſtic, and from a paſſage in his own works it is inferred that he was at one period a merchant. It is not known who was his father, but it is ſuppoſed that he was a herald painter, a circumſtance which would account for the attachment of the ſon to the heraldic ſcience, and to the manners of chivalry by which he is diſtinguiſhed. He began his hiſtory before he had attained to the age of manhood, and continued it till within a ſhort time of his death, the date of which has not been aſcertained, though there are facts which lead one to imagine that it did not happen till about 1420, and his hiſtory is brought down to the beginning of that century. A large portion of his life was employed in travelling from court to court, with a view of collecting materials for his "Chronicles." He was patronized by princes of oppoſite intereſts, and was perſonally acquainted with the chief actors in the ſcenes which he deſcribes. The mode which he adopted to obtain information was to procure admiſſion to the ſociety of thoſe who had borne a part in all the principal events of their times, and to live with them on terms of familiarity; and as he was well and kindly received by both parties, he had an opportunity of comparing the oppoſite accounts. Philippa, queen of Edward III. of England, was one of his earlieſt and beſt friends; he reſided long at her court, and travelled over the greater part of Europe at her expence. He was appointed ſecretary to this queen in 1361, and continued five years in her ſervice; during which period he viſited Scotland, and was entertained for ſome time by William earl of Douglas. In 1366 he was in Gaſcony with Edward the Black Prince, and afterwards viſited ſeveral of the Italian courts. In 1369, he loſt his kind patroneſs Philippa, and retiring to his own country, obtained a benefice in the dioceſe of Cambray. He ſeems however but ill qualified for the office of the cure of ſouls, as well from his love of pleaſure, as from his devotedneſs to hiſtorical reſearch and compoſition. He had already given conſiderable ſpecimens of his poetical talents, and now entered into the ſervice of the duke of Brabant, who was alſo a poet. From the compoſitions of his maſter, joined with ſome of his own, he formed a kind of romance, entitled "Meliador," relating to love and chivalry. After the deceaſe of the duke in 1384, he acquired the patronage of Guy earl of Blois, and travelled to the court of Gaſton earl of Foix, by whom he was received with great cordiality, and who liſtened with intereſt to the recital of his verſes. After ſome other travels he returned home, and continued his hiſtory. In 1395 he viſited England again, and was introduced to Richard II., a young man, by whom he was graciouſly and kindly received, and to whom he had the honour of preſenting a ſplendid copy of his "Meliador."

He returned to his own country, fixed his reſidence at Chimay, where he was appointed canon and treaſurer of the collegiate church. At this place he probably died, for the following verſes are found in the archives of the chapter of St. Monegunda, which are truly characteriſtic of the hiſtorian.

"Gallorum ſublimis honos at fama tuorum,
Hic, Froiſſarde, jaces, ſi modo forte jaces.
Hiſtoriæ vivus ſtuduiſti reddere vitam,
Defuncto vitam reddet at illa tibi."

Though Froiſſart was the author of thirty thouſand verſes, his poetical character is ſunk into oblivion, and he is celebrated only as an hiſtorian. In this capacity he is highly valued by thoſe who ſtudy ancient manners from original drafts.

His Chronicle, which is divided into four books, comprehends the period between 1326 and 1400, and it relates the events which took place not only in France, but in Flanders, Scotland, and Ireland, with numerous details reſpecting the papal courts of Rome and Avignon, and collateral particulars of the tranſactions in the reſt of Europe, in Turkey, and even in Africa. His reputation ſtands high as a faithful and diligent narrator of what he ſaw and heard. By the French he has been charged with groſs partiality towards the Engliſh; they bring againſt him the crime of making Edward, and his ſon, the Black Prince, the heroes of his hiſtory. But it cannot be denied that they were the heroes of the age in which they flouriſhed, and therefore an impartial hiſtorian was obliged to repreſent them in their true colours, and to make them the leading characters of the day. Mr. Johnes, in his edition of Froiſſart's Chronicles, has ſucceſsfully vindicated the character of the hiſtorian from the charge of partiality: throughout the whole work, he ſays, there is an evident diſpoſition to give praiſe to valour on whatever ſide it was employed. The hiſtorian mourns over the death of each valiant knight, exults in the ſucceſs of every hardy enterprize, and ſeems carried away almoſt by his chivalrous feelings, independently of party conſiderations. Till the publication of Mr. Johnes's tranſlation, the beſt edition of the "Chronicles" was that of Lyons in four volumes folio, 1559. The Engliſh reader is referred to Mr. Johnes's octavo edition of the Chronicle for farther particulars concerning Froiſſart: but in the "Memoirs of the Academy of Inſcriptions" there are many curious and intereſting particulars relative to his life and writings. Moreri. Johnes's edition of the Chronicles of England, France, &c. 8vo. 1805.

FROISSY, in *Geography*, a town of France, in the department of the Oiſe, and chief place of a canton in the diſtrict of Clermont; 5 miles S.S.W. of Breteuil. The place contains 663, and the canton 11,234 inhabitants, on a territory of 180 kiliometres, in 23 communes.

FROITZHEIM, a town of France, in the department of the Roer, and chief place of a canton in the diſtrict of Aix-la-Chapelle. The place contains 384, and the canton 8,156 inhabitants, in 30 communes.

FROLOIS, a town of France, in the department of the Côte d'Or; 21 miles N.W. of Dijon.

FROMAIL, a town of Walachia; 15 miles N.E. of Buchareſt.

FROMAGE, Peter, in *Biography*, diſtinguiſhed for his great exertions among the Catholic miſſionaries in the Eaſt, was born at Laon in the year 1678. In 1693 he entered the order of the Jeſuits, and on account of his ſubſequent proficiency he was ſelected by his ſuperiors to preſide over the claſſical ſtudies of their younger pupils. Having completed his theological courſe, he offered his ſervices as a miſſionary to the Levant; being approved, he was firſt ſent into Egypt, where he exerted all his powers in acquiring a knowledge of the Arabic language, nor was he leſs zealous in performing the duties attached to his different employments. He was afterwards ſent into Syria, where he ſpent the remainder of his life. Here he eſtabliſhed a printing preſs for the Arabic language, in the monaſtery of St. John, near Antura, a village in the chain of mountains diſtinguiſhed by the name of Anti-Libanus. Having procured the neceſſary types from Rome, he printed in Arabic a great number of theological and devotional pieces, which he took care to diſperſe through the country. Fromage was preſent at a ſynod of the Maronites held in 1736, and pronounced a diſcourſe at its opening, which is publiſhed with an account of the proceedings of the ſynod in the eighth volume of the "New Memoirs of the Miſſions of the Society of Jeſus in the Levant." Fromage died in the year 1740. Moreri.

FROME, in *Geography*, a river of England, in the county of Somerſet, which joins the Avon about 5 miles S.E. of Bath.—Alſo, a river of England, which runs into the Lug, near Hereford.—Alſo, a river of England, in the county of Dorſet, which paſſes by Dorcheſter, &c. and runs into the ſea in Poole harbour, a little below Wareham.—Alſo, a river of England, in the county of Glouceſter, which joins the Avon at Briſtol.—Alſo, a river of England, which runs into the Severn near Berkeley, in Glouceſterſhire.

Frome, or *Frome Selwood*, a large town in the hundred of Frome, Somerſetſhire, derives its firſt denomination from being ſituated on a river of that name, which riſing to the ſouth of the place, paſſes through it, takes a northerly direction, and falls into the Briſtol Avon, below Bradford, in the county of Wilts. The additional appellation it receives from the diſtrict which formerly conſtituted the extenſive and celebrated foreſt of Selwood. Leland deſcribes it as ſtanding upon the cliff of a ſtony hill, which is partially correct; for it is pleaſantly ſeated upon ſeveral abrupt hills, and at the bottom of one is the principal entrance by a good ſtone bridge of five arches over the river. The church is a handſome and ſpacious ſtructure, compriſing a nave, chancel, north and ſouth aiſles, chancel and four chapels, with a large ſquare embattled tower, ſurmounted by an octagonal ſpire, riſing 120 feet in height. Here are alſo ſix other places of worſhip for various denominations of proteſtant diſſenters. Near the bridge is a good free ſchool, and an alms-houſe for poor widows, erected by ſubſcription in 1720. Anciently in this pariſh a monaſtery was erected by Aldhelm, a monk, and biſhop of Sherborne; and ſubſequently a priory and nunnery, no veſtiges of which remain.

The town has greatly increaſed within a century paſt, and contains about 38 ſtreets, which are in general narrow, irregularly built of rough ſtones, and covered with heavy ſtone tile, dug in the adjacent quarries. By the returns made to parliament it appears that, in 1801, the town included 1653 houſes, and 8,748 inhabitants. But this eſtimate is glaringly defective. In 1724 it was conſidered as having more inhabitants than the city of Bath; and though it has not increaſed like that place of faſhionable reſort, yet, upon a moderate computation, one-third may be added to the number in the official return. Theſe are principally employed in the manufacturing of ſuperfine cloths and kerſeymeres, or in other branches of buſineſs connected with this ſtaple manufacture: the river affording facilities to the trade for the purpoſes of ſcouring, dying, erecting fulling and gig-mills, with other kinds of machinery. Frome was formerly governed by a bailiff, but at preſent the police is under the direction of the neighbouring magiſtrates, aided by two conſtables, annually choſen at the courts leet of the joint lords of the manor, the marquis of Bath, and the earl of Cork and Upper Oſſory. The latter nobleman has an elegant

ſeat at Marſton park, in the adjoining pariſh, and the country is embelliſhed with ſeveral handſome manſions in the vicinity. See Collinſon's Hiſtory of Somerſetſhire.

FROMERIES, a town of France, in the department of the Somme; 7 miles S.W. of Poix.

FROMIGUERE, a town of France, in the department of the Eaſt Pyrenees; 7 miles N. of Montlouis.

FROMISTA, a town of Spain, in the province of Leon; 18 miles N. of Palencia.

FROND, in *Botany*, (*Frons*, a leafy bough,) is a kind of ſtem which is at the ſame time a leaf, and bears the fructification. (See Caulis and Fructification.) The term is excluſively appropriated to plants of the claſs *Cryptogamia*. Sprengel, in his letters on Cryptogamous Plants, ſeems not to have been aware of this, when he objects to its uſe, becauſe ſeveral plants of the other claſſes bear their flowers on the leaf. Such indeed is the caſe in *Ruſcus*, *Phyllanthus*, *Xylophylla*, &c.; and even in *Turnera*, where the flower proceeds from the leaf-ſtalk. But theſe examples do not prove the impropriety of the term in Cryptogamous plants, to which alone it is now applied. The fern tribe, (ſee Filices,) are good examples of a frond, as each plant conſiſts of a ſtalked leaf, bearing the fructification either on its back, or in ſpikes or cluſters, which are evidently a metamorphoſis of ſome of its parts or lobes. Lichens alſo have a true frond, either in the form of a cruſt, a leathery leafy expanſion, or a branched ſhrubby ſubſtance, with each of which the fructification is intimately connected. Linnæus has erroneouſly uſed the term *frons* in the natural order of *Palmæ*, which, however lofty in their growth, have not the proper ſtem of a tree, but are genuine herbaceous plants, whoſe ſtalks or ſtems, not their leaves, bear the fructification, neither do they belong to the claſs *Cryptogamia*. This great obſerver is however thus far juſtified, that the depoſition of wood in palms is exactly like that of ferns, and betrays a ſtrong and peculiar affinity between them. Palms indeed are the connecting link between Ferns and the Liliaceous order.

FRONDES. See Leaf.

FRONDESCANTIA denotes the ſeaſon of the year when the leaves of plants are unfolded.

FRONSAC, in *Geography*, a town of France, in the department of the Gironde, and chief place of a canton, in the diſtrict of Libourne, ſeated on the Ille; two miles N. W. of Libourne. The place contains 1339, and the canton 13,348 inhabitants, on a territory of 165 kiliometres, in 22 communes. The fruitful tract at the junction of the Ille and Dordogne, oppoſite to Libourne, on which this town is ſituated, is called *Fronſaides*.

FRONT, the forehead, or that part of the face above the eye-brows.

The word is formed of the Latin *frons*; and that from the Greek φρονειν, *to think*, *perceive*; of φρην, *mens*, *the mind*, *thought*. Martinius, to make out this etymology, obſerves, that from the forehead of a perſon we perceive what he is, what he is capable of, and what he thinks of. Du Laurens chuſes to derive it from *ferre*, becauſe it bears the marks of what we have in our head.

Front is alſo uſed where ſeveral perſons, or things, are ranged ſide by ſide, and ſhew their front, or foreparts.

Front, in *Architecture*. The elevation of any of the exterior ſides of the walls of a building is denominated a front. Buildings being generally conſtructed of a rectangular form, have four fronts; the one that is beſt finiſhed is called the principal front, which is generally that through which the building is entered; and on this account is alſo called the entrance front. The oppoſite front to the entrance is called the rear front; and the fronts on the ſides are denominated flanks, which, in towns where the houſes join each other, are called party-walls.

Front, in *Fortification*. See Face and Tenaille.

Front *of a Regiment*, in *Military Language*, denotes the foremoſt rank of a battalion, ſquadron, or any other body of men.

To front every way, is when the men are faced to all ſides. See File-*leaders*.

Front *of a Camp* is the line that determines its extent, and in which are placed the colours and ſtandards of the troops that occupy the *camp*; which ſee.

Front, in *Perſpective*, a projection or repreſentation of the face, or fore-part of an object, or of that part directly oppoſite to the eye; called alſo, and more uſually, orthography.

Front, *Line of the*. See Line.

Front *Scale*. See Scale.

Front *Royal*, in *Geography*, a town of America, in Frederick county, Virginia, at the foot of the Blue Ridge, eight miles E. of Shenandoah river, and 20 miles S. of Winchester. It contains about 90 houſes, a Preſbyterian church, and another for Methodiſts. A reſpectable German ſchool is kept here.

FRONTAL, in *Architecture*, a little fronton or pediment, ſometimes placed over a ſmall door or window.

Frontal, *Frontlet*, or *Brow-band*, is alſo uſed in ſpeaking of the Jewiſh ceremonies.

This frontal conſiſts of four ſeveral pieces of vellum, on each whereof is written ſome text of ſcripture; they are all laid on a piece of black calf's leather, with thongs to tie it by. The Jews apply the leather with the vellum on their foreheads in the ſynagogue, and tie it round the head with the thongs.

FRONTALE Os, in *Anatomy*. See *Os* Frontis.

Frontale, or *Frontal*, in *Medicine*, an external form of remedy, applied on the forehead and temples with a bandage, for the cure of the head-ache, megrim, vapours, defluxions on the eyes, &c. Frontals are compoſed of roſes, elder flowers, betony, marjoram, lavender, camphire, &c. wrapped in a linen cloth, and applied over the forehead and temples.

There are alſo frontals, in manner of liniments, made of unguentum populeum and extract of opium, or of paſtes, powders, ſeeds, &c.

In frontals applied to eaſe the violence of the head-ache, in the heights of fevers, they frequently mix the kernels of cherries.

FRONTALIS, in *Anatomy*, a name given to ſeveral parts ſituated about the frontal bone; as two hollows in the ſubſtance of the bone, a nerve, an artery, and a vein.

FRONTANA, in *Geography*, a town of Spain, in Catalonia; 25 miles S. E. of Urgel.

FRONTATED, a term uſed by *Botaniſts* to expreſs that the petalum, or leaf of a flower, grows broader and broader, and at laſt, perhaps, terminates in a right line, in oppoſition to *cuſpidated*, which expreſſes that the leaves terminate in a point.

FRONTE, in *Geography*, a town of France, in the department of the Po, on the Marlon; 11 miles N. of Turin.

FRONTEAU, John, in *Biography*, was born at Angers in the year 1614, and was educated by a pariſh prieſt in that neighbourhood, by whoſe inſtructions he profited ſo well, that before he was thirteen years of age he could, with the utmoſt

utmoſt facility, tranſlate his native language into the Latin and Greek. At the college of La Fleche he went through a courſe of philoſophy and his other advanced ſtudies, and in the year 1631 he took the habit of a canon regular in the houſe of All Saints at Angers. At St. Genevieve, in Paris, he was appointed to teach philoſophy, and in 1639 was appointed profeſſor of divinity, which he taught with high reputation for 12 years. In 1648 he was appointed chancellor of the univerſity of Paris, and obtained other valuable church preferments. He once incurred the diſpleaſure of the court on ſuſpicion of being a defender of, and attached to the Janſeniſts; but his ſubſequent conduct, and his readineſs to ſign the required teſt, raiſed him again into favour. He died in 1662, not many days after he was inducted into the priory of St. Magdalen of Montargis. He was author of many learned works, and a collection of his letters was publiſhed after his death. He was an able and diligent ſcholar; beſides the Latin and Greek languages, he was maſter of moſt of the modern, and all the oriental tongues. "He kept up," ſays Du Pin, "a large correſpondence, not only with the learned, but alſo with the moſt conſiderable perſons in the kingdom, and particularly with the moſt conſiderable men of the long robe, who honoured him with their friendſhip. In his works he knew how to adorn his profane reading by the eccleſiaſtical, and always enlivened the ſubject with ſome paſſages of the fathers, or with ſome curious hiſtorical notes and obſervations." Moreri. Du Pin.

FRONTEIRA, in *Geography*, a town of Portugal, in the province of Alentejo; ten miles N. of Eſtremos.

FRONTEITTEN, a town of Germany, in the duchy of Stiria; 14 miles N. N. W. of Gratz.

FRONTENHAUSEN, a town of Bavaria; 14 miles E. of Landſhut.

FRONTEVAUX, *Order of*. See FONTEVRAUD.

FRONTIER, the border, confine, or extreme of a kingdom, or province; which the enemies find in front, when they would enter the ſame. Thus we ſay, a frontier town, frontier province, &c. Frontiers were anciently called *marches*.

The word is derived from the French *frontiere*, and that of the Latin *frontaria*; as being a kind of front oppoſed to the enemy. Skinner derives frontier from *front*; inaſmuch as the frontier is the exterior, and moſt advanced part of a ſtate; as the front is that of the face of a man.

FRONTIGNAN, in *Geography*, a town of France, in the department of the Herault, and chief place of a canton in the diſtrict of Montpellier; 12 miles S.W. of Montpellier. This little town is ſituated on lake Maguellone, called alſo lake Thau, and is famous for its wine, generally called Frontigniac. The place contains 1,420, and the canton 3,032 inhabitants, on a territory of 205 kiliometres, in five communes.

FRONTIGNIAC WINE, is ſo called from a town of Languedoc, in France, mentioned in the preceding article, remarkable for producing it.

FRONTINAC, in *Geography*, a county of Upper Canada, bounded on the E. by the county of Leeds, on the S. by lake Ontario, on the W. by the townſhip of Erneſt, running N. 24° W. until it interſects the Ottawa or Grand river, and thence deſcending that river until it meets the northweſternmoſt boundary of the county of Leeds.

FRONTINAC, *Fort*, a fortreſs in Canada, at the head of a fine bay or harbour, on the N.W. ſide of the outlet of lake Ontario, where veſſels of all ſorts may ride in ſafety. It is a league from the mouth of the lake, and at a ſhort diſtance S. of Kingſton, and about 300 miles from Quebec. The ſoil is ſo well cultivated about this place as to produce all ſorts of European and Indian corn and fruits. See ONTARIO.

FRONTINUS, SEXTUS-JULIUS, in *Biography*, an eminent Roman, and city prætor A.D. 70. He was afterwards a ſupplementary conſul, and diſtinguiſhed himſelf by his military talents as a commander in Britain. He is noticed by the younger Pliny and other writers for the benefit which his country derived from his talents. Under the emperor Nerva he was appointed to the ſuperintendance of the waters, and in this capacity he brought the water of the Anio to Rome by means of a ſplendid aqueduct. He wrote two books on the conſtruction of theſe works, by the emperor's expreſs order. He wrote likewiſe upon military ſtratagems, a work which is ſtill extant. The beſt edition of his works is that printed at Lyons 1731 and 1779. A work on agriculture, which has been aſcribed to him, was probably compoſed by a later writer. When Frontinus died he forbade the erection of a monument to his memory, ſaying that it was a ſuperfluous expence; for his name would live if he had done any thing to merit the honour. Gen. Biog.

FRONTIS, Os, in *Anatomy*, one of the bones of the head. See CRANIUM.

FRONTISPIECE, in *Architecture*, the portrait or principal face of a fine building.

The word is formed of the Latin *frontiſpicium*, q. d. *frontis hominis inſpectio*.

The frontiſpiece of the Louvre is the fineſt piece of architecture in France.

Hence, alſo, by a figure, we ſay, the frontiſpiece of a book, meaning an ornament, with an engraven title on the firſt page.

FRONTLET. See FRONTAL.

FRONTLET *Aim*, in *Gunnery*, is a piece of a plank three inches thick, a foot long, and ſeven or eight inches high, with a round cavity underneath to fit the outſide of the gun, and having a ſmall ſlit to ſee the object through it. It is placed upon the vent field of the gun, when it is pointed in a battery.

FRONTON, in *Architecture*, a French word uſed to expreſs an ornament over a door or a pediment. See PEDIMENT.

FRONTON, in *Geography*, a town of France, in the department of the Upper Garonne, and chief place of a canton in the diſtrict of Toulouſe; 15 miles N. of Toulouſe. The place contains 2,149, and the canton 11,708 inhabitants, on a territory of 247½ kiliometres, in 20 communes.

FROOGARDE, a town of Norway, in the dioceſe of Drontheim; 60 miles S.S.E. of Drontheim.

FROOKABOO, a town of Africa, in Bambarra. N. lat. 12° 45'. W. long. 5° 20'.

FROSASCO, a town of Italy, in the department of the Po; 13 miles S.W. of Turin.

FROSCHGRUN, a town of Germany, in the principality of Culmbach; 5 miles S.E. of Lichtenberg.

FROSCHIUS, JOHN, in *Biography*, a doctor in theology, and a prior of the order of Carmelites, at Augſburg; publiſhed in 1535 a treatiſe, entitled "Rerum Muſicarum Opuſculum rarum ac inſigne, totius ejus negotii rationem mira induſtria et brevitate complectens, jam recens publicatum, Joan Froſchio autore." Argentorati, 1535.

This work is divided into nineteen chapters, of which the firſt fourteen are chiefly employed in diviſions of the ſcale and theory of ſound, according to the doctrines of the ancients. Chap. 15. explains the notes in uſe during the early part of the ſixteenth century, as placed on lines and ſpaces; the

the characters for time and their proportions; perfection, imperfection, prolation, &c. There is but one chapter, the nineteenth and the laſt, on the ſubject of compoſition, or the practice of harmony. The work is terminated with examples of counterpoint in four and ſix parts; but being printed ſeparately, in old notation, and not regularly barred, they are ſomewhat difficult to ſcore.

FROSE, in *Geography*, a town of Germany, in the duchy of Magdeburg; 10 miles S. of Magdeburg

FROSO, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 63 34'. E. long. 22 14'.

FROSON, a town of Sweden, in Jamtland, ſituated in an iſland in lake Storſio, containing a ſchool and poſt-office. N. lat. 63° 10'. E. long. 15°.

FROSSAY, a town of France, in the department of the Lower Loire; 4 miles S.E. of Painbœuf.

FROST, in *Meteorology*, ſignifies that ſtate of the atmoſphere in which the thermometer is below 32°, and water becomes congealed.

When the ſun paſſes to the ſouth of the equator, the northern hemiſphere gradually loſes of its temperature, its expenditure of heat being greater than the ſupply. After ſome time a rapid diminution of temperature is obſerved as we paſs over the ſucceſſive parallels of latitude from the equator to the North pole. As far as the action of the ſun's rays is concerned, this decreaſe of temperature ſhould be regular; that is, it ſhould be in ſome proportion to the diſtance from the equator, and to the progreſs of the ſeaſon. We find however from experience, that ſuch regularity does not take place. In any given northern latitude the temperature is more eſpecially deſultory in the winter ſeaſon. Some other cauſe therefore muſt operate to produce this irregularity. This cauſe is the winds. Not only are the winds more violent in the winter ſeaſon, but they induce a greater change of temperature, all other circumſtances the ſame, than in any other ſeaſon, by reaſon of the contiguous climates being then more diſproportionate than uſual in their temperature. See WIND and TEMPERATURE.

Mr. Kirwan remarks, that "it ſcarce ever freezes in latitudes under 35°, unleſs in very elevated ſituations." It is known indeed, that ice and ſnow are perpetual, even under the equator; but then it is in very elevated and almoſt inacceſſible ſituations. Above the latitude of 35°, froſt is gradually more prevalent in the winter ſeaſon, as we approach the pole. In Britain, froſt commonly appears in the courſe of October and diſappears in April; but the ſeverity of it is confined to December, January, and February. Such however is the uncertainty of froſt in this country, that ſome winters paſs over with ſcarcely a week of keen froſt, and the thermometer never lower than 20°; whilſt in other winters we have 10 or 12 weeks of froſt with little interruption, and the thermometer ſometimes as low as the zero of Fahrenheit, or lower. This difference of ſeaſons ariſes from the wind being accidentally confined principally to the S.W. or to the N.E. direction, the former current coming from the equatorial, and the latter from the polar regions. It is obſervable that Britain, from its inſular ſituation, is leſs liable to extreme cold than the correſponding latitudes on the continent; but then its temperature is probably more fluctuating.

There are certain phenomena attending the natural congelation of water in ordinary froſts that deſerve notice. Small portions of water, inſulated, or cut off from the ſurface of the ground, are moſt liable to be frozen. Becauſe the ground is comparatively a good conductor of heat, no body in contact with it can be frozen till the temperature is reduced all around. Air is generally the medium that poſſeſſes the freezing temperature; therefore the more completely any body is ſurrounded with air, and the leſs the connection it has with the earth, the more readily it is frozen. Ice is formed firſt over ſhallow pools of water, then over ponds, and laſtly over lakes. The reaſons are various. Earth has a leſs capacity for heat than water; it is therefore ſoon reduced and deprived of the heat which it ſhould impart to the water in the firſt caſe. But in deep waters the tardy congelation is principally owing to another cauſe, in combination however with the former. Water is a liquid which increaſes in ſpecific gravity as its temperature diminiſhes down to 36°. Now as it muſt be cooled to 32° before it can freeze, it follows that the cooling of water at its ſurface cannot effect its congelation till the whole maſs is made to approximate the freezing temperature; becauſe the cooled water immediately tends downwards, and warmer water aſcends.

Another reaſon for the ſlow congelation of water is quite of a different kind from thoſe already mentioned. It is a change of capacity of the water for heat. During congelation water loſes as much heat as would, if added, be ſufficient to raiſe its temperature 140°. Of courſe it requires a long continued application of a cooling cauſe to deprive the water of ſo much heat. This fact was diſcovered by Dr. Black; he called the heat ſo diſengaged *latent*, becauſe it did not affect the thermometer. The importance of this change of capacity of water in checking the ſeverity of winter, has been well elucidated by different authors, particularly by Crawford in his Eſſay on Animal Heat, and by count Rumford in one of his Eſſays on heat.

Springs of water are obſerved to remain unfrozen for a great length of time, and to emit a ſmoke or vapour. This is owing to their riſing from a great depth, and conſequently partaking of the internal temperature, which is nearly uniform throughout the year, and the mean annual temperature. The water, comparatively warm, ſends off ſteam, which the cold air ſoon condenſes into a miſt. See EVAPORATION and FOG.

Froſt does not penetrate ſo deep into the ground as might be expected. In Britain it ſeldom ſinks 10 or 12 inches; though in a very long froſt it has been found 18 inches deep or more. In high northern latitudes, where the cold is more ſevere, it does not penetrate proportionally; the reaſon is, the ground is generally covered with ſnow, which defends it from the action of the air. See SNOW.

The force with which water expands in the act of freezing is wonderful. Very ſtrong veſſels have been burſt by the freezing of water within them. Mr. Boyle relates that a gun-barrel filled with water, then cloſed and frozen, was burſt the whole length. By a ſimilar experiment Huygens burſt a cannon. Major Williams made many experiments on the expanſive force of freezing water at Quebec in 1784 and 1785. He filled iron bomb-ſhells of various ſizes with water, then plugged the fuze-hole cloſe up, and expoſed them to a ſtrong froſt. The plugs were always thrown out with force, ſometimes to the diſtance of 400 or 500 feet, or the ſhells burſt, the ice at the ſame time bolting out. Hence the effects of froſt in ſplitting rocks, burſting pipes, &c. are not ſo much to be wondered at.

In ſome countries, particularly Ruſſia, meat is preſerved for ſeveral months by means of froſt.

A chronological record of ſome of the moſt remarkable froſts is ſubjoined. See Hutton's Math. and Philoſ. Dict.

In the Year

220. Froſt in Britain that laſted 5 months.
250. The Thames frozen 9 weeks.
291. Moſt rivers in Britain frozen 6 weeks.
359. Severe froſt in Scotland for 14 weeks.

In the Year

508. The rivers in Britain frozen for two months.
558. The Danube quite frozen over.
695. The Thames frozen 6 weeks; booths built on it.
759. Froſt from October 1ſt, till February 26th, 760.
827. Froſt in England for 9 weeks.
859. Carriages uſed on the Adriatic ſea.
908. Moſt rivers in England frozen 2 months.
923. The Thames frozen 13 weeks.
987. Froſt laſted 120 days; began December 22d.
998. The Thames frozen 5 weeks.
1035. Severe froſt on June 24th; the corn and fruits deſtroyed.
1063. The Thames frozen 14 weeks.
1076. Froſt in England from November till April.
1114. Several wooden bridges carried away by ice.
1205. Froſt from January 14th till March 22d.
1407. Froſt that laſted 15 weeks.
1434. From November 24th to February 10th, Thames frozen down to Graveſend.
1683. Froſt for 13 weeks.
1708-9. Severe froſt for many weeks.
1715. The ſame for many weeks.
1739. One for 9 weeks; began December 24th.
1742. Severe froſt for many weeks.
1747. Severe froſt in Ruſſia.
1754. Severe one in England.
1760. The ſame in Germany.
1776. The ſame in England.
1788. Thames frozen below bridge; booths on it.
1795. Severe froſt in England.

Frost, in *Phyſiology*, or as it regards the animal and vegetable kingdoms, is of great conſideration. Clear froſty weather is accounted ſalubrious, when the cold is not extreme, and a due portion of exerciſe is taken. Extreme cold is ſometimes known to freeze the parts of the body expoſed. Loſs of ſenſation in the parts is the conſequence, and if not ſpeedily attended to, mortification enſues. Rubbing the affected parts with ſnow is ſaid to be the beſt remedy. It is remarkable that perſons expoſed to great cold are ſtrongly inclined to ſleep; this ſymptom therefore ſhould be conſidered as alarming, and due care ſhould be taken by keeping the fatal conſequence in view.

Frost, in *Agriculture* and *Gardening*, is beneficial in the winter ſeaſon. It expands the ſoil, renders it more looſe and friable, and adapts it for tillage; it deſtroys grubs and other inſects which are injurious to vegetation. On the other hand, in an early ſpring, when vegetation has advanced too rapidly, the effects of froſt have ſometimes been highly deleterious. What are called *blights* are moſt frequently occaſioned by froſt. It often happens, that warm weather in April and May is accompanied with thunder, and this is ſucceeded by a week or two of cold froſty weather. After ſome nights more ſeverely cold, when the thermometer has been at or near freezing, the blight appears. It has been aſcribed in ſuch caſes to the lightning; but it is clearly an effect from an oppoſite cauſe. Experienced gardeners inform us that the beſt remedy for blights in vegetation, ſuch for inſtance as in the young ſhoots of potatoes, is to cut off the part affected, which otherwiſe, like a gangrene, ſpreads the diſorganization. See Blight.

Frost, *Hoar*, is the dew frozen on the graſs, on trees, or on the ſurface of any other body. This phenomenon, which is conſtantly obſervable in froſty weather, is notwithſtanding more particularly an object of notice in autumn. The reaſon is, it is more abundant then, and frequently unaccompanied with other ſigns of froſt, as ice and ſnow. Vapour at that ſeaſon is copious, and dews ſtrong. The cold is not yet ſufficiently powerful to freeze a body of water in contact with the earth; but the dew, being ſmall drops of water inſulated, or reſting lightly on the graſs, requires leſs cold to congeal it. There is a remarkable appearance of hoar-froſt when a thaw commences after a long froſt. Houſes, walls, &c. which during the froſt ſeemed unaffected, are ſuddenly covered with a thick coating of hoar-froſt. It is the walls, which retaining the previous temperature for ſome time, condenſe the vapour introduced by the thaw into hoar-froſt.

Frost, *Effects of, on Land, Plants, Trees*, &c. The operation of freezing is found to have conſiderable effects not only in breaking down, reducing, and mellowing the particles of ſtiff, adheſive, heavy ſoils, but alſo on the juices, fruits, and other parts of plants and trees.

It is conſequently obvious, that wherever lands are of an obſtinate, harſh, ſtiff, clayey quality, much advantage may be derived from the practice of laying them up in ridges, in order that they may be expoſed to the action and influence of froſt during the winter ſeaſon. The work of ploughing them up ſhould be performed late in the autumnal ſeaſon, juſt before the froſt uſually ſets in, that they may afford their fulleſt effects. In many caſes a fine tilth may be obtained in this way without any ſpring ploughing, the ground being merely reduced by the ſcuffler at the time of putting in the ſeed, which is a great ſaving of both labour and expence.

The action of froſt is ſeldom much wanted on the light, ſandy friable ſoils, as it may render them too open and porous for producing good crops, and thereby do great miſchief. It is very ſeldom that corn crops are in any way injured by hard winters, eſpecially where the land has been perfectly drained, and is in any degree covered with ſnow. But they are highly deſtructive of great numbers of different kinds of inſects, grubs, and other ſorts of vermin; while, at the ſame time, by leaving the earth in a fine, looſe, powdery ſtate, they fit it in the beſt manner for the ſpreading of the roots, by which, as the warmth of the ſpring approaches, ſtrong healthy plants are produced, and of courſe abundant crops. On the contrary, when frequent rain falls in the winter ſeaſon without froſt, the earth is ſoddened, ſo as to produce afterwards little or nothing of good grain, but plenty of blades, which are liable to be ſoon deſtroyed by the hoar froſts of the ſpring, by inſects, or by the choaking of weeds; or which, if they eſcape, yield ſtraw in the place of grain.

The caſe in which the greateſt danger is to be apprehended from froſt, is where the ground is inclined to be wet, and where there is no covering of ſnow upon it. For inſtance, where a ſharp froſt ſets in after a ſudden thaw, the fibres of the roots are liable to be burſt or broken by the expanſion which is produced by the too abundant moiſture of the plants, and perhaps that which ſurrounds them.

Froſt is found to have much power in the ripening of grain and fruits of different kinds. It has been ſtated by the author of "Minutes of Agriculture," for the year 1785, that the barley had not ripened perceptibly for ſome weeks before the ſharp froſts, ſince which it has ripened daily. There are, it is continued, twice the number of ripe ears now there were a week ago; they are not only changed as to colour, but the corn is obviouſly plumper. Before the froſts, the heads ſeemed ſlender and puny; ſo much ſo, that he had conſigned the whole to the miller; now he begins to hope that ſome of it may, this year of ſcarcity, be fit for the maltſter. And it is added, that it was a general obſervation in this country, that in the ſame year, (a wet backward

backward ſummer,) the late ripe crops did not ripen until froſt came; even wheat was out in December. It is aſked, how this is to be explained? Froſt can, it is ſuppoſed ſcarcely to be doubted, compreſs the ſap-veſſels of vegetables, and probably force the ſap out of them back to the earth, as is commonly ſuppoſed; but perhaps the natural receptacles of the plants are firſt ſupplied. It is readily obſervable, that fruits ripen, leaves fall, and that lattermath ſhrinks by the action of froſt.

And it has been noticed by Dr. Darwin, that the ripening of fruit and ſeed is often delayed from the want of a due evaporation of their perſpirable matter, and that of ſolar light in cloudy weather; hence, in the northern parts of the iſland, the oats are found to ſeldom ripen before the froſt commences, with the dry ſeaſon that uſually attends it.

Though the effects of froſts on trees and other vegetable productions have long been known, the differences between ſuch as take place in ſevere winters, and thoſe which happen in the mornings during the ſpring ſeaſon, were never fully underſtood, till explained in the Memoirs of the Academy at Paris by M. Du Hamel, and M. De Buffon.

The froſts of ſevere winters have been found much more powerful in deſtroying all ſorts of tender vegetable productions, though they occur much more rarely, than thoſe of the ſpring, which are, nevertheleſs, very injurious, by the conſtancy and frequency of their happening. The principal difference with reſpect to trees is, that the froſts of ſevere winters affect the wood of the trunks and large branches, while thoſe of the ſpring are chiefly hurtful to the buds and other tender parts.

Beſides, the common winter froſts taking place at a time of the year when moſt of the trees in woods and other places have neither leaves, flowers, nor fruits upon them, and when their buds are in ſuch a ſtate of torpor as not to be eaſily injured, eſpecially when the preceding ſummer has not been over-moiſt, they ſeldom, under common circumſtances, prove in any high degree deſtructive to them. It is only the ſevere froſts that happen late in the winter that do great miſchief, even to ſuch trees as they do not wholly deſtroy. The injuries which trees are ſtated to receive in this way are, long cracks in the direction of the fibres, portions of dead wood incloſed by ſuch as is yet in a living ſtate, and that affection which is known to woodmen under the title of the double blea, which is a perfect circle of blue or ſoft white wood, that, when the tree is afterwards cut down, is found to be covered by a circle of hard ſolid wood.

The blea, in its natural ſtate, is an outer circle of white and imperfect wood encompaſſing the hard and more perfect wood of the tree, and ſurrounded by the bark, being eaſily diſtinguiſhed in moſt ſpecies from the hard wood or heart of the tree, by its different colour, and want of hardneſs or ſolidity. See ALBUMEN.

The celebrated M. Reaumur made long ſince a great number of obſervations on the blea in trees of different parts of France, all which tended to ſhew the falſe blea under the ſame number of annual circles of the after-growth of the trees, which, on being counted, proved exactly as many as the number of years ſince 1709; whence he naturally concluded, that all the falſe blea he found throughout the kingdom was the effect of the ſeverity of this one hard winter.

It is alſo further ſuppoſed evident, that this falſe blea is that part of the tree which, in the above year, was the true and natural blea, and which the ſeverity of the froſts of that winter prevented from ever becoming ſound and ſolid wood, leaving it to become more weak and defective for a ſucceſſion of years; during which the ſeveral annual circles of ſupervening blea all became ſound and perfect wood in their natural courſe. And it is ſufficiently obvious, that the blea muſt be that part of the wood which is moſt expoſed to ſuffer, in conſequence of its being the outer wood of all, and that which forms a covering for the inner part. It may likewiſe be added, that it is naturally of a much leſs compact texture, and is much more replete with juices for the froſt to exert its action upon.

The ſplitting of trees in the direction of their fibres often takes place with a very loud crack or report. It is far from being uncommon in large foreſts to meet with trees that have ſuffered in this way, and which having outlived the ſeverity of the winter's froſt that produced them, are found to have a long ſort of ridges or ribs, marking the places where the cracks originally were, and forming a kind of cicatrices or ſcars over them. Theſe cicatrices or ribs are, however, only ſuperficial, as wherever they are, the cracks are ſtill found remaining under them in the trees; for though the bark and blea can unite and conſolidate in this manner, ſo as to conſtitute coverings for them, the fibres of the ſolid wood, when once broken and ſeparated, never cloſe again. Woodmen are moſtly of opinion, that all ſuch cracks in timber are produced by froſts; and it is eaſy to conceive this to be the caſe from the conſideration of the vaſt expanſive form which they cauſe in all frozen liquids. See FREEZING.

It is not, however, by any means aſcertained, that all the different cracks in trees of the timber kind are the effects of froſt: it is not improbable but that ſome of them may depend upon other cauſes, as a redundance of ſap, &c.

With reſpect to the difference of the expoſures of trees, in regard to the effects of froſt, there has been a variety of opinions held forth, but probably without having any foundation in juſt obſervation. A great number of perſons ſuppoſe that the effects of froſt are the more ſevere on ſuch as have a northern expoſure, while others imagine a ſouthern or weſtern aſpect to be the moſt powerfully affected by it. There can be little doubt but that northern expoſures are the moſt cold; but ſtill it is not to be concluded, that the effects of froſts on trees, in ſuch aſpects, are the greateſt and moſt injurious to them; on the contrary, there are numerous proofs that ſhew it to be on the ſouthern ſides that trees in general are the moſt cut and injured by them; and it is well known, from repeated trials, that there are particular accidents or conditions under which a more moderate froſt may do greater injury to trees and other vegetables, than the moſt ſevere one that may happen to them, when under more favourable circumſtances.

Early peas, and ſome other forward crops, are frequently, in moſt ſituations, the moſt expoſed to danger, where they have eaſtern expoſures, and where there are alternate froſts and thaws, as the winds from that quarter are apt, in ſuch caſes, to bring with them a portion of muriatic acid, which readily turns the crops black, and wholly deſtroys them.

It was alſo found from the reports of the injuries which trees received during the ſevere froſts of the year 1709, that they were by far the greateſt where repeated falſe thaws took place and were ſucceeded by a repetition of new froſts. And ſpring froſts alſo afford numerous inſtances of the ſame thing. The experiments of M. de Buffon likewiſe inconteſtibly ſhew, that it is not the ſevereſt cold, or the moſt fixed froſt that proves the moſt injurious to vegetable productions. This, however contrary to the commonly received opinion, is not by any means the leſs true or leſs conſiſtent with reaſon. It has been found by numerous experiments

that it is principally humidity that renders froſt ſo fatal and deſtructive to vegetables; conſequently, every thing that has a tendency to produce this ſtate in them muſt neceſſarily expoſe them to its injurious effects; while ſuch things as can prevent, or take off, an over proportion of moiſture in them, as every thing that has the tendency of drying them, whatever the increaſed degree of cold produced may be, muſt prevent or preſerve them from its injurious influence and operation. There is a variety of facts that tend to prove this. It is well known that vegetables conſtantly experience the effects of froſt, the moſt ſeverely in low, damp ſituations that are ſubject to fogs. Plants which ſtand by the ſides of rivers are frequently found deſtroyed by ſpring froſts as well as thoſe in autumn, while ſuch of the ſame kinds as ſtand in drier ſituations ſuffer little, if at all, by them. The low and wet parts of foreſts are likewiſe well known to produce worſe wood than the high and ſuch as are drier; and coppice wood in low, moiſt places of common woods, though it may puſh out more vigorouſly at firſt than that of other parts, never comes to ſo good a growth, as the froſts in the ſpring kill theſe early top-ſhoots, and oblige the lower parts of the trees to throw out lateral branches; the ſame thing likewiſe happens, in a higher or lower degree, to ſuch coppice wood as grows under cover of larger trees in foreſts; as in this caſe the vapours, not being carried off either by the ſun or wind, ſtagnate and freeze, deſtroying the young ſhoots in exactly the ſame manner as the fogs and damps of marſhy places. It has been long a common remark with horticulturiſts, that froſt is never hurtful to the late ſhoots of the vine, or to the flower-buds of trees, except when it immediately ſucceeds heavy dews or a long continued rainy ſeaſon, in which caſes it ſeldom or ever fails to do great miſchief, though ever ſo ſlight. The injurious effects of froſt are likewiſe conſtantly found to be more ſevere on the crops in newly cultivated lands, than under the contrary circumſtances, which is probably owing to the greater exhalation of moiſture from the ſurface. Such trees alſo as have been recently cut, are found to ſuffer more than others by the ſpring froſts, in conſequence probably of their ſhooting out more vigorouſly.

It has not unfrequently been remarked that the ſide ſhoots of trees are more liable to periſh by ſpring froſts than thoſe from the tops. Indeed M. de Buffon, who examined this point with great accuracy and minuteneſs, conſtantly found the effects of ſpring froſts to be much greater near the ſurface of the ground than elſewhere. The ſhoots within a foot of it were quickly deſtroyed by them; while thoſe at two or three feet in height bore them far better, and ſuch as were at four feet and upwards often wholly eſcaped unhurt, at the time that the lower ones were completely deſtroyed.

The whole of the facts on this ſubject tends, therefore, to ſhew, that it is not ſo much the ſeverity of froſts that proves injurious to trees and other vegetable productions, as that of their being replete with moiſture at the time it occurs. It is on this principle that the great damages done by ſevere froſts on the ſouth ſide of trees are to be explained, though that ſide may all the while have been expoſed to leſs cold than that of the north. Great injury is often done to the weſtern ſides of trees and plantations, as ſhewn in the Memoirs of the Academy of Sciences at Paris for the year 1737, when after a rain with a weſt wind, that wind turns to the north at ſun-ſet, as is not unfrequently the caſe in ſpring; or when an eaſt wind blows upon a thick fog before the ſun riſes.

Frost-*ſplit*, in *Agriculture*, is a term employed by farmers to denote certain effects of froſt on trees, ſuch for inſtance as thoſe of producing large cracks and fiſſures in their trunks and branches, which render them unfit for ſuch uſes as they would otherwiſe have been ſuitable for, and conſequently greatly deteriorate and leſſen their value as timber. Though it may have been contended by ſome that theſe effects on trees proceed from other cauſes than froſt, there are innumerable well authenticated inſtances of its power, when ſevere, of injuring the ſtrongeſt trees in this way. And there can be little doubt, when its very powerful expanſive action is conſidered, of ſuch rents and cracks really ariſing from froſt. See Frost.

FROTH, a white, light ſubſtance, formed on the ſurface of fluids by vehement agitation.

Froth conſiſts wholly of little ſpherules, or globules; and, accordingly, may be defined, an aſſemblage of aqueo-aereal bubbles.

Froth, in the *Manege*, is a moiſt white matter that oozes from a horſe's mouth, otherwiſe called foam. A horſe that by champing on his bridle, throws out a great deal of froth, is judged to be a horſe of mettle and health, and to have a cold freſh mouth.

Froth-*ſpit*, or *Cuckow-ſpit*, a name given to a ſort of white froth, or ſpume, very common in the ſpring and firſt months of the ſummer, on the leaves of certain plants, particularly on thoſe of the common white field-lychnis, or catch-fly, thence called by ſome *ſpatling-poppy*. All writers on vegetables have taken notice of this froth, though few have underſtood the cauſe or origin of it, till of late. Many imagined it an exhalation from the earth; ſome have eſteemed it, as its name expreſſes, the ſaliva of the cuckow; others, the extravaſated juices of the plant, and ſome a hardened dew. But all theſe are erroneous opinions, and the account of it is, that it owes its origin to a ſmall inſect, called by ſome the flea-graſs-hopper, which applies its anus cloſe to the leaf, and diſcharges upon it a ſmall drop of a white viſcous fluid, containing ſome air in it, and, therefore, ſoon elevated into a bubble. Before this is well formed, it depoſits ſuch another drop, and ſo on, till it is every way overwhelmed with a quantity of theſe bubbles, which form this froth. See Cuckow-*ſpit*.

FROUARD, in *Geography*, a town of France, in the department of the Meurthe, ſeated on the Moſelle; four miles N. N. W. of Nancy.

FROULAY-TESSE, a town of France, in the department of the Orne; ſeven miles S. E. of Domfront.

FROUNCE, in the *Manege*, a diſeaſe in horſes, when ſmall warts or pimples ariſe in the midſt of the palate, which are very ſoft and ſore, and ſometimes breed in the lips and tongue.

This diſorder is occaſioned many ways; ſometimes by eating wet hay, whereon rats or other vermin have diſcharged urine; by drawing frozen duſt into their mouths among the graſs, &c.

As to the method of treatment, it conſiſts in letting them blood in the two largeſt veins under the tongue, and waſhing the ſores with vinegar and ſalt, or with ale and ſalt, till they bleed.

Frounce, in *Falconry*, a diſeaſe incident to hawks, ariſing from moiſt and cold humours falling down to the palate and root of the tongue; by which means they loſe their appetite, and cannot cloſe their clap. Waſhing with alum-water, lemon-juice, &c. is held good for it.

FROUQUIE, in *Geography*, a ſmall iſland in the Engliſh channel, about one mile from the W. coaſt of the iſland of Jerſey.

FROW-Fish, in *Ichthyology*, the Cyprinus *orpus*, which ſee.

FROWARD, Cape, in *Geography*, a cape on the

N. coaſt of the ſtraits of Magellan. S. lat. 54° 3'. W. long. 7 59.

FROWER, an edged tool, uſed in cleaving wood into laths.

FROWEY Timber, is that which is of the ſame degree of texture throughout, and that which works freely.

FROWSACK Channel, or the gut of Canſo, in *Geography*, a ſtrait between Nova Scotia and Cape Breton iſland, five French leagues long, and one broad.

FROYEN, an iſland in the North ſea, near the coaſt of Norway, about 35 miles in circumference. N. lat. 63° 45'. E. long. 9'.

FROZELIN, a ſmall town of France, in the department of the Creuſe, N. W. of Gueret, at the conflux of the Great and Little Creuſe.

FROZEN, or Frigid *Zone*. See Zone.

Frozen, or *Northern Ocean*, *Mare Hyperboreum*, or *Mare Scythicum*, extends from 52° or 53° N. lat. to the polar region. Between the eaſtern coaſts of Great Britain and the coaſts of Denmark and Norway, northward to the Shetland iſlands, it forms a gulf called the "German ſea." At the ſouthern extremity of Norway, an arm of that ſea almoſt environs Denmark; ſtretching eaſt and north-eaſt, it is called the "Baltic," (which ſee,) and extends from ſouth to north 300 leagues, including the gulf of Bothnia. The ſmall gulfs of Finland and Livonia lie to the eaſtward; and the former, by means of the Ladoga and Onega lakes, has a communication with the White ſea. Theſe gulfs receive the Oder, the Viſtula, the Niemen, and the Dwina, together with many rivers which deſcend from Lapland and Sweden, Finland and Livonia. An inland gulf, eaſtward from Ruſſian Lapland, is called the "White Sea," (which ſee,) into which 12 or 13 conſiderable rivers diſcharge themſelves. At the N.W. extremity of Ruſſia, the ſtrait of Waygatz in 70° N. lat., was long conſidered by geographers as a paſſage into the ſea, or gulf, that lies eaſtward along the coaſt of Grand Tartary; but the navigation of this ſtrait is now found to be impracticable, on account of the ſhoals of ice floating in thoſe parts. To paſs into the eaſtern ocean by the north of Nova Zembla is equally impoſſible, becauſe an immenſe field of ice precludes all acceſs, in this way, from Europe to the Eaſt Indies.

From North Cape in Lapland the frozen ocean ſtretches weſtward along the coaſt of Greenland; repelled by the coaſt of Labrador, it turns northward to form an immenſe gulf, large tracts of which are diſtinguiſhed by different names, as Hudſon's Bay, Davis's Strait, and Baffin's Bay.

The diſtance between North Cape, and the N. E. extremity of Tartary, is about 155 degrees or 3300 Engliſh miles. A line from that extremity acroſs the Caſpian and Red ſeas, to the Cape of Good Hope, as Mr. Buffon obſerves, is about 3,600 Pariſian leagues; and no other line of equal extent is to be found in the old continent. From North Cape to the ſouth extremity of Africa are 2,500 leagues.

The frozen ſea was, by the Goths, called Gandawyk, by the Cimbrians Mare Maruſa, and by the Latins, Mare Sarmaticum, and Mare Scythicum. The Ruſſians now call it Ledovitoë Mare; by the Swedes it is denominated Is-Hafoet, and by the Norwegians Leberſec. It borders the whole of the northern part of the Ruſſian empire from the confines of Lapland to the Tſchukotſkoy Noſs; that is, from 50 to 205 degrees of longitude, and conſequently waſhes the ſhores of the governments of Archangel, Tobolſk, and Irkutſk. Several conſiderable bays are formed by this vaſt ocean; the greateſt of which is the "White ſea," already mentioned, extending from N. to S. within the land, from 69° to 63° N. lat., and containing a multitude of petty iſlands. Of the numerous iſlands in this ocean the moſt conſiderable are Nova Zembla and Kalgueva; both uninhabited or frequented only by fiſhermen and hunters. In this great ſea, conſidered as the boundary of the Ruſſian empire weſtward, there are only three harbours whence at this time any navigation is purſued, *viz.* Kolâ, Archangel, and Meſen: but that of Archangel is the moſt famous. The ſhores in many places, more eſpecially thoſe of the White ſea, are beſet with rocks; in other parts low, with ſhoals which, in a manner, forbid acceſs, and the adjacent country is very marſhy. The water in this ſea is proportionally not very ſaline, though near Archangel it is ſo briny, that ſome quantities of common ſalt are prepared from it. The ebb and flow are moderate, and in the parts lying moſt to the north ſcarcely perceptible. The fiſhery is very conſiderable, particularly of ſtock-fiſh, herrings, whales, morſes, porpoiſes, ſea-dogs, &c. See Ocean.

Frozen *Water*. See Water.

FROZES, in *Geography*, a town of France, in the department of the Vienne; 5 miles W. of Poictiers.

FRUCHILAN, a ſmall iſland, near the Weſt coaſt of Scotland. N. lat. 58° 3'. W. long. 5° 10'.

FRUCTIFEROUS properly denotes any thing that produces fruit; but in a more large and figurative ſenſe, is uſed by lord Bacon, and others, for ſuch experiments in natural philoſophy as prove advantageous to the experimenter in point of gain or profit.

FRUCTIFICATION, in *Botany*, is uſed not only to expreſs the ſtate of a plant bearing flowers or fruit, but alſo for all the parts collectively deſtined to the production of ſeed. Theſe organs are therefore, though temporary, and often very tranſitory, of the moſt eſſential importance. By them "each ſpecies is perpetually renewed without limits, ſo far at leaſt as the obſervation of mankind has reached; while all other modes of propagation are but the extenſion of an individual, and ſooner or later terminate in its total extinction." See Linnæus on the Sexes of Plants, p. 45, note, and Smith's Introduction to Botany, 240. "The fructification," ſays Linnæus in *Philoſophia Botanica*, 52, "is a temporary part of vegetables, deſtined for the reproduction of the ſpecies, terminating the old individual and beginning the new." He juſtly conſiders the herbage, or external form of all plants, as merely a ſort of maſk or clothing, by no means indicative of their true nature or character, which are developed in the flower and fruit. Pliny had already obſerved that "bloſſoms are the joy of trees, in bearing which they aſſume a new aſpect, vyeing with each other in the luxuriance and variety of their colours." This idea is juſtly extended by Linnæus to all plants in general, and hence he deduces the importance of the parts of fructification for the purpoſes of ſcientific arrangement, a principle firſt ſuggeſted by the celebrated Conrad Geſner towards the middle of the 16th century, and which all ſyſtematic botaniſts have ever ſince kept in view. Without it the ſcience of botany would long ago have relapſed into utter barbariſm.

Linnæus diſtinguiſhes ſeven parts of fructification, ſome of which are eſſential to the very nature of a flower or fruit, others not ſo indiſpenſably neceſſary, and therefore not univerſal. Beginning at the external part of a flower, and proceeding inwards, theſe ſeven parts preſent themſelves in the following order. *Calyx*, *Corolla*, *Stamen*, or *Stamina*, *Piſtillum* or *Piſtilla*, *Pericarpium*, *Semen*, and *Receptaculum*.

1. *Calyx*, the Calyx or flower-cup, generally reſembles the leaves in texture and colour, and conſtitutes the external covering of the bloſſom. It is not always preſent, not being eſſential to a flower, whoſe neceſſary functions are independent of it. See CALYX.

2. *Corolla*, the Corolla, compoſed of one or more petals, always internal with reſpect to the calyx, and uſually more delicate in texture, and more beautifully or variouſly coloured than that part, as well as differently ſcented. This organ, however, is not more univerſal or eſſential than the foregoing. See COROLLA.

3. *Stamen* or *Stamina*, the Stamen or Stamens, which are the male organs, and therefore eſſential to every plant. Theſe are commonly of a ſlender or thread-like form, ranged internally with reſpect to the corolla, and often inſerted upon it, each bearing ſome kind of cellular body called the anther, which is the only important part, as producing the pollen or impregnating matter. See FECUNDATION *of Plants*.

4. *Piſtillum* or *Piſtilla*, the Piſtil or Piſtils, ſituated in the centre of the flower, which are the female organs, and therefore no leſs eſſential than the ſtamens, though not always ſtationed in the ſame individual flower with them. They conſiſt of the germen, or rudiments of the fruit, the ſtyle or ſtyles, and the ſtigma or ſtigmas; the firſt and the laſt only being neceſſary, as the ſtyle, ſerving merely to elevate the ſtigma more or leſs, is frequently diſpenſed with.

5. *Pericarpium*, the Seed-veſſel, of a pulpy, woody or leathery texture, when preſent encloſes and protects the ſeeds, but is wanting in many tribes of plants.

6. *Semen*, the Seed, to the formation and perfection of which all the other parts are ſubſervient.

7. *Receptaculum*, the Receptacle, baſis, or point of connection. This muſt be preſent in ſome form or other, and in compound flowers eſpecially is very remarkable.

The nature and phyſiology of theſe parts will be found under ſeveral heads in their proper places, where alſo the varieties of ſtructure in each will be explained.

Linnæus rightly calculates that the various combinations of which theſe ſeven parts are capable, muſt be ſufficient to afford generic characters for all the genera of plants which have been, or can be, diſcovered; eſpecially if we take into conſideration the peculiarities of ſtructure by which one or other of them is, in many caſes, diſtinguiſhed, and which afford the moſt deciſive and eſſential marks. The fructification therefore is our only reſource for the diſtinctive characters of genera, as well as of claſſes and orders, whether natural or artificial. It alſo frequently affords diſcriminating characters of ſpecies in a natural genus, though for theſe laſt the infloreſcence and the herbage are, for the moſt part, more conveniently reſorted to. Botaniſts of the old French ſchool more eſpecially, and others who have not ſufficiently cultivated the principles of true Linnæan ſcience, are frequently tempted to have recourſe to the infloreſcence in their generic characters, and even Linnæus was miſled by his friend Artedi to commit the ſame fault in the arrangement of the natural order of *umbellatæ*. This has not yet been well corrected, though ſome of his adverſaries have pointed it out. We are perſuaded that the proper parts of fructification are in themſelves all-ſufficient, though it may, in many inſtances, require great acuteneſs to detect what is moſt certain and natural for the deſired purpoſe, and to avoid prolixity in our definitions, while we indicate all that is eſſential.

The fructification of ſome natural orders of plants was ſo obſcure at the time when Linnæus wrote, that he was obliged to found his claſs *Cryptogamia* in order to give them any place in his ſyſtem. This is ſtill the caſe with ferns more eſpecially, (ſee FILICES,) as well as with the aquatic *Algæ*. The fructification of moſſes and lichens is now better underſtood, as will be explained in the proper place of each order.

FRUCTISTÆ. See BOTANY.

FRUGA, in *Geography*, a town of Africa; 20 miles S.S.E. of Morocco.

FRUGES, a town of France, in the department of the ſtraits of Calais, and chief place of a canton in the diſtrict of Montreuil; 12 miles S.W. of Arras. The place contains 2,700, and the canton 12,843 inhabitants, on a territory of 185 kiliometres, in 25 communes.

FRUGIVOROUS BIRDS, are ſuch as feed on fruits; either wholly or in part.

The frugivorous, according to Mr. Willughby, are a ſpecies of terreſtrial birds, ſome of which have crooked bills and claws, yet are of gentler nature, and not rapacious. Such are the parrot kind; which, though ſometimes carnivorous, yet feed likewiſe on fruit.

FRUGONI, CARLO-INNOCENZO, in *Biography*, was born of a noble family at Genoa in 1692. At the age of ſixteen he was perſuaded, but much againſt his will, to enter into a monaſtic life. He taught claſſical literature for many years in ſeveral of the cities of Italy, and at the age of thirty-five, through the interference of cardinal Bentivoglio, he was liberated from his vows, which never ſat eaſy on him, by pope Clement XII. He now obtained the patronage of the houſe of Farneſe, who gave him an honourable aſylum in Parma. When the duke eſtabliſhed an academy of Fine Arts, Frugoni was employed to draw up its ſtatutes, and was made the perpetual ſecretary. He was alſo appointed court-poet, and inſpector of theatrical exhibitions, and penſions and honours were liberally beſtowed on him. He died at Parma in the winter of 1768. He is diſtinguiſhed in Italian hiſtory as a conſiderable poet, and he maintained his reputation for vivacity and the fire of genius to a very advanced age. He excelled in various ſtyles and modes of compoſition; his printed works conſiſt of ſonnets, odes, canzoni, elegies, ſatires, eclogues and epiſtles. He had, in almoſt all he did, a ſtyle and manner peculiar to himſelf, but his lyric poetry is the moſt highly eſteemed, and in this he was ſcarcely ever ſurpaſſed by any of his countrymen. His works were collected and publiſhed in nine volumes 8vo. in the year 1779. In private life he was open and undiſguiſed, cheerful and pleaſant in converſation, but ſometimes ſarcaſtical, and more diſpoſed to talk of himſelf than to praiſe others. In ſome of his features he is ſaid to have reſembled the immortal Taſſo.

FRUHITAN, in *Geography*, an iſland near the W. coaſt of Ireland; 3 miles W. of Maſa point.

FRUIT, in its general ſenſe, includes whatever the earth produces for the nouriſhment and ſupport of animals; as herbs, grain, pulſe, hay, corn, flax, and every thing expreſſed by the Latins under the name *fruges*.

In the *civil law*, they diſtinguiſh three kinds of fruits, *viz.*: *natural*, which the earth produces ſpontaneouſly, and without any culture; as thoſe of trees; *fruits of induſtry*, which, though natural, require ſome culture to perfect them; and *civil*, which are only fruits in the eye of law; as rents, ſalaries, wages, &c.

In the *canon law*, fruits include every thing whereof the revenue of a benefice conſiſts; as glebe-land, tythes, rents, offerings, mills, &c.

FRUIT, *Fructus*, in *Botany* and *Vegetable Phyſiology*, that part

part of the fructification of plants which follows the flower, and comprehends the ſeed. All the parts of the flower are ſubſervient to the formation, impregnation, and perfection of the fruit, which is deſtined to be the ſource of a new progeny, and moſtly formed ſo as, by various means, to promote its diſperſion. All fruits are ſo conſtructed as, in the firſt place, to protect the young embryo, to nouriſh its growth, and to convey to it, by appropriate veſſels, the influence of the pollen by which it is impregnated. When the ſeed is arrived at maturity, the very ſame parts undertake a new and even contrary office, either expoſing it and letting it go, or ſerving by their own ſtructure and altered nature to convey it far away from its place of birth. The ſtricteſt connections are all diſſolved, and even mechanical force employed to accompliſh the great ends of its formation.

The fruit conſiſts of the *Pericarpium* or Seed-veſſel, and the ſeed which it contains. Some botaniſts contend that there is no ſuch thing as a ſeed truly naked, or deſtitute of a *pericarpium*, which is the opinion of M. Richard in his *Analyſe du fruit*, publiſhed at Paris in 1808, by M. Duval. This is ſo far true in a phyſiological ſenſe, that every ſeed muſt have an external coat or covering; but this coat is not more decided nor complex in what are commonly termed naked ſeeds, as thoſe of graſſes and the order *Gymnoſpermia* of Linnæus's 14th claſs, than in ſeeds encloſed in a true *pericarpium*. For botanical diſtinctions the difference between naked and covered ſeeds is uſually clear and eaſy, though in ſome inſtances the Linnæan generic definitions may be incorrect in this point, as taking a dry berry or drupa for a naked ſeed. Analogy, or a regard to natural affinities, will commonly prove ſufficient to guard us againſt this error. If any ſeeds may be ſaid to be truly naked, they are thoſe of the natural order of graſſes in general. To theſe M. Richard ſeems to allude, p. 25. "Among ſeeds preſumed to be naked," ſays he, "ſome have a pericarp very diſtinct from the proper integument of the ſeed; in others theſe two parts adhere ſo firmly together, that they appear to conſtitute one ſimple covering. The firſt may very eaſily be arranged in the ſeries of fruits, but the miſtake reſpecting the latter will be ſo much the more difficult to remove, as it is protected by an obſcurity of connection in the parts, almoſt impenetrable to a mere botanical examination. If however we have recourſe to phyſiological anatomy, and eſpecially to natural affinities, this error may be attacked with advantage, being condemned by reaſon, though excuſed by the ſenſes." He then lays down as a rule that "every thing in a ripe fruit which is external to the proper integument of a ſeed belongs to the pericarp." This no one can controvert, the only queſtion being what is ſuch integument. In graſſes nothing can be more ſimple than this part, and we cannot but reſt content with that evidence of the ſenſes which tells us a grain of wheat has no real *pericarpium*. We are nevertheleſs aware of the importance of a maxim, too much neglected in the Linnæan ſchool, that in many caſes the true nature and ſtructure of a fruit can be known only by examining it in two or more progreſſive ſtates of growth. By this means we attain a knowledge of the real number of cells, in ſome *Jaſmineæ* for inſtance, which are beſt determined in the germen, ſome of them, perhaps all but one, being obliterated in the fruit. This happens in ſome ſpecies of *Chionanthus*, which ripen but one of their four ſeeds, while others ripen two, or perhaps the whole four. Hence this genus has been improperly ſubdivided by thoſe who have examined the ripe fruit only. In general all fruits that finally become pulpy are beſt underſtood by examination when half grown, while thoſe of a capſular nature ſhew their true ſtructure as they advance towards maturity.

It is frequently difficult to diſtinguiſh between a ſimple fruit and a compound, or rather aggregate one. M. Richard juſtly obſerves, that "every ſimple fruit muſt be the produce of one ſimple flower," and that "a fruit of one cell from its earlieſt origin, independent of abortion, muſt neceſſarily be ſimple." We can ſcarcely, however, aſſent to his next poſition, "that every fruit originating from a germen with one ſtyle ought to be conſidered as ſimple." This aims at the order of *Contortæ*, in which ſurely it is offering too great violence to the ſenſes, and even to reaſon, to ſay the two pouches often ſeparate from the very beginning and totally unconnected when ripe, are one ſimple fruit, though the ſtyles are incorporated into one. "Every fruit whoſe cells are completely, and up to the ſtyle, diſtinguiſhed by true partitions, is ſimple." Of this the *Ciſtus* may ſerve for an example. "Every flower with ſeveral piſtils diſtinct throughout, muſt be allowed to have a natural plurality of fruits, though all but one piſtil may prove abortive." Of this *Caltha* and its allies are examples; and even *Delphinium*, though ſome of its ſpecies cannot, even in their earlieſt ſtate, be found to have more than one piſtil or germen. "Every fruit which, forming one ſimple maſs, preſents on its ſurface ſeveral ſcattered and diſtinct ſcars, each of which originally bore a ſtigma, is an aſſemblage of ſuch a number of fruits conſolidated into one." This is the nature of the *Anona*, and others.

As all true botaniſts have conſidered the fructification of plants as affording the only certain characters for their ſcientific diſtribution, ſo the moſt correct of theſe are generally impreſſed with a conviction of the ſuperior importance of the fruit in compariſon with the flower. The ſyſtems of Cæſalpinus, Ray, and their numerous followers, are founded on the fruit, and are infinitely preferable to thoſe of Rivinus and Tournefort, eſtabliſhed on the flower. Amongſt more modern writers Gærtner is pre-eminent for his attention to this part, and for his elaborate illuſtrations of it in about a thouſand genera. Still, as every philoſopher has a bias in favour of the leading object of his purſuit, the author laſt mentioned is juſtly thought to have ſometimes laid too much ſtreſs upon the fruit in eſtabliſhing new genera, without an enlarged and philoſophical contemplation of the whole parts of fructification, thus running counter to the excellent Linnæan law, that the "genus ought to give the character, not character the genus." We are, on the other hand, ready to admit that Linnæus, for want of an acquaintance with, or a ſufficient attention to, the fruit of ſeveral plants, has not unfrequently united what ought to be eſteemed ſeparate genera. See GENUS, PERICARPIUM, CAPSULE, FOLLICLE, DRUPA, &c.

As to the uſe of fruit, beſides the pleaſure and advantage they afford men, &c. they are of ſervice in guarding, preſerving, and feeding the ſeed incloſed; in filtrating the coarſer, more earthy, and ſtony parts of the nutritious juice of the plant, and retaining them to themſelves; and ſending none to the ſeed but the pureſt, moſt elaborated, and ſpirituous parts, for the ſupport and growth of the tender, delicate embryo, or plantule, contained therein.

So that the fruit does the ſame office to the ſeed, that the leaves of the flower do to the fruit.

The uſe of fruits with us might, under proper regulations, be rendered much more extenſive than it is. Many fruits which do hurt when eaten raw, would make wines equal in flavour to many of thoſe now obtained at great prices from abroad; and lands which will not bear corn yet would bear

trees

trees and ſhrubs producing ſuch fruits; and the conſequence of this method of culture would be, that much ground, at preſent lying waſte, would be occupied, and great employment found for the numerous poor of ſome of our counties, where the quantities of waſte land are proportionably ſo great, that there is not employment for the people of one half of the county. Cherries properly managed make an excellent wine, and that in very large quantities; and plums alſo make a very agreeable kind, but that it has an auſtereneſs, which muſt be taken off by mixing a little ſugar with it when in the glaſs, not before it is drawn off

A coarſe plum, ſomewhat larger than a damſon, is the beſt kind for this wine. There is a ſort of plum that grows wild in ſome of our hedges. It will ſucceed on any ground, the pooreſt that can be imagined, and it produces a great abundance of fruit. The wine that is made from it is of a very conſiderable ſtrength, and affords a pleaſant brandy by diſtillation in conſiderable quantities. Our common garden currants afford a very agreeable wine; and our gooſeberries are not ſecond to any thing. All theſe produce fruit in great abundance; and the planting and taking care of them is very cheap, and the operation very eaſy. The common way of making theſe wines yields very good ones; but when the art of the experienced Vigneron is employed in it, the liquors will prove much better. Phil. Tranſ. N° 124.

Fruits are diſtinguiſhed by gardeners into ſtone-fruit and kernel-fruit; ſummer-fruit and winter-fruit; wall-fruit and dwarf-fruit, &c.

M. Quintinie obſerves, that cold, heavy moiſt lands, produce the faireſt and largeſt fruit; but the hotter, drier, and lighter, the more delicious and rich-taſted.

FRUIT *Stalk*. See PEDUNCULUS.

FRUIT, in *Gardening*, the produce of various ſorts of trees uſed as food, either in a raw or prepared ſtate by fire.

All ſorts of fruit ſhould be gathered from the trees or plants when perfectly dry, and never when in a dewy or wet condition. In many of the finer and more delicate fruits, it is of advantage not to permit them to remain on the trees till they are over-ripened. In gathering them, the bloom ſhould always be preſerved upon them as much as poſſible. In the almond, peach, and plum, and finer cherry kinds, it is uſual to depoſit them, as ſoon as gathered, in ſhallow ſieves or baſkets, ſpread over with leaves, or ſome other ſimilar material.

In the gathering of apples and pears, (as thoſe which are ſhaken or beaten from the trees never keep well,) Mr. Forſyth adviſes that they ſhould be all hand-picked, by means of a ſtage or ſteps contrived for the purpoſe, and other apparatus neceſſary for receiving and conveying them away; ſome dried ſhort cut graſs being employed to prevent their being bruiſed on being depoſited in them.

It is likewiſe further obſerved, that great attention ſhould be paid to their ripening, never gathering them at any particular period or ſeaſon, as is often the caſe, on account of their becoming ripe at different times according to circumſtances, but to be regulated by the ſound fruit, where the trees are healthy, coming off into the hand without any force, on being taken hold of; it ſhould be picked off the trees and laid in the baſkets and other places in a careful manner, ſo as to prevent burſting. When it is ſuffered to remain till it begins to fall itſelf, ſome well-dried ſhort graſs mowings, peaſe-haum, barley-ſtraw, or other ſimilar dry material, is recommended to be ſpread over the ſurface of the ground, to prevent the fruit being bruiſed by falling. But the fruit collected in this way ſhould conſtantly be laid up ſeparately, and made uſe of before that which was gathered by the hand; all ſuch as are bruiſed being laid aſide for immediate uſe in the family.

After all the fruit has been gathered, the hay or ſtraw ſhould be raked up and removed from the place.

When the fruit is wholly collected, it muſt be depoſited in the ſtore or fruit-room, ſome of the dried ſhort graſs being previouſly ſpread over the middle part of the floor. It ſhould be carefully laid in heaps from the baſkets upon the dried graſs, each ſort ſeparate; the heaps being from two to three feet in height, according to the quantity of fruit. When the heaps have been formed, they ſhould be covered with the ſame material as was laid on the floor, to the thickneſs of two inches or more, in order that they may ſweat. When they have remained in this ſtate a fortnight, they ſhould be opened and turned over, wiping each with a woollen cloth often dried, carefully removing thoſe that were at the tops to the middle. After having continued eight or ten days more covered as before, the watery material will be ſufficiently expended, when the fruit muſt be again looked over and wiped as in the former caſe, rejecting all ſuch as are in the leaſt degree injured by being bruiſed or otherwiſe.

While the proceſs of ſweating is going on, the windows of the room ſhould be kept open, when the weather is not moiſt, to promote the exhalation of moiſture. When the ſweating is very conſiderable, it will be neceſſary to turn and wipe the fruit during the time the proceſs is going on.

Wheat ſtraw has been commonly made uſe of in laying up this ſort of fruit; but Mr. Forſyth has found, that when any of the fruit begins to decay, if it be not quickly removed, the ſtraw imbibes the moiſture iſſuing from it, and communicates an unpleaſant taſte to ſuch as is ſound and unaffected.

When fruit is ſtored upon ſhelves in the rooms, it is recommended to have the bottoms covered with thin coarſe canvas, at about eight-pence or ten-pence the yard, and to place them upon it in ſingle layers, after being wiped quite dry, care being taken not to lay them upon each other. They ſhould then be covered with a piece of the ſame canvas, old news, or whited brown paper, to exclude the action of the air, guard againſt froſt, and preſerve the ſmoothneſs on the ſkin of the fruit. It ſhould be turned two or three times in the courſe of the winter, to guard againſt rotting on the under ſide, all the damaged fruit being carefully removed each time.

In ſtoring it in this manner, the earlieſt ſorts ſhould be placed on the lower ſhelves or drawers according as they come in, in this order; the non-ſuch, golden-rennet, and jenneting apples, and the burgamot and burro pears; as the jargonelle is found to keep beſt on the tree, rotting almoſt immediately on being gathered. In this way a proper ſucceſſion of fruit may be provided.

As it requires much time in ſtoring in this way where there is much fruit, it may be done in wet weather, and the evenings, when the men can be better ſpared than in the day-time.

Where there are not proper fruit-rooms, this ſort of fruit may be kept in ſtore-houſes in baſkets or hampers, placing ſoft paper in the bottoms and round the edges to prevent bruiſing them, laying a layer of fruit and a layer of paper alternately, covering the top with paper three or four times folded, to guard againſt the air and froſt, which are liable to injure them.

All the different ſorts of fruit ſhould be packed ſeparately, and have labels faſtened to them, ſo as to know their names, and the times of their being in a proper ſtate for uſe in the family.

But

But the beſt way of keeping fruit is, however, Mr. Forſyth thinks, by packing it up in glazed earthen pans or jars. In doing which, the fruit ſhould be firſt ſeparately wrapped in ſoft paper, then a little well-dried bran applied over the bottoms of the jars, above which a layer of fruit ſhould be placed, continuing them alternately, till the jars are quite full, when they ſhould be ſhaken, and a little more bran added, covering the whole over with bladders to exclude the air, putting on the covers, which ſhould fit in a cloſe manner. The rooms in which theſe are placed ſhould be capable of admitting a fire in moiſt weather, in order to dry up the dampneſs.

In the buſineſs of packing fruit for carrying, Mr. Forſyth thinks ſtrong deal boxes of different ſizes the moſt convenient and uſeful. Thoſe which he employs are two feet long, having the breadth and depth of fourteen inches; and one foot nine inches long, with one foot in breadth and depth. They are conſtructed of inch-deal, well ſecured by cramps at the corners, having a ſmall iron handle at each end to ſecure them by. In theſe, melons, currants, cherries, pears, peaches, nectarines, plums, grapes, and other ſimilar ſorts of fruit may be carried; the heavieſt fruit of each ſort being put at the bottom, the firſt ſort wrapped up in ſoft paper, and all the others, except the currants and cherries, firſt in vine-leaves, and then ſoft paper. The other two may be conveyed in flat tin boxes, about fourteen inches in length, ten in breadth, and four in depth, with perfect ſafety.

In packing them, for the melons, a layer of fine moſs and ſhort, ſoft, dry graſs, well blended together, is placed at the bottom of the deal box, and then the melons packed in with it in a light manner, in every direction, chooſing them as much of the ſame ſize as poſſible; when the melons are put in, a thin layer of moſs and graſs is placed over them, upon which the tin box, having the currants and cherries packed in it by intervening layers of fine dry moſs, ſo as to be quite full, is packed firmly in with graſs and moſs all round, to prevent its moving; over which another thin layer of moſs is ſpread, and the pears, packed in cloſely in the ſame manner as the melons, proceeding in the ſame way with the other fruits, ſo as to cloſe with the grapes, filling up with moſs, ſo as that the lid of the box may ſhut down quite tight, and prevent rubbing. Each box ſhould be provided alſo with a lock and two keys, to ſerve the whole, one for the packer, and another for the emptier. When the boxes are locked down they ſhould be well corded and kept ſteady.

FRUIT *Garden*, that ſort of garden which is principally planted with trees, for the purpoſe of affording fruit of different kinds. The ſituation of this ſort of garden ſhould be warm, ſheltered, and open to the ſouth, or ſouth-weſt, in order that it may enjoy the benefit of the ſun, and of courſe ripen the fruit in the beſt and moſt perfect manner. See GARDEN and ORCHARD.

FRUIT *Room*, an erection conſtructed for the purpoſe of ſtoring up different ſorts of fruit. Theſe rooms are formed of different dimenſions according to circumſtances, being lined with thin boards, and fitted up with ſhelves, bins, boxes, drawers and other conveniences for the reception of fruit; all of which, as well as the floors, ſhould be of white deal, as Mr. Forſyth remarks, that when red deal is made uſe of for theſe purpoſes, it is liable to give a diſagreeable reſinous taſte to the fruit, and ſpoils its flavour on this account; under other circumſtances he adviſes covering the ſhelves with canvas, &c. as mentioned in the preceding article FRUIT.

FRUIT *Tree*, is that ſort of tree which produces eatable fruit, either for the table, or culinary uſes, or both.

There are many fruit-trees, fruit-bearing ſhrubs, and ſhrubby plants that ripen their fruit perfectly in this climate, with their ſeveral ſpecies and numerous varieties; the principal ſorts of which are thoſe of the almond kind, as the almond, peach, and nectarine trees; the plum ſort, containing different kinds of plums, apricot, and cherry trees; the pear kind, comprehending various ſorts of pears, apples, and quince trees; the vine, containing many ſorts of grape trees; the fig, comprehending many ſorts of fig trees, the ſeveral ſorts of medlar trees, the different kinds of mulberry trees, the cheſnut, and walnut trees; the common nut kind, containing many ſorts of filberts, and other nut trees; the currant, gooſeberry, and raſpberry trees, with many others; the nature and management of each of which will be fully explained under their reſpective genera and heads.

All ſorts of fruit trees require conſiderable attention in ingrafting, planting, tranſplanting, training, pruning, thinning, and other ſorts of management. See GRAFTING, TRAINING, PRUNING, &c. See alſo ORCHARD-GARDEN, ORCHARD, and NURSERY.

FRUIT and TREES, *ſtealing of*. By ſtat. 4 Geo. II. c. 32. to ſteal, damage, or deſtroy underwood or hedges, or the like, to rob orchards, or gardens of fruit growing therein, to ſteal, or otherwiſe deſtroy any turnips, potatoes, cabbages, parſnips, peaſe, or carrots, or the root of madder, when growing, are puniſhable criminally, (by ſtats. 43 Eliz. c. 7. 15 Car. II. c. 2. 31 Geo. II. c. 35. 6 Geo. III. c. 48. 9 Geo. III. c. 41. 13 Geo. III. c. 32.) by whipping, ſmall fines, impriſonment, and ſatisfaction to the party wronged, according to the nature of the offence. Moreover, the ſtealing by night of any trees, or any roots, ſhrubs or plants to the value of 5*l.* is, by ſtatute 6 Geo. III. c. 36, made felony in the principals, aiders, and abettors, and in the purchaſers thereof, knowing the ſame to be ſtolen. And by ſtats. 6 Geo. III. c. 48. and 13 Geo. III. c. 33. the ſtealing of any timber-trees, therein ſpecified (*viz.* oak, beech, cheſnut, walnut, aſh, elm, cedar, fir, aſp, lime, ſycamore, birch, poplar, elder, larch, maple, and hornbeam), and of any root, ſhrub, or plant, by day or night, is liable to pecuniary penalties, for the two firſt offences, and for the third, is conſtituted a felony, liable to tranſportation for ſeven years. See LARCENY.

FRUITS, *Summer*, *Fructus horæi*, in the *Materia Medica*, comprehend ſtrawberries, cherries, currants, mulberries, raſpberries, and ſuch like. They poſſeſs a ſweet, ſubacid taſte, and are exhibited as dietetic auxiliaries, as refrigerants, antiſeptics, attenuants, and aperients. They were formerly adminiſtered medicinally in the cure of putrid affections, and to promote the alvine and urinary excretions. As an article of diet, they afford little nouriſhment, and are apt to produce flatulencies. To perſons of a bilious conſtitution and rigid fibres, and whoſe habit is naturally, or from extrinſic cauſes, diſpoſed to an inflammatory or putreſcent ſtate, the moderate and even plentiful uſe of them is ſalubrious; but perſons of a cold, inactive diſpoſition, with lax veſſels, languid circulation, and weak digeſtion, ſhould uſe them ſparingly. The juices extracted from theſe fruits by expreſſion, contain their active qualities freed from their groſſer, indigeſtible matter. On ſtanding, the juice ferments, and changes to a vinous or acetous taſte. By the proper addition of ſugar, and by boiling, their fermentative power is ſuppreſſed, and their medicinal qualities preſerved. The juices of theſe fruits, purified from their feculencies by ſettling and ſtraining, may be made into ſyrups, with a due proportion of ſugar in the uſual way.

FRUIT, in *Natural Hiſtory*, denotes the laſt production of a tree,

a tree, or plant, for the propagation or multiplication of its kind; in which ſenſe fruit includes all kinds of ſeeds, with their furniture, &c.

FRUITS, *petrified*, (*Carpolithi*) are a numerous family of the organic remains or relics of a former ſtate of the globe; according to early writers, who have deſcribed a great number of different fruits, found in a petrified ſtate in the earth; many of theſe are enumerated by Mr. Parkinſon, (Organic Remains, letter 48, vol. i.) and ſhewn to be mere miſtakes, as all of them undoubtedly are. The enumeration of theſe kinds of bodies, which we propoſe to give under their moſt common or vernacular names, will point out theſe miſtakes, and refer the foſſils to their proper claſs, when it can be done; with particular reference to the authors who have deſcribed them, which will, we truſt, contribute much to diſſipate the cloud of error which ſtill, and for a long time, without ſuch an expoſition, muſt continue to hang on the minds of thoſe unacquainted with the laborious details of natural hiſtory, reſpecting the real nature of the reliquia found entombed in the earth, which knowledge now appears to have an important uſe and application, in identifying the ſtrata, and trying the validity of the different geological ſyſtems which have been framed to account for the many aſtoniſhing appearances which the earth preſents.

FRUITS, *Colours from*. The red juices of fruits, as of currants, mulberries, elder-berries, morello, and black cherries, when inſpiſſated and dried, may be again diſſolved in water, to which they give nearly the ſame red colour as they do when freſh. Rectified ſpirit extracts the tinging particles, and acquires a brighter colour than the watery ſolution; becauſe much of the mucilage is left undiſſolved by the former. The red ſolutions, and the juices, are ſometimes made dull, and ſometimes more florid, by acids, and are generally rendered purpliſh by alkalies. The colours of theſe juices are generally periſhable. They reſiſt the power of fermentation, but quickly decay, when the jucies are ſpread thinly on any ſubſtance, and dried in open air. The bright lively reds are ſooneſt changed; the dark, dull, red ſtain of the black cherry is conſiderably durable. The bright red fruit of the opuntia, or prickly pear, is an exception to the above rule; as it gives, according to Labat, a beautiful red dye. The ripe berries of buckthorn ſtain paper of a green colour; from theſe is prepared the ſubſtance called ſap-green; which is a pigment ſufficiently durable, ſoluble in water, but not miſcible with oil. The berries, when green, yield a yellow, and, when over-ripe, a purple pigment. Woollen cloth, prepared with alum and tartar, receives, on being boiled with the berries, a periſhable yellow dye. Neumann's Chem. with Dr. Lewis's Notes, p. 433. See AVIGNON *Berry*, ANNOTTO, or ROUCOU, and TURNESOL.

FRUITS, *Preſervation of*. See FRUIT, in *Gardening*, *Preſervation of* FLOWERS, and *Preſervation of* VEGETABLES.

For the early ripening of fruits, ſee FORCING and RIPENING.

FRUIT, *Bread*. See BREAD.

FRUITS, with regard to commerce, are diſtinguiſhed into *recent*, or *freſh*, and *dry*.

FRUITS, *recent*, are thoſe ſold juſt as they are gathered from the tree, without any further preparation; as are moſt of the productions of our gardens and orchards, ſold by the fruiterers.

FRUITS, *dry*, are thoſe dried in the ſun, or by the fire, with other ingredients ſometimes added to them to make them keep; imported chiefly from beyond ſea, and ſold by the grocers.

Such are raiſins, currants, figs, capers, olives, cloves, nutmegs, pepper, and other ſpices; which ſee under their reſpective articles.

Under the denomination of dry fruits are alſo frequently included apples, pears, almonds, filberts, &c.

FRUITS, *polypyreneous*. See POLYPYRENEOUS.

FRUITS *current for Coins*. See COIN.

FRUITS, *Firſt*. See FIRST *fruits*, ANNATES, and PRIMITIÆ.

FRUIT-*flies*, a name given by gardeners, and others, to a ſort of ſmall black flies, found in vaſt numbers among fruit-trees, in the ſpring ſeaſon, and ſuppoſed to do great injury to them.

Theſe are a ſpecies of ſmall black fly. Mr. Leewenhoek preſerved ſome of them for his microſcopical obſervations. He found that they did not live longer than a day or two, but that the females in this time uſually laid a great number of longiſh eggs. The gardeners, who ſuppoſe that theſe flies wound the leaves of the trees, are miſtaken: it is true that they feed on their juices, but they have no weapons with which to extract this themſelves; they feed on ſuch as is naturally extravaſated, and when there is not enough of this for their purpoſe, they haunt thoſe places where the pucerons reſort, and feed on the juices which theſe little creatures extravaſate by means of the holes they bore in the leaves with their trunks. Theſe pucerons are a ſmall ſort of inſect very common in our fruit-trees, and other plants and trees; they are of a greeniſh colour, and are commonly called tree-lice. Phil. Tranſ. No. 262.

FRUIT-*ſtones*. The miſchiefs ariſing from the bad cuſtom of many people ſwallowing the ſtones of plums and other fruit are very great. The Philoſophical Tranſactions give us an account of a woman who ſuffered violent pains in her bowels for thirty years, returning once in a month, or leſs. At length a ſtrong purge being given her, the occaſion of all theſe complaints was driven down from her bowels to her anus, where it gave a ſenſation of ſtoppage and diſtenſion, and produced a continual deſire of going to ſtool, but without voiding any thing. On the aſſiſtance of a careful hand in this caſe there was taken out with a forceps an oblong ball of an oval figure, of about ten drams weight, and meaſuring five inches in circumference: this had cauſed all the violent fits of pain ſhe had been ſo many years afflicted with, and after the taking it out ſhe became perfectly well. The ball extracted looked like a ſtone, and felt very hard, but it ſwam in water; on cutting it through with a knife there was found in the centre of it a plum-ſtone, round which ſeveral coats of this tough and hard matter, reſembling a ſtone, had gathered. Another inſtance given in the ſame papers is of a man, who dying of an incurable colic, which had tormented him many years, and baffled the effects of medicines, was opened after death; and in his bowels was found the cauſe of his diſtemper, which was a ball of the like nature with that juſt mentioned, but ſomething larger, being ſix inches in circumference when meaſured, and weighing an ounce and a half; in the centre of this, as of the other, there was found the ſtone of a common plum, and the cuts were of the ſame matter with thoſe of the former. Theſe, and ſeveral other inſtances mentioned in the ſame place, ſufficiently ſhew the folly of that common opinion, that the ſtones of fruits are wholeſome.

For

For though by nature the guts are ſo defended by their proper mucus, that people very ſeldom ſuffer by things of this kind, yet if we conſider the various circumvolutions of the guts, their valves and cells, and at the ſame time conſider the hair of the ſkins of animals we feed on, the wool or down on herbs and fruits, and the fibres, veſſels, and nerves of plants, which are not altered by the ſtomach, it will appear a wonder that inſtances of this ſort of miſchief are not much more frequent. Cherry ſtones, ſwallowed in great quantities, have occaſioned the death of many people, and there have been inſtances even of the ſeeds of ſtrawberries, and kernels of nuts, collected into a lump in the guts, and cauſing violent diſorders, which could never be cured till they were carried off. Phil. Tranſ. No. 282. p. 1282.

FRUITERY, a place for the laying up and keeping of fruit. See GRANARY.

The fruitery ſhould be inacceſſible to any thing of moiſture, or even froſt.

FRUITFULNESS, the quality of bearing plenty of fruit, called alſo *fertility*, or *fecundity*.

FRUMENTACEOUS PLANTS are thoſe which produce geniculated or knotted ſtalks, with reed-like leaves; and whoſe ſeed growing in ſpikes or jubæ, is uſeful to make pultege, or bread.

The word is formed from *frumentum*, a general name comprehending all ſorts of corn, or grain, for bread. Hence the Italians, who follow the Latins, uſe *grano* and *frumento* for the ſame.

Wheat, barley, rye, millet, &c. are frumentaceous plants. Some authors uſe frumentaceous in a narrower ſenſe, reſtraining it to plants which bear a conformity to wheat, either in reſpect of their fruits, leaves, ears, or the like.

But this ſeems founded on a miſtaken notion of *frumentum*, as if it denoted only *wheat*, which is rather the ſenſe of the word *triticum*.

FRUMENTARII, in *Antiquity*, a kind of ſoldiers or archers, under the Weſtern empire.

St. Cyprian relates, in one of his letters, that ſome of theſe frumentarii were ſent to take him.

The firſt time we read of frumentarii, as officers, is in the time of the emperor Adrian. Spartian, in his life of that prince, aſſures us, that he made uſe of them to inform himſelf of what paſſed.

Before this time, the name frumentarius was only given to the corn-merchants, or meaſurers of corn.

Theſe frumentarii did not make any particular corps, diſtinct from the other forces, but there was a certain number of them in each legion, as, among us, there is a certain number of grenadiers in each battalion. Accordingly, in ancient inſcriptions, we meet with frumentarii of this or that legion. It is ſuppoſed they were originally a number of young perſons, diſpoſed by Auguſtus throughout the provinces, particularly on all the grand roads to advertiſe the emperor, with all expedition, of every thing that happened.

In order to this they had a kind of intendance of all the carriages, and on this account came to be employed for the conveyance of corn, *frumentum*, to the armies; whence their appellation

Afterwards they were incorporated into the troops themſelves, where they ſtill retained their ancient name.

Their principal office was the giving intelligence, in which they agreed with thoſe called *curioſi*, with whom they were frequently joined. See CURIOSUS.

The function of theſe ſoldiers at firſt was to diſtribute to their comrades the meaſures of corn allotted to each man; and as their miniſtry gave them an opportunity of knowing all the ſoldiers of a cohort, or a legion, they were directed to examine into their characters, and give an account of ſuch as they ſhould believe to be ſeditious, and capable of raiſing diſturbance. Their commiſſion was afterwards enlarged, and they were authoriſed to obſerve, not only in the legion, but in the cities and provinces, every commotion, every ſuſpicion of revolt, and to give notice of it to the court. Thence aroſe perpetual informations, and frequent calumnies againſt innocent people, many of whom periſhed upon falſe accuſations of treaſon, always too readily liſtened to by princes. Theſe public ſpies were ſuppreſſed by Diocletian, for which popular act he was univerſally applauded. However, either he or his ſucceſſors eſtabliſhed in their room agents or officers, who ſoon became equally formidable and pernicious.

FRUMENTATION, FRUMENTATIO, among the *Romans*, a largeſs of corn beſtowed on the people. This practice, of giving corn to the people, was a very ancient cuſtom among the Romans, and frequently uſed to ſoothe the turbulent humour of the populace.

At firſt the number of thoſe to whom this largeſs was given, was indeterminate, till Auguſtus fixed it at two hundred thouſand.

FRUMENTIUS, in *Biography*, a ſaint in the Roman calendar, entitled the "Apoſtle of Ethiopia," was a native of Tyre, and flouriſhed in the fourth century. He was educated under Meropius, a chriſtian philoſopher, who embarked in a voyage to India, and was accompanied by Frumentius and another ſcholar named Ædæſius, but having the misfortune to touch on the coaſt of Ethiopia, Meropius was inhumanly murdered by the natives, and his ſcholars ſent up the country to be ſlaves to the emperor. This prince conferred upon them poſts of honour about his perſon, and in his houſhold; ſhewed them marks of his favour, and a little before his death gave them their liberty. They now propoſed to return to their native country, but at the earneſt ſolicitations of the queen, they conſented to remain ſome time longer to ſuperintend the education of the young prince. In this confidential ſituation they were enabled to perform many kind actions; and among others they obtained liberty for the Roman merchants reſiding in the ports of Ethiopia, who were chriſtians, to aſſemble together for the worſhip of God, and they ſucceeded in making many converts, among the courtiers, to chriſtianity. As ſoon as their pupil had taken on himſelf the management of the government, they, after much difficulty, were allowed to return home. Frumentius repaired to Alexandria, acquainted Athanaſius, who was biſhop of that city, with the progreſs that had been made in introducing Chriſtianity into Ethiopia, and pointed out to him what proſpects there were of farther ſucceſs. Frumentius, at the ſolicitation of Athanaſius, was ſoon after conſecrated a biſhop, and appointed on a miſſion to Ethiopia. This was in the year 331; he entered upon his labours at Axuma, the capital of the country, and was ſo ſucceſsful, that in a ſhort time the emperor, and a great body of his people, were converted to the chriſtian faith, and numerous churches were eſtabliſhed throughout the empire. Moreri.

FRUMENTUM SARACENICUM, in *Botany*, a name by which ſome authors expreſs the fagopyrum, or buck-wheat. See POLYGONUM.

FRUMENTUM *Indicum*, *Indian corn*, a name given by our American planters to *Maize*, which ſee.

FRUMENTY, popularly *Furmety*, a kind of pottage, the baſis whereof is wheat, boiled up with milk, ſugar, and ſometimes ſpice.

Pliny tells us, that in his time they mixed chalk among it.

Galen deſcribes it as a very nutritious food made of corn, or pulſe, boiled with water, wine, and oil.

The Latins called it *alica*, which Feſtus derives *ab alendo*, as being very nouriſhing. But then it muſt be obſerved, they made it of any kind of corn.

Ours being reſtrained to wheat, we have given its denomination accordingly, from *frumentum*. An emulſion, wherein wheat was an ingredient, would be a kind of frumenty.

FRUMGYLD, in our *Old Writers*, is the firſt payment made to the kindred of a perſon ſlain, towards the recompence of his murder. L. L. Edmund.

FRUMO, in *Geography*, a ſmall iſland on the weſt ſide of the gulf of Bothnia. N. lat. 65° 23'. E. long. 21° 37'.

FRUMSTOL, in our *Old Writers*, the chief ſeat or manſion-houſe, which is called by ſome the *homeſtal*. Leg. Inæ, cap. 38.

FRUNDELE, in *Agriculture*, the name of a dry meaſure, which conſiſts of two pecks, or half a buſhel. It is only uſed in particular diſtricts.

FRUR, or NOBFLEUR, or *Tavem*, in *Geography*, a ſmall iſland in the Perſian gulf. N. lat. 26° 10'. E. long. 54° 20'.

FRUSH, or FROG, in the *Manege*, is a ſort of tender horn which ariſes in the middle of the ſole, and at ſome diſtance from the toe of a horſe; it divides into two branches, running towards the heel, in form of a fork.

FRUSINUM, in *Ancient Geography*, a town of Italy, in the country of the Volſci, on the confines of that of the Hernici, at the 54th mile from Rome on the Latin way; 7 miles from Ferentinum, and 14 from Fregellanum, near the ſmall river Coſa. In the year of Rome 450 it was taken by the Romans; but in proceſs of time, they rebuilt its walls, planted in it a colony, and diſtributed the adjacent land among the victors. It is now *Fraſinone*, in the Campagna; 25 miles E. of Veletri. N. lat. 41° 40'. E. long. 13° 13'.

FRUSSURA, in our *Old Writers*, a breaking down; alſo a ploughing or breaking up. *Fruſſura domorum* is houſe-breaking; and *fruſſura terræ*, new broken land.

The word comes from the French, *froiſſure*, a bruiſe; and that from the verb *froiſſer*, to bruiſe or break.

FRUSTUM, in *Mathematics*, a piece cut off or ſeparated from a body.

FRUSTUM of a pyramid, or cone, is that part which remains when any part next the vertex, cut off by a plane parallel to the baſe, is taken away.

The fruſtum A B C D E F A (*Plate* VII. *Geometry*, *fig.* 88.) of any pyramid having a triangular baſe, is equal to a whole pyramid, of the ſame baſe and altitude, together with two other pyramids that are in proportion to it; the one, as any ſide B D of the upper baſe B C D, is to its correſpondent A E of the ſame baſe A F E, and the other, as the ſquare of the former ſide is to the ſquare of the latter.

In the planes of the three ſides, draw the diagonals B E, B F, and F D; then will the part B C D of the fruſtum, cut off by a plane extended by F B and F D, be a pyramid on the baſe B C D, having the ſame altitude with the fruſtum itſelf, both ſolids being contained between the ſame parallel planes A F E, B C D. Moreover, the remaining part F A B D E of the fruſtum, if a plane be extended by F B and F E, will be divided into the two pyramids F B D E, F A B E, having the ſame ratio, one to the other, as their baſes B E D, A B E, or as B D to A E. But the latter of theſe pyramids B A F E, taking B as its vertex, has the ſame baſe and altitude with the fruſtum given; and the pyramid F B C D is in proportion to it as the baſe B C D to the baſe A F E, that is, the baſes being ſimilar, as BD^2 to AE^2.

Hence it follows, that ſince of the three ſolids, F A B E, F B D E, F B C D, into which the fruſtum is divided, the ratio of the firſt and third is the duplicate of that of A E to B D, or of the ratio of the firſt to the ſecond, theſe three ſolids are proportional. Whence it appears, that the fruſtum of any triangular pyramid is equal to two whole pyramids of the ſame altitude on baſes, equal to the two oppoſite baſes of the fruſtum, and to a third pyramid, which is a mean proportional between the two former. And beſides, whatever is demonſtrated in relation to triangular pyramids, muſt hold equally in all pyramids and cones; becauſe every ſuch ſolid is equal to a triangular pyramid of equal baſe and altitude; and every fruſtum of the one is alſo equal to the correſponding fruſtum of the other. See PYRAMID.

From the propoſition above demonſtrated we may deduce a method of finding the content of any fruſtums of pyramids and cones. Firſt, Let the fruſtum M N be that of a pyramid; then, having found the content of a whole pyramid, of the ſame given baſe and altitude (ſee PYRAMID); ſay, as any ſide A of the lower end or baſe is to its correſpondent B of the upper, ſo is the ſaid content to a fourth proportional; and as A is (again) to B, ſo is the quantity laſt found to another proportional; which two proportionals, added to the content firſt determined, will give the true content of the fruſtum. That theſe quantities anſwer to the conditions of the propoſition will appear from the following ſtatement, P being the whole pyramid; thus, $A : B :: P : D$ and $A^2 : B^2 :: P : C$, which is equal to a fourth proportional to A, B, and D; for, in the one caſe, $C = \frac{B^2 \times P}{A^2}$, and in the other, $C = \frac{D \times B}{A}$, becauſe $D = \frac{B P}{A}$; and therefore $C = \frac{B^2 \times P}{A^2}$.

When the oppoſite baſes of the fruſtum are ſquares, the rule will be more ſimple, and put on a better form: for then the area of the baſe being A^2, the content of a whole pyramid on that baſe, of the ſame altitude with the fruſtum, will be equal to the parallelepipedon $C \times A^2$; C being $\frac{1}{3}$d of the given altitude of the fruſtum. But $A : B :: C \times A^2 : C \times A \times B$ (ſee PARALLELEPIPEDON); and $A : B :: C \times A \times B : C \times B^2$; therefore, $C \times A^2 + C \times A \times B + C \times B^2 = C \times A^2 + A \times B + B^2$, the content required. Hence we obtain the following rule for finding the content of the fruſtum of any ſquare pyramid: Add the product of the two ſides of the lower and upper ends to the ſum of their ſquares, and then multiply the aggregate by $\frac{1}{3}$d of the pyramid's height. Secondly, from the content now found, that of any conical fruſtum P Q (*fig.* 90) is readily obtained; being in proportion to the content $C \times A^2 + A \times B + B^2$ of the fruſtum of a ſquare pyramid circumſcribing it, as the baſe of the former is to the baſe of the latter; or, as the fraction ,7854 is to unity; this being the proportion of the area of the circular baſe to the ſquare on the diameter: thus, $PQ : C \times A^2 + A B + B^2 :: ,7854 : 1$; therefore $P Q = ,7854 \times C \times A^2 + A B + B^2 =$ (calling the altitude *a*) $,7854 \times \frac{1}{3} a \times A^2 + A B + B^2 = ,2618 \times a \times A^2 + A B + B^2$ or $= E \times A^2 + A B + B^2$, by taking $E = ,7854 \times C =$ the ,2618th part of the whole given altitude. Hence, for finding the content of any fruſtum of a cone, we have the following rule: Add the product of the diameters of the two ends to the ſum of their ſquares; then multiply the aggregate by the fruſtum's height, and the product, again, by the fraction ,2618.

Thirdly.

Thirdly. For finding the content of any ſegment I A K (*fig.* 91.) of a ſphere, a rule may be deduced in the following manner. It appears from the property of the ſphere (ſee SPHERE,) that the ſegment propoſed, I A K, is equal to the difference between a conical fruſtum F C D H, and a cylinder E C D G of the ſame altitude, ſtanding upon a baſe, whoſe radius C A is equal to that A O of the ſphere itſelf; the cone being $\frac{1}{3}$d of a cylinder of the ſame baſe and altitude; and the difference of the cone and cylinder being $\frac{2}{3}$ds of the latter or equal to the ſphere, and like parts being as their wholes. But the content of the fruſtum F C D H, if the two diameters C D and F H be repreſented by A and B, and the ,2618th part of the altitude D by E, will be $= E \times \overline{A^2 + A \times B + B^2}$ (that is, equal to a parallelepipedon whoſe altitude is E and baſe $= \overline{A^2 + A \times B + B^2}$.) And the content of the cylinder E C D G will be $= 3\,E \times A^2$, or $E \times 3\,A^2$; becauſe $3\,E = 3 \times ,2618\,D = ,7854 \times D$; and the content of the cylinder = the area of the baſe multiplied by its height (ſee CYLINDER); but the area of the baſe is, from the property of the circle, $= ,7854 \times A^2$, and the height $= D$: therefore $3\,E \times A^2 = ,7854 \times D \times A^2 =$ the content of the cylinder. Conſequently, the difference, or the content of the ſegment I A K, will be $= E \times 3\,A^2 - E \times \overline{A^2 + A\,B + B^2} = E \times \overline{2\,A^2 - A \times B - B^2}$. But $2\,A^2 - A \times B - B^2$ is compoſed of $A^2 - A \times B$ and $A^2 - B$; the former part of which $A^2 - A \times B$ is $= \overline{A - B} \times A = 2\,D \times A$ (becauſe A − B, or C D − F H = E F + H G = 2 A B or 2 D, becauſe the triangle E F C, being equiangular with C O A, is iſoſceles); and the latter part $A^2 - B^2 = \overline{A - B} \times \overline{A + B} = 2\,D \times \overline{2\,A - 2\,D}$; $\overline{A - B}$ being equal C D − F H = 2 D, and $\overline{A + B} = \overline{E\,G + F\,H} = E\,G + \overline{E\,G - 2\,D} = 2\,A - 2\,D$. Whence the ſum of both parts will be $= 2\,D \times \overline{3\,A - 2\,D}$; and the content of the ſegment itſelf $= E \times 2\,D \times \overline{3\,A - 2\,D} = ,2618\,D \times 2\,D \times \overline{3\,A - 2\,D} = ,5236 \times D^2 \times \overline{3\,A - 2\,D}$. Hence we have the following rule for finding the content of any ſegment of a ſphere: Multiply the ſquare of the ſegment's height by the exceſs of thrice the ſphere's diameter above the double of that height; and then multiply by the fraction ,5236. See SEGMENT.

Otherwiſe. To find the ſolidity of the fruſtum of a pyramid; add into one ſum the areas of the two ends and the mean proportional between them, and then multiply the ſaid ſum by the perpendicular height, and $\frac{1}{3}$d of the product will be the ſolidity. *E. G.* If A be the area of the greater end, a that of the leſs, and h the height; then $\overline{A + a + \sqrt{A\,a}} \times \frac{1}{3}\,h$ will be the ſolidity. Hence, 1. If the ends be regular polygons, the rule will be more eaſy, and it is this, as we have above ſtated it; add together the ſquare of a ſide of each end of a fruſtum, and the products of thoſe ſides; multiply the ſum by the height, and the product by the tabular area anſwering to the particular figure of the ends; and $\frac{1}{3}$d of the laſt product will be the content. Or, divide the difference of the cubes of the ſaid ſides by their difference, and multiply the quotient by the height, and the tabular area, and take $\frac{1}{3}$d of the product. 2. If the ends be circles, the fruſtum will be that of a cone, and then multiply ,2618, *viz.* $\frac{1}{3}$d of ,7854, by the height, and the product either by the quotient ariſing from the diviſion of the difference of the cubes of the diameters by the difference of the diameters, or by the ſum ariſing from the addition of the ſquare of each diameter and the product of the diameters, or by the ſum ariſing from the ſquare of the half difference of the diameters added to triple the ſquare of the half ſum. The principles from which theſe rules are deduced will appear under the article PYRAMID.

To find the ſolidity of the ſegment of a ſphere. Rule 1. To three times the ſquare of the radius of its baſe, add the ſquare of its height; multiply the ſum by the height, and the product by ,5236 for the ſolidity. (See *fig.* 92.) Thus, if r = D E the radius of its baſe, and h = G E the height: then $,5236\,h \times \overline{3\,r\,r + h\,h}$ = the ſolidity of the ſegment D G F. Rule 2. From three times the diameter of the ſphere, ſubtract twice the height of the fruſtum; multiply the difference by the ſquare of the height, and the product by ,5236 for the ſolidity. That is, if d = G H the diameter of the ſphere, and h = G E, the height of the fruſtum; then $,5236\,h^2 \times \overline{3\,d - 2\,h}$ = the ſolidity of D G F.

To find the ſolidity of a fruſtum or zone of a ſphere. Add together the ſquares of the radii of the ends and $\frac{1}{3}$d of the ſquare of their diſtance, or of the height: multiply the ſum by the ſaid height, and the product again by 1,5708 for the content. That is, $\overline{R^2 + r^2 + \frac{1}{3}\,h^2} \times \frac{1}{2}\,p\,h$ = the ſolidity of the fruſtum whoſe height is h, and the radii of its ends R and r, p being 3,1416. For the reaſons of theſe rules, ſee SPHERE, or Hutton's Menſuration, p. 206.

To find the content of the fruſtum of a ſpheroid; its ends being perpendicular to one of the axes, and one of them paſſing through the centre. Rule 1. To the area of the leſs end, add twice that of the greater: multiply the ſum by the altitude of the fruſtum; and $\frac{1}{3}$d of the product will be the content. That is, $\overline{2\,D^2 + d^2} \times \frac{1}{3}\,a\,n$ = the fruſtum whoſe ends are perpendicular to the fixed axis; where D is the diameter of the greater end, d that of the leſs, a the altitude, and n = ,785398. And $\overline{2\,T\,C + t\,c} \times \frac{1}{3}\,a\,n$ = the fruſtum whoſe ends are parallel to the fixed axis; where T and C are the tranſverſe and conjugate axes of the greater end, and t and c thoſe of the leſſer end. Here it is evident that the double of the fruſtum will give the content of the zone, or ſpheroidal caſk. Rule 2. From three times the ſquare of the ſemi-axis perpendicular to the ends of the fruſtum, ſubtract the ſquare of the height of the fruſtum; then multiply the difference by $\frac{1}{3}$d of the height, and the product by 3,14159, &c.; and call the laſt product P: then, 1. If the ends be parallel to the fixed axis, ſay, as the revolving axis is to the fixed axis, ſo will P be to the content of the fruſtum. 2. When the ends are perpendicular to the fixed axis, ſay, as the ſquare of the fixed axis is to the ſquare of the revolving axis, ſo is P to the content of the fruſtum. That is, $\frac{3\,f\,f - h\,h}{3\,f\,f} \times p\,h\,r\,r$ will be the fruſtum whoſe ends are perpendicular to the fixed axis: and $\frac{3\,r\,r - h\,h}{3\,r} \times p\,h\,f$, the fruſtum whoſe ends are parallel to the fixed axis; f being the fixed, and r the revolving ſemi-axis, h the height, and p = 3,14159, &c. For the reaſons of theſe rules, ſee SPHEROID, and Hutton, ubi ſupra.

We have a general theorem in Mr. Maclaurin's Treatiſe of Fluxions, concerning the fruſtum of a ſphere, cone, ſpheroid, or conoid, terminated by parallel planes, when compared with a cylinder of the ſame altitude, on a baſe equal to the middle ſection of the fruſtum made by a parallel plane. The difference between the fruſtum and the cylinder is always the ſame in different parts of the ſame,

or of ſimilar ſolids, when the inclination of the planes to the axis, and the altitude of the fruſtum, are given.

In the parabolic conoid this difference vaniſhes, the fruſtum being always equal to a cylinder of the ſame height, upon the ſection of the conoid that biſects the altitude of the fruſtum, and is parallel to its baſes.

In a ſphere, the fruſtum is always leſs than the cylinder by one-fourth part of a right-angled cone, of the ſame height with the fruſtum, or by one half of a ſphere of a diameter equal to that height; and this difference is always the ſame in all ſpheres, when the altitude of the fruſtum is given.

In the cone, the fruſtum always exceeds the cylinder by one-fourth part of the content of a ſimilar cone that has the ſame height with the fruſtum.

In the hyperbolic conoid this exceſs is the ſame as in the cone generated by a triangle $o\,c\,e$, (*fig.* 93) formed by the axis $o\,c$, the aſymptote $o\,e$, and a perpendicular $c\,e$, the altitude of the fruſtum and the inclination of the axis to their baſes being the ſame in both.

In the ſpheroid (*fig.* 94.) the cylinder exceeds the fruſtum; and the difference between them is the ſame as in the cone C D $r\,d$, the plane D $r\,d$, or B $k\,b$, being ſuppoſed parallel to thoſe which terminate the fruſtum. In different inclinations of thoſe planes, when the altitude of the fruſtum is given, that difference is reciprocally as the cube of the diameter B b, which is the conjugate of C A, the axis of the fruſtum. But if the altitude of the fruſtum be alſo varied ſo as to be reciprocally proportional to the diameter B b, then the difference between the fruſtum and cylinder will be always of the ſame magnitude in the ſame ſpheroid or conoid.

When the inclination of the axis of the ſolid to the planes that terminate the fruſtum is given, the difference between the fruſtum and cylinder, in the ſame, or in ſimilar bodies, is as the cube of their common altitude. Maclaurin's Fluxions, Introd. p. 24, 25.

The rules above given, and others of the ſame kind, are of uſe in the menſuration of timber, and alſo in gauging. We ſhall ſubjoin a few examples of their application.

1. How many ſolid feet are there in a tree, whoſe baſes are ſquares, each ſide of the one being 15 inches, and each ſide of the other 6, and the length along the ſide meaſuring 24 feet? (*fig.* 95.)

Here $15 \times 15 = 225$, the greater baſe, and $6 \times 6 = 37$; the leſs, and $15 \times 6 = 90$, their mean. Their ſum is 351, and $\frac{1}{3}$d of it is 117. But A B $-$ D E $= 7\frac{1}{2} - 3 = 4\frac{1}{2}$ $=$ A F, and $\sqrt{\text{A D}^2 - \text{A F}^2} = \sqrt{\overline{24 \times 12}^2 - 4\frac{1}{2}^2}$ $= 287{,}9649$ inches $=$ D F, the perpendicular. Conſequently, $117 \times 287{,}9649 = 33691{,}8933$ inches $= 19{,}49762$ feet $=$ the ſolidity.

2. If a caſk, conſiſting of two equal conic fruſtums joined together at the baſes, have its bung-diameter 28 inches, its head-diameter 20 inches, and length 40 inches; how many gallons of wine will it hold?

Here $20^2 \times {,}7854 = 314{,}16$ = the area at the end,

And $28^2 \times {,}7854 = 615{,}7536$ = the area of the bung circle,

And $20 \times 28 \times {,}7854 = 439{,}824$ = their mean proportion.

Their ſum is 1369,7376

And its third part is 456,5792

which multiplied by 40, the length of both fruſtums together produces 18263,168 ſolid inches, which divided by 231, the inches in a wine gallon, thus,

$$231 = 3 \times 7 \times 11 \left\{ \begin{array}{r} 3) \ 18263{,}168 \\ 7) \ 6087{,}7226 \\ 11) \ 869{,}6746 \end{array} \right.$$

gives 79,0613 wine gallons.

Or, $20^2 + 28^2 + 20 + 28 \times 40 \times 0{,}2618 = 1744 \times 10{,}472 = 18263{,}168$, the ſolidity as before.

3. What is the ſolidity of each of the frigid zones of the earth: the axis being $7957\frac{3}{4}$ miles, and half the breadth, or arc D A, (*fig.* 92.) of the zone being $23\frac{1}{2}$ degrees?

By rule 2. As 1 = tabular radius : $3978\frac{3}{4}$ = radius of the earth, : : ,0829399 = tab. verſed ſine of $23\frac{1}{2}$ degrees : 330,0074946, the verſed ſine or height of the ſegment. Then $,5236\,b^2 \times \overline{3d - 2b} = ,5236 \times 330{,}0074946^2 \times 23213{,}2350108 = 13236797\text{10}$, the content.

By rule 1. As 1 : $3978\frac{3}{4}$: : ,3987491 = tabular ſine of $23\frac{1}{2}$ degrees : 1586,57282526, the radius of the baſe. Then $,5236\,b \times \overline{3r^2 - b^2} = ,5236 \times 330{,}0074946 \times 7660544{,}936 = 1323680299{,}69$, the ſolidity.

4. What is the ſolidity of the fruſtum of a ſphere, the diameter of whoſe great end is four feet, the diameter of the leſs three feet, and the height $2\frac{1}{2}$ feet? Here $\overline{R^2 + r^2 + \frac{1}{3}b^2} \times 1{,}5708\,b = \overline{2^2 + 1{,}5^2 + \frac{1}{3} \times 2{,}5^2} \times 1{,}5708 \times 2\frac{1}{2}$ $= 8\frac{1}{3} \times 3{,}927 = 32{,}725$, the ſolidity of the fruſtum required.

5. What is the ſolidity of each temperate zone of the earth, extending from $23\frac{1}{2}$ degrees to $66\frac{1}{2}$ degrees of latitude, and the diameter of the earth being $7957\frac{3}{4}$ miles? The radius of the top appears by the third example to be 1586,57282526; and as 1 : $3978\frac{7}{8}$: : ,9170601 = tabular ſine of $66\frac{1}{2}$ degrees : 3648,86750538, the radius of the baſe. Alſo the height is 2062,2955. Then $\overline{R^2 + r^2 + \frac{1}{3}b^2} \times 1{,}5708\,b = 17249136 \times 2062{,}2955 \times 1{,}5708 = 55877778668$, the ſolidity of each temperate zone. Otherwiſe; ſince the radii of the ends of this zone are the ſines of $23\frac{1}{2}$ and $66\frac{1}{2}$ degrees, which are complements the one of the other, the ſum of the ſquares of theſe radii will be equal to the ſquare of the radius of the ſphere; and therefore $\overline{\frac{1}{4}dd + \frac{1}{3}bb} \times 1{,}5708\,b = 17249136 \times 2062{,}2955 \times 1{,}5708 = 55877778668$, the content as before.

6. There is a caſk in the form of the middle fruſtum, or zone, of an oblong ſpheroid; the bung-diameter is 30, the head-diameter 18, and the length of the caſk 40 inches; what is the content in ale and wine gallons? Here D $= 30$, $d = 18$, and $a = 40$. Therefore $\overline{2\,\text{D}^2 + d^2} \times \frac{1}{3}\,an = \overline{2 \times 30^2 + 18^2} \times {,}2618 \times 40 = 2124 \times 10{,}472 = 22242{,}528$ = the content in inches. Then, ſince the ale gallon meaſure contains 282 cubic inches, and the wine gallon 231, we have $22242{,}528 \div 231 = 96{,}288$ wine gallons.

7. If the axes of an oblong ſpheroid be 50 and 30, required the content of a fruſtum whoſe ends are perpendicular to the fixed axis, and one of them paſſing through the centre, the height of the fruſtum being 20 inches. Here $\frac{3ff - bb}{3ff} \times phrr = \frac{3 \times 25^2 - 20^2}{3 \times 25^2} \times 3{,}14159 \times 20 \times 15^2 =$ $1475 \times 3{,}14159 \times \frac{12}{5} = 11121{,}23799$ = the content required. For a variety of other examples we refer to Hutton's Menſuration, part iii. § 5. See GAUGING and TIMBER.

FRUTEX. See SHRUB.

FRU-

FRUT ... *Stalks of Plants* are thoſe of a hard, woody ſubſtance.

FRUTIG... *Geography*, a ſmall town of Switzerland, in the canton of Berne, terminating a rich valley, parallel to that of Lauterbruennen, and commencing that of Kander, watered by a river of the ſame name, and bounded by mount Kander. Frutigen gives name to a bailiwick, that was formerly governed by lords of its own, and eſteemed one of the moſt beautiful places in Switzerland, eight miles S. of Spietz, and 30 S. E. of Friburgh.

FRY, in *Ichthyology*, ſignifies the ſpawn, or rather the young of fiſh. See FISH.

FRY's *Bay*, in *Geography*, a bay on the S. W. coaſt of the iſland of Antigua; two miles S. of Reed point.

FRY, *Cape*, a cape in Hudſon's bay. N. lat. 64°. W. long. 88°.

FRYBERG, a town of Bohemia, in the circle of Bechin; nine miles W. of Roſenberg.

FRYBURGH, a poſt town of America, pleaſantly ſituated in York county, Maine, in a bend of Saco river; incorporated in 1777, having a flouriſhing academy, and containing 447 inhabitants. This is the ancient village Pigwaket, through which the upper part of Saco meanders; 60 miles from the ſea, and 120 N. by E. from Boſton. N. lat. 44° 2'. W. long. 70 47 30'.

FRYDUFFRIN, a townſhip of America, in Cheſter county, Pennſylvania.

FRYING-PAN, a dangerous ſhoal, ſo called from its form, lying at the entrance of Cape Fear river in North Carolina; the S. part of it being in N. lat. 33° 32'. W. long. 75°; ſix miles from Cape Fear Pitch, and 24 S. E. by S. from the light-houſe on Bald Head.—Alſo, an iſland in Muddy Lake, Upper Canada, to the northward of Pointe de Tour.

FRYKERYD, a town of Sweden, in Warmeland; 10 miles N. W. of Philipſtadt.

FRYKSANDE, a town of Sweden, in Warmeland; 35 miles N. W. of Philipſtadt.

FRYSOYTA, a town of Germany, in the biſhopric of Munſter; 64 miles N. of Munſter. N. lat. 52° 17'. E. long. 7° 46'.

FRYTH, or FRITH, is explained, by ſir Edward Coke, as a plain between two woods, or a lawn.

Camden uſes it for an arm of the ſea, or a ſtrait between two lands, from *fretum*.

Frith, from the Saxon *frid*, *peace*, is alſo uſed for a wood; becauſe the Engliſh Saxons held woods to be ſacred, and uſed them as ſanctuaries.

FUAGE, or FOCAGE, a tax or impoſition laid on hearths or chimneys, *i. e.* on fire-places, or families, from which was probably derived the *hearth-ſilver*, and *chimney-money*. This duty was repealed by 1 William and Mary, ſeſſ. 1. cap. 10.

Edward the black prince, having Aquitain granted him, laid an impoſition of fuage, or focage, upon the ſubjects of that dukedom, *viz.* one ſhilling for every fire-place. After his example, Charles V. of France laid a tax of a franc for each fire-place, for one year only. His ſucceſſor Charles VI. augmented it under the ſame name. Charles VII. rendered it perpetual, and called it *taille*.

By an ordonnance of Humbert II. dauphin of Viennois, the impoſition of focage, or feuage, was then laid per feu, *i. e.* per fire, or family, *ſeu per lares focum habentes*. In Latin it was called *focagium*, q. d. *pro ſingulis focis*. Sometimes it was alſo called *fournage*, on account of the oven or furnace: in Greek καπνικον or καπνος, *fumus*, *ſmoke*. In Will. Tyr. De Bello Sacro, it is called *foagium*: for it was impoſed by the kings of Jeruſalem. The counts and other lords likewiſe impoſed it on the feudatories, or vaſſals. Zonaras aſſures us, that the general Nicephorus firſt eſtabliſhed it among the Greeks. See CHIMNEY-*money*, and FUMAGE.

FUCA, in *Ichthyology*, a name given by Gaza, and ſome other writers, to the fiſh called phycis by Ariſtotle, Ælian, and other writers; and *tinca marina*, by Salvian and Rondeletius. It is in the Linnæan ſyſtem the BLENNIUS *phycis*. See PHYCIS.

FUCA, *Juan de*, in *Geography*. See JUAN *de Fuca*.

FUCCAGE, a town of Japan, in the iſland of Ximo; 30 miles E. of Nagaſaki.

FUCECCHIO, a town of Etruria, on a lake; 22 miles W. of Florence.

FUCHS, or FUCHSIUS, LEONHARD, in *Biography*, a diſtinguiſhed phyſician and botaniſt of Germany, particularly celebrated for his figures of plants, was born at Wembding, in Bavaria, in the year 1501. He loſt his father when five years old, but his mother, who is repreſented as a woman of very ſuperior talents and virtues, took great care of his education, and was rewarded by the ſucceſs and celebrity of her ſon. After ſtudying the claſſics at Hailbrun and Erfort, he took his firſt degree at the age of 17, with great credit, in the univerſity laſt mentioned. In his 19th year he removed to Ingoldſtadt, in order to profit by the inſtructions of Capnius, and Ceporinus, two profeſſors eminent for their ſkill in the learned languages, and ſtill more for the zeal and honeſty by which, in the dawn of the reformation, they made themſelves obnoxious to the monkiſh faction, by expoſing the corruptions of the church, and promoting a liberal and enlarged ſcheme of education. Fuchſius attached himſelf cloſely to theſe able and enlightened teachers, and while he made a great progreſs in Greek and Latin literature by means of their inſtructions, he imbibed their liberal ſpirit and chriſtian piety. He received the degree of maſter of arts, Jan. 17, 1521, and having ſubſequently applied himſelf with great diligence to the ſtudy of medicine, he was made doctor of phyſic in March 1524, being then about 23 years of age. He had in the mean while become a zealous follower of Luther, and an aſſerter of the authority of the holy ſcriptures alone, in oppoſition to papal power and corruption. Hence he was doubtleſs one of thoſe who gave occaſion to the charge, ſtill renewed from time to time as circumſtances may require, that phyſicians are prone to atheiſm; by which has generally been meant that they are hoſtile to certain impoſitions and corruptions, in which they have no intereſt, but which cannot be entirely concealed from them in the courſe of a learned education. This charge the excellent ſir Thos. Brown and others have thought it worth while, in dark and troubled times, to repel. Happy would it have been had the conduct or character of no phyſician or profeſſed philoſopher, at a more enlightened period, given freſh ſtrength to a calumny that ought to have fallen by its own abſurdity.

Fuchſius ſettled firſt as a phyſician at Munich, where he ſoon after married a young lady of good birth and education, named Anna Fridperger, who bore him four ſons and ſix daughters, and with whom he enjoyed great conjugal felicity till Feb. 1563, when ſhe died. He afterwards married a widow, who ſurvived him. He removed to Ingoldſtadt in May 1526, where he became profeſſor of medicine, but found himſelf ill at his eaſe with reſpect to religion. This induced him to accept the invitation of George, Margrave of Bayreuth, to ſettle at Onoltzbach, about two years afterwards, where he received a handſome ſalary from his patron, who treated him with ſingular reſpect. He was particularly ſucceſsful in the practice of medicine, eſpecially

in

in the treatment of the ſweating ſickneſs, which in 1529 began to rage in Germany. In the courſe of his five years' reſidence at Onoltzbach, Fuchſius publiſhed a Compendium or Introduction to the Practice of Phyſic; the ſixth book of Hippocrates on epidemic diſeaſes, tranſlated from the Greek into Latin, with an ample commentary; an Apology againſt Triverius, a phyſician of Louvain, recommending bleeding on the right ſide in inflammations of the viſcera, eſpecially in pleuriſy; three books of Medical Paradoxes, in which many errors of the Arabian and more recent phyſicians are refuted.

At length, the management of the univerſity of Ingoldſtadt was committed, by William duke of Bavaria, to Leonhard Eccius, a celebrated lawyer, who, knowing the merit of Fuchſius, procured his return to his former profeſſorſhip there in 1533. But he had made himſelf too conſpicuous as a proteſtant, and was too little diſpoſed to aſſimilate his opinions, his manners, or his principles of education to thoſe of the ruling powers, to remain at peace; inſomuch that, notwithſtanding the ſteady patronage of Eccius, he returned in Auguſt of the very ſame year to Onoltzbach, taking refuge for a year afterwards at Culmbach, with the family of the margrave, on account of the peſtilence.

At this period Ulric duke of Wirtemberg, having embraced the reformed religion, was very anxious to induce the moſt learned profeſſors of that faith to eſtabliſh themſelves at his univerſity of Tubingen, in order to render that ſchool an aſylum for all ſuch as were diſpoſed to ſhake off and to expoſe the papal uſurpations. Fuchſius was invited among the reſt, and, on ſettling there in 1535, received an ample ſtipend, as well as the moſt diſtinguiſhed favour from the ſovereign and his ſon prince Chriſtopher. Here he continued in great fame and ſucceſs for 35 years. At length, in his 65th year, he was ſeized with an acute diſeaſe attended with great watchfulneſs, which proved fatal on the 10th of May 1566. He died in the arms of his wife and children, full of faith and fortitude, having in the courſe of his illneſs been obſerved to experience no relief from his ſufferings, but while converſing with his friends on the ſubjects of religion and a future ſtate, which made him forget every thing elſe, and he expreſſed himſelf with all his uſual energy and perſpicuity. He was interred, the day after his death, in a burying ground adjoining to the town, where his firſt wife had been depoſited but little more than three years before.

Some botanical remarks of Fuchſius, relating principally to the Arabian writers, are found in the 2d volume of the *Herbarium* of Brunfelſius. But the work on which his reputation in this line of ſtudy chiefly reſts, is his *Hiſtoria Plantarum*, publiſhed at Baſil in 1542. It conſiſts of one volume in folio, with numerous wooden cuts. A German edition appeared the following year. In this work he chiefly copies Dioſcorides, adding a few remarks of his own, and falling, as Haller obſerves, into the common error of the writers of his time, who expected to find, in their own cold countries, the plants of thoſe more genial climates where the antients ſtudied botany and medicine. The publication of Fuchſius, though nearly on a par with thoſe of other learned men of his time, would probably have been long ſince forgotten, were it not for the tranſcendent merit of its wooden cuts, inferior to thoſe of Brunfelſius alone in execution, and far exceeding them in number. They chiefly indeed conſiſt of pharmaceutical plants, not of rare or difficult ſpecies like the works of Cluſius; but though mere outlines, they are juſtly celebrated for their fidelity and elegance. Theſe original editions are become very rare; but copies and tranſlations of them, various in merit, are common throughout Europe. Amongſt the pooreſt of theſe is a French duodecimo, printed at Lyons, under the title of Le Benefice Commun, in 1555, for which our author is certainly not reſponſible, and it is rather hard in Linnæus to claſs him, on account of ſome ſuch ſpurious editions, under the heads of *monſtroſi* and *rudes* in his *Bibliotheca Botanica*, though indeed he there properly ſtands amongſt the *uſitatiſſimi* with reſpect to his original edition. By ſome of his writings, eſpecially his *Cornarus furens*, publiſhed in 1545 againſt Cornarus, who had attacked his *Hiſtoria Plantarum* in a work entitled *Vulpecula excoriata*, he appears to have been vehement in controverſy, which perhaps is to be attributed more to the temper of the times in which he lived, and the example of the theologians, to whom, nevertheleſs, mankind are ſo much obliged, than to any original malignity of diſpoſition. In any caſe the chief reproach muſt reſt with the aſſailant who uſes ſuch vile weapons, and not with the party who merely defends himſelf; though certainly it is always more magnanimous and politic to repel them in ſilence with the invulnerable ſhield of conſcious ſuperiority. In his general character and deportment Fuchſius is ſaid to have been dignified and amiable, with a fine manly perſon, and a clear ſonorous voice. His piety, temperance, and indefatigable deſire to be uſeful, were alike exemplary. As a lecturer he was peculiarly admired and followed, eſpecially in his anatomical courſes. The famous Veſalius was preſent at one of his lectures, in which he found himſelf criticized. He afterwards familiarly addreſſed the profeſſor, ſaying "why do you attack me who never injured you?" "Are you Veſalius?" exclaimed Fuchſius. "You ſee him before you" replied the former. On which great mutual congratulations enſued, and a ſtrict friendſhip was formed between theſe learned men. Fuchſius was ſo famous throughout Europe, that the great Coſmo duke of Tuſcany invited him, with the offer of a ſalary of 600 crowns, to become profeſſor of medicine at Piſa, which he declined. The emperor Charles V. alſo bore teſtimony to his merit, by ſending him letters with the inſignia of nobility, which honour Fuchſius was ſo far from ſeeking, that he for ſome time declined it. He was indifferent to money, as well as to all other than literary fame. His great ambition was, whenever he undertook in his turn the rectorſhip of the univerſity, to promote good order, induſtry and improvement among the ſtudents, whom he governed with paternal aſſiduity and affection. Two colleges were always under his immediate care, one of them founded by duke Ulric for ſtudents of divinity alone, and more amply endowed by his ſon and ſucceſſor.

Fuchſius left behind him ſeveral unpubliſhed botanical manuſcripts, which received corrections and additions to the lateſt periods of his life, as well as many notes to the medical works he had formerly printed.—Melch. Adami, Vitæ Germ. Med.—Haller. Bibl. Bot. S.

FUCHSIA, in *Botany*, named by Plumier in honour of Leonhard Fuchs, or Fuchſius, of whom an account is given in the preceding article. Plum. Gen. t. 14. Linn. Gen. 53. Schreb. 255. Willd. Sp. Pl. v. 2. 339. Mart. Mill. Dict. v. 2. Dryand. in Ait. Hort. Kew. v. 2. 8. Juſſ. 320. Lamarck, t. 282. (Skinnera; Forſt. Gen. t. 29. Quelusia; Vandell. Fl. Luſit. et Braſil. Specim. 23. t. 2. f. 10. Nahuſia; Schneevoogt, Ic. t. 21.) Claſs and order, *Octandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Onagræ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, funnel-ſhaped, coloured, four-cleft, its ſegments equal, acute, deciduous. *Cor.* Petals four, rarely wanting, equal, inſerted into the rim of the calyx, alternate with its ſegments, and ſhorter. Nectary a notched gland, crowning the germen. *Stam.* Filaments.

Filaments eight, longer than the tube of the calyx, and inſerted into its baſe, thread-ſhaped, four of them uſually ſhorter than the reſt; anthers vertical, two-lobed. *Piſt.* Germen inferior, oval, with four furrows; ſtyle thread-ſhaped, about the length of the ſtamens; ſtigma obtuſe, with four notches. *Peric.* Berry oval, ſucculent, with four furrows and four cells. *Seeds* numerous, ſmall, ovate, ranged vertically in two rows upon the columella in each cell.

Eſſ. Ch. Calyx ſuperior, coloured, four-cleft, bearing the corolla. Petals four. Berry of four cells. Seeds numerous.

Obſ. Linnæus, relying on Plumier's figure, has miſtaken the calyx for a corolla, which he therefore deſcribes as having eight marginal ſegments, and, owing to a further inaccuracy in the delineations of his original author, or at leaſt in the engraved copies of them, he was induced to refer the genus erroneouſly to his fourth claſs inſtead of the eighth. Hence the real *Fuchſia* being widely miſunderſtood, ſome of its congeners have been eſtabliſhed, by various names, as diſtinct genera; witneſs the above ſynonyms. We ſhall attempt a more complete enumeration and diſcrimination of the ſpecies than have hitherto been given. They are among the moſt elegant of all plants, though, as far as we know, not enriched with any fragrance, nor with any valuable medicinal or economical properties.

1. F. *triphylla*. Linn. Sp. Pl. 159. (F. triphylla, flore coccineo; Plum. Ic. t. 133. f. 1.)—Cluſter terminal, naked. Leaves entire. Stem ſimple, erect.—Native of the Weſt Indies, but it ſeems to be very rare. Plumier does not mention where he found this ſpecies, nor has any other perſon, as far as we can diſcover, met with it, except Thierry de Menonville, a ſpecimen from whom, gathered in Hiſpaniola, was given by Thouin to the younger Linnæus, along with about 1200 of the fineſt and rareſt plants, gathered by various French voyagers. The *ſtem* of this, the original ſpecies of *Fuchſia*, appears to be ſimple, herbaceous and erect. The *leaves* are three together in a whorl, ſeſſile, oblong, about two inches in length, roughiſh, nearly entire, turned of a greyiſh brown by drying. *Flowers* in a ſimple, terminal, upright cluſter, their calyx about an inch and half long, ſcarlet as well as the petals, which colour remains in the dried ſpecimen. *Berry* almoſt globular, rather larger than a common black currant.

2. F. *ſimplicicaulis*. Ruiz and Pavon Fl. Peruv. v. 3. 89. t. 322. f. *a*.—Umbel terminal, of four flowers. Involucrum ſomewhat downy, four-leaved. Leaves lanceolate, toothed, ſmooth. Stem ſimple, drooping. Native of the woods of Munna in Peru, flowering in Auguſt and September. *Stem* rather ſhrubby, four feet high, ſimple, except now and then a radical ſhoot or two, leafy, drooping at the ſummit. *Leaves* four in a whorl, nearly ſeſſile, linear-lanceolate, ſlightly toothed, drooping, very ſmooth. *Stipulas* intrafoliaceous, minute, deciduous. *Flowers* four together, drooping, forming a terminal umbel, with an involucrum of four ovate, pointed, toothed, rather downy, leaves. The umbel is ſometimes proliferous. *Calyx* roſe-coloured, downy, rather larger than in the former, and with longer teeth. *Petals* ſcarlet.

3. F. *apetala*. Ruiz and Pavon Fl. Peruv. v. 3. 89. t. 322. f. *b*.—Flower-ſtalks corymboſe, terminal and axillary. Leaves ſcattered, ovate, entire. Petals wanting.—Plentiful in the woods of Huaſſahuaſſi and Munna in Peru, flowering in October and November. *Stem* ſhrubby, paraſitical on the trunks of trees, downy, branched. *Leaves* alternate or ſcattered, ſtalked, ovate, entire, ſomewhat wavy, ſoft, and tender, ſcarcely an inch and half long. *Flowers* large, drooping, remarkable for having no petals. *Calyx* red, three inches in length. *Berry* red.

4. F. *roſea*. Ruiz and Pavon Fl. Peruv. v. 3. 88. "Flower-ſtalks axillary, ſingle-flowered. Leaves faſciculate, unequal and alternate, lanceolate, entire."—Found on precipices at the port of Valparaiſo in Chili, flowering in October and November. *Stem* ſhrubby, 10 or 12 feet high, erect, round, branched. *Branches* brittle. *Leaves* eight from one centre, unequal, ſtalked, lanceolate, entire, ſmooth; the upper ones alternate. *Flowers* drooping, with roſe-coloured petals and calyx. Of this no figure is given in the *Flora Peruviana*, ſo we can only copy the deſcription as above.

5. F. *ferratifolia*. Ruiz and Pavon Fl. Peruv. v. 3. 86. t. 323. f. *a*.—Flower-ſtalks axillary. Leaves three or four in a whorl, ovate, ſtalked, ſerrated, ſmooth above, as long as the flowers.—Found in moiſt ſhady places at Munna in Peru, flowering from June to September, when it makes a very ornamental appearance. The *ſtem* is ſhrubby, two or three ells high, not much branched. *Leaves* either oppoſite, or three or four in a whorl, three to five inches long and one or two broad, ſpreading, ſlightly downy beneath, with numerous red veins, and red ſtalks. *Flowers* pendulous from each axilla, rather ſmaller than thoſe of *F. apetala*, with a roſy-red, rather downy calyx, and ſcarlet petals. The tips of the calyx however are green. *Berry* purpliſh, elongated.

6. F. *denticulata*. Ruiz and Pavon Fl. Peruv. v. 3. 87. t. 325. f. *b*.—Flower-ſtalks axillary, reaching beyond the branches. Leaves three in a whorl, ſtalked, elliptic-lanceolate, toothed, ſhorter than the flowers.—Native of ſunny precipices and banks at Huaſſahuaſſi and Cheuchin in Peru, blooming beautifully from March to October. This is a *ſhrub* about the ſize of the laſt, from which it differs in the toothed, not ſerrated, *leaves*, and in the extenſion of the *flowers* beyond the ends of the branches, their ſtalks proceeding from the boſoms of ſome of the upper leaves only. The *calyx* is purple. *Petals* rounded, ſcarlet. *Stamens* and *ſtyle* purple, not ſcarlet like the former. *Berry* purple.

7. F. *ovalis*. Ruiz and Pavon Fl. Peruv. v. 3. 87. t. 324. f. *a*.—Flower-ſtalks in leafy whorls, on ſimple axillary branches. Leaves oppoſite or three together, ſtalked, elliptical, wavy, downy on both ſides. Calyx hairy. Native of the woods of Munna in Peru, flowering from June to Auguſt. A *ſhrub* about ſix feet high, upright and branched. The *leaves* are three inches long, broadly elliptical, acute, on downy ſtalks. *Flowering branches* ſhorter than the leaves, round, ſimple, downy, each bearing two or three whorls of ſmall downy leaves, with a correſponding number of axillary ſimple flower-ſtalks. The *calyx* is not above an inch long in the tube, ſcarlet, hairy externally, like the germen and ſtalk. *Petals* ſcarlet, acute.

8. F. *corymbiflora*. Ruiz and Pavon Fl. Peruv. v. 3. 87. t. 325. f. *a*.—Cluſter terminal, leafy, drooping. Leaves elliptic-lanceolate, nearly entire, downy. Calyx downy. Native of ſhady groves at Chincao and Munna in Peru, flowering in Auguſt and September.—A downy *ſhrub*, ſix feet high, but little branched. *Leaves* oppoſite, ſtalked, ovate or elliptic-lanceolate, pointed, very obſcurely toothed, two or three inches long. *Flowers* about the ſize and colour of the firſt ſpecies, and, as in that, forming a whorled cluſter, but drooping, downy, and accompanied at the baſe of each partial ſtalk with a ſmall, ovate, downy leaf or bractea. *Berry* purpliſh-red, hairy.

9. F. *coccinea*. Dryandr. in Ait. Hort. Kew. v. 2. 8. Willd. Sp. Pl. v. 2. 340. Curt. Mag t. 97. (F. macroſtema; Ruiz

Ruiz and Pavon Fl. Peruv. v. 3. 88. t. 324. f. *b.* Nahuſia coccinea; Schneevoogt Ic. t. 21. T'hilco; Feuillée Voy. v. 3. 64. t. 47.)—Flower-ſtalks axillary, longer than the leaves, drooping. Leaves oppoſite or whorled, ſtalked, ovate, toothed, ſmooth. Teeth of the calyx as long as its tube.—Native of Chili, in mountainous marſhy ſituations, flowering from June to April. A *ſhrub* from three to ſix feet high, ſmooth in all its parts, very much branched. *Leaves* two or three, rarely four, together, ſcarcely above an inch, or inch and half, in length, rather diſtantly toothed; paler and ſhining beneath. *Flower-ſtalks* longer than the leaves. *Calyx* ſcarlet, with a much ſhorter tube than any of the preceding. *Petals* violet, obovate and blunt. *Stamens* and *ſtyle* ſcarlet, hanging far out of the flower. *Berry* dark purple. The flowers are reported to be ſometimes five-cleft and decandrous, of which we have never ſeen an inſtance, and we much doubt whether it be not an error, originating with Feuillée. The people of Chili call this ſhrub T'hilco and Chilco, and uſe it, in decoction or infuſion, as a cooling medicine in inflammatory fevers. The wood is excellent for dyeing black. A plant of this ſpecies, apparently in a dead ſtate, was brought by Captain Firth in 1788 to Kew garden, from Liſbon, and it was ſaid to have come from the Brazils. As the ſpring advanced, it began to ſprout, and ſoon put forth its exquiſitely beautiful flowers, to the admiration of all who beheld it. It is now become very common, being eaſily encreaſed by cuttings, and thriving equally well in a ſtove, green-houſe or frame. The root ſtands our winters in the open ground, though the ſtems periſh, but as they ſhoot up again, and flower with peculiar luxuriance in the ſummer and autumn, this is perhaps the beſt mode of treatment. When gathered, this plant ſoon withers, its evaporation being very rapid.

10. F. *decuſſata.* Ruiz and Pavon Fl. Peruv. v. 3. 88. t. 323. f. *b.*—Flower-ſtalks axillary, longer than the leaves, pendulous. Leaves oppoſite or whorled, elliptic-lanceolate, ſlightly toothed, downy. Teeth of the calyx nearly as long as its tube.—Native of ſhady moiſt places at Munna in Peru, flowering from July to September.—A *ſhrub* about three feet high, apparently very nearly related to the laſt, from which it differs in the downineſs, and taper baſes of its *leaves*, its ſcarlet, more acute *petals*, and red *fruit*.

11. F. *lycioïdes.* Andr. Repoſ. t. 120.—Flower-ſtalks axillary, ſhorter than the leaves, drooping, Leaves ſcattered, elliptic-lanceolate, wavy. Teeth of the calyx as long as its tube, reflexed.—Native of the north-weſt coaſt of America, from whence it was introduced to our gardens, according to Mr. Andrews, in 1796. It is leſs ornamental than any of the above deſcribed, though not inelegant in its *flowers*, which, as well as the *leaves*, bear ſome reſemblance to a *Lycium*. The *calyx* is of a dull or pale red, and remarkable for being reflexed. *Petals* purple, about as long as the ſtamens, but ſhorter than the ſtyle. *Berry* blackiſh. It is increaſed by cuttings, but is more tender than the far more deſirable *F. coccinea.* We are at a loſs for the foundation of Mr. Andrews's "doubts whether this ſpecies may not be the *F. triphylla* of Father Plumier," as the figure of the latter ſtrikingly ſhews their wide difference.

12. F. *excorticata.* Linn. Suppl. 217. Willd. Sp. Pl. v. 2. 340. (Skinnera excorticata; Forſt. Prod. 27.)—Flower-ſtalks axillary, ſhorter than the leaves, drooping. Leaves elliptic-lanceolate, toothed, hoary beneath. Teeth of the calyx ſhorter than the tube, ſpreading.—Native of New Zealand. A *tree* ſmooth in all its parts. The *trunk* is two or three inches in diameter. *Leaves* ſcattered, ſtalked, two inches long, varying in breadth, deciduous. *Flowers* larger than in *F. lycioides*, but ſomewhat like them in the colour of the calyx, whoſe teeth however are of a ſhorter proportion, and not reflexed. The *petals* are ſmall, acute, deep violet.

We might ſwell our liſt of ſpecies with *F. multiflora*, taken up by Willdenow from the *Mantiſſa* of Linnæus, p. 331, on the authority of Mutis, who merely mentioned to him that there were two ſpecies of this genus in Mexico, one with many flowers on a ſtalk, the other with ſingle-flowered peduncles; but we preſume the former muſt be included among thoſe we have adopted from the *Flora Peruviana.* It is much to be wiſhed that the Spaniſh botaniſts might introduce any of them to the gardens of Europe.

Fuchsia, in *Gardening*, comprehends plants of the flowery exotic kind for the ſtove; of which the ſpecies chiefly cultivated are, the three-leaved fuchſia (F. triphylla) and the ſcarlet-flowered fuchſia (F. coccinea). The firſt is an herbaceous plant of ſmall growth, but the latter a ſhrub of conſiderable ſize with beautiful ſcarlet flowers.

Method of Culture.—Both theſe plants are capable of being increaſed by ſowing the ſeeds, by laying the young ſhoots down, by cuttings made from the ſhoots, and even ſometimes by ſuckers taken from the roots.

The ſeeds ſhould be ſown in pots filled with good light mould in the early ſpring plunging them in a bark hot-bed. When the plants come up, they muſt be kept clean, being occaſionally refreſhed with a little water. As ſoon as they have attained a few inches in height, they ſhould be carefully ſhaken out of the old pots, and after being nicely ſeparated, be planted out in ſeparate ſmall pots filled with the ſame ſort of mould, being replunged in the bark hot-bed, and kept well ſhaded until they have taken freſh root, when they ſhould have air admitted pretty freely.

The plants require to be kept warm during the winter ſeaſon.

The layers, cuttings and ſuckers may be laid down or be planted out towards the end of the ſummer or the beginning of autumn, in pots for the purpoſe, being occaſionally watered, and placed in the hot-bed.

The plants ſhould be kept in the ſtove during the winter ſeaſon, but they may be ſet out in the green-houſe in the ſummer months, when they will afford much ornament in their beautiful ſcarlet flowers, as they continue for a conſiderable length of time.

FUCHSWINKE, in *Geography*, a town of Sileſia, in the principality of Neiſſe; three miles S. of Patſchkau.

FUCINUS Lacus, in *Ancient Geography*, a lake of Italy in the Apennine mountains, belonging to the country of the Marſi. It is now called lake Celano. For a particular account of it, ſee Celano.

FUCUS is uſed for a paint, or compoſition, applied on the face, to beautify it, and heighten the complexion.

Old women make uſe of fucuſes and pomatums, to appear young. The fucus made with ceruſſe is corroſive and pernicious to the ſkin.

Pliny ſays, that the fucus of the Roman dames was a kind of white earth, or chalk, brought from Chio and Samos, diſſolved in water.

The fucus Solimanni is a compoſition of prepared ſublimate, in great repute among the Spaniards of Peru.

Fucus *Giganteus*, a name given by Mr. Banks and Dr. Solander to a kind of ſea-weed of an enormous ſize, which they diſcovered in their paſſage from Rio de Janeiro to the ſtrait of Le Maire. The leaves of it were four feet long, and ſome of the ſtalks, though not thicker than a man's thumb, above one hundred and twenty.

Fucus, in *Botany*, (from φυκος a ſea-weed, ſome kinds of which being uſed in colouring, occaſioned the Latin

word *fucare*, to ſtain or paint.) Linn. Gen. 567. Schreb. 768. Juſſ. 6. Reaumur Mem. de l'Acad. des Sciences for 1711, 282. t. 9, 10, 11. Claſs and order, *Cryptogamia Algæ*. Nat. Ord. *Algæ*.

Gen. Ch. Male unknown. Female, *Cal.* and *Cor.* none. *Piſt.* Germen imbedded in the gelatinous internal ſubſtance of a membranous or coriaceous frond, aggregate; ſtyle and ſtigma unknown. *Peric.* gelatinous. *Seeds* roundiſh, numerous, cluſtered, at length diſperſed.

Eſſ. Ch. Seeds produced in cluſtered tubercles, which burſt at their ſummits.

The fructification of this genus ſtill remains in the greateſt obſcurity. Linnæus imagined the male flowers to reſide in the ſpongy fibres found in the air-bladders of ſome ſpecies; but this appears to be merely cellular ſubſtance, thoſe bladders ſerving only to float the plant. Yet this theory, founded on a miſapprehenſion of Reaumur's opinion, is adopted by Juſſieu. Reaumur thought certain fibrous tufts, ſcattered over the ſurface, were male flowers. Gærtner has recurred to the old opinion that the family of ſea-weeds, and ſome others of the *Cryptogamia*, have no actual ſexual impregnation; but this does not bring us at all nearer the truth, though it may ſerve to ſhelter our ignorance. Mr. Correa de Serra, in the Philoſophical Tranſactions for 1796, has ſuggeſted that the mucus which envelopes the ſeeds of this family may be the true pollen or impregnating matter, which ſeems to us the moſt probable conjecture, though col. Velley, in the fifth volume of the Linnæan Society's Tranſactions, has oppoſed it. A great difficulty reſpecting, not only the generic character, but in many caſes the ſpecific diſcrimination of theſe plants, ariſes from the different aſpects the fruit aſſumes, being ſometimes in the form of round many-ſeeded tubercles, ſometimes in that of widely diſperſed ſeeds, like thoſe of an *Ulva*. This takes place unqueſtionably in the very ſame ſpecies. Theſe difficulties are ſo great, that though Roth and others have attempted generic diſtinctions among the plants ranged previouſly under *Fucus* and *Conferva*, Mr. Dawſon Turner, author of an excellent ſynopſis of the Britiſh *Fuci*, and of a ſplendid and very learned general work on this genus with coloured plates, in which 134 ſpecies have already appeared, leaves the ſubject of the generic character in complete uncertainty. The beſt books on the ſpecies of *Fucus* are Gmelin's *Hiſtoria Fucorum*, publiſhed at Peterſburgh, in 1768; Eſper's *Icones Fucorum*, Nuremberg 1800; Goodenough and Woodward's Obſervations on the Britiſh Fuci, Tr. of Linn. Soc. v. 3, beſides the works of Mr. Turner above-mentioned, and the ſplendid faſciculi of Stackhouſe's *Nereis Britannica*, and of Velley's *Plantæ Marinæ*. Numerous ſpecies are alſo figured and deſcribed in the Engliſh Botany. Thoſe which are natives of the Britiſh ſhores are now ſuppoſed to amount to near 100. They are diſtributed into the following ſections. 1. Leaves, or rather leaflets, diſtinct. 2. Leaves united with the ſtem. 3. Winged, or having a rib running along the centre of the leaf or frond. 4. Frond flat and deſtitute of a rib. 5. Frond compreſſed. 6. Frond round or cylindrical.

Theſe plants are eaſily preſerved, by being firſt waſhed clean from ſea water, and then diſplayed on paper while floating in a pan of freſh water, during which they are readily diſplayed by means of a briſtle, or hair-pencil. Some of them adhere to the paper when dry, others ſtart from it. Many ſpecies make a very elegant appearance, and are favourites with collectors of natural productions.

Fucus, in the teſtaceous claſs of *Vermes*, a ſpecies of *Murex*, which ſee.

Fucus, in the zoophyte claſs of *Vermes*, a name given by Imperatori to the Gorgonia *verrucoſa*, which ſee.—Alſo, to ſeveral ſpecies of *Alcyonium*, *Tubularia*, and *Corallines*, which ſee.

Fucus *palmatus*, *handed fucus*, the name given to a ſpecies of ſea fucus, diſtinguiſhed from the reſt by its having no ſtalks, its leaves being divided in the manner of a hand, and its extremities divided into many curled ſegments. It is common on almoſt all the ſea coaſts of Europe, and is one of the ſeveral ſpecies of ſea ſubſtances in which Mr. Reaumur has diſcovered regular flowers and ſeeds. They are in this ſpecies however ſo ſmall, as to require the aſſiſtance of a microſcope to diſcover them; though after they have been once ſeen in that manner, as is the caſe in many microſcopic objects, they may then be eaſily diſtinguiſhed by the naked eye. This ſubſtance is faſtened to ſome ſtone by a round root, from which there ariſe four or five leaves, which at about an inch diſtance from the root divide into a number of branchings, which conſtitute the whole of it. The natives of New Holland broil this ſpecies of ſea-wreck and eat it. It is alſo eaten both in Scotland and Ireland, ſometimes freſh, as a ſallad; but more frequently it is dried, rolled together, and chewed as tobacco. In the iſle of Sky it is uſed as a medicine.

Fucus *polyſchides*. See Polyschides.

Fucus *thermalis*, the name of a remarkable ſubſtance found only in the hot-water ſprings. It was firſt diſcovered by Monſ. de Monteſquieu, in the great baſon, at the boiling ſpring in Gaſcony; he was not able to diſcover that it produced either flowers or ſeeds. Its ſubſtance is entirely compoſed of ſmall bladders full of air, the ſurfaces of which are reticular, as worked in the manner of coarſe canvas. It is obſerved to grow only in the hotteſt waters.

FUDAL Baha, in *Geography*, a mountain of Aſiatic Turkey, in Natolia; ten miles from Cogni.

FUDDAH, a river of Algiers, which runs into the Shellif; five miles E. of Sinaab.

FUDDER, among the *Miners*, a load of lead, which is eight pigs, or ſixteen hundred weight. See Fodder.

FUDIA, in *Geography*, one of the Weſtern iſlands of Scotland, which is ſmall and mountainous. N. lat. 57° 2'. W. long. 7° 23'.

FUE'. See Faoue'.

FUEGO. See Terra *del Fuego*.

Fuego, Fogo, or *St. Philip*, one of the cape Verd iſlands. The firſt of theſe names is derived from a volcano, and the laſt from its being diſcovered on St. Philip's day. The volcano iſſues from a high mountain, and throws out flames, which are viſible at a great diſtance in the night; alſo clouds of aſhes, which ſuffocate cattle, pumice-ſtones, which float on the ſea, and torrents of ſulphur. The iſland has neither rivers nor freſh water; nevertheleſs it is fertile in maize, gourds, water-melons, wild figs, oranges, and apples. It abounds with goats, which run wild upon the mountains, the ſkins of which yield a revenue to the crown. They export alſo the ſkins of cattle, horſes, aſſes, and hogs. Fuego is about 15 miles in length. N. lat. 14° 57' 18". W. long. 24° 22' 12".

FUEGOO, one of the Philippine iſlands, about 36 miles in circumference; in the centre the land is pretty high, and declines towards both ends. N. lat. 9° 20'. E. long. 123° 26'.

FUEL, in *Philoſophy*, the pabulum of fire, or whatever receives and retains fire, and is conſumed, or rendered inſenſible thereby.

A great deal of nicety is required in chooſing the proper fuel to raiſe and continue the ſeveral degrees of fire in chemical operations. Dr. Black divides fuels into five

claſſes; the firſt comprehends the fluid inflammable bodies; the ſecond, peat or turf; the third, charcoal of wood; the fourth, pit-coal charred; and the fifth, wood, or pit-coal, in a crude ſtate, and capable of yielding a copious and bright flame.

The fluid inflammables are conſidered as diſtinct from the ſolid, on this account, that they are capable of burning upon a wick, and become in this way the moſt manageable ſources of heat; though, on account of their price, they are never employed for producing it in great quantities; and are only uſed when a gentle degree, or a ſmall quantity of heat is ſufficient. The ſpecies which belong to this claſs are alcohol and different oils.

The firſt of theſe, alcohol, when pure and free of water, is as convenient and manageable a fuel for producing moderate or gentle heats as can be deſired. Its flame is perfectly clean, and free from any kind of ſoot; it can eaſily be made to burn ſlower or faſter, and to produce leſs or more heat, by changing the ſize or number of the wicks upon which it burns; for as long as theſe are fed with ſpirit, in a proper manner, they continue to yield flame of preciſely the ſame ſtrength. The cotton, or other materials, of which the wick is compoſed, is not ſcorched or conſumed in the leaſt, becauſe the ſpirit with which it is conſtantly ſoaked is incapable of becoming hotter than 174°, Fahrenheit, which is conſiderably below the heat of boiling water. It is only the vapour that ariſes from it which is hotter, and this too only in its outer parts, that are moſt remote from the wick, and where only the combuſtion is going on, in conſequence of communication and contact with the air. At the ſame time, as the alcohol is totally volatile, it does not leave any fixed matter which, by being accumulated on the wick, might render it foul and fill up its pores. The wick, therefore, continues to imbibe the ſpirit as freely, after ſome time, as it did at the firſt. Theſe are the qualities of alcohol as a fuel. But theſe qualities belong only to a ſpirit that is very pure. If, on the contrary, it be weak, and contain water, the water, being leſs volatile, does not evaporate ſo faſt from the wick as the more ſpirituous part; and the wick becomes, after ſome time, ſo much ſoaked with water that it does not imbibe the ſpirit properly. The flame becomes much weaker, or is altogether extinguiſhed. When alcohol is uſed as a fuel, therefore, it ought to be made as ſtrong, or free from water, as poſſible.

Oil, although fluid like ſpirit of wine, and capable of burning in a ſimilar manner, is not ſo convenient in many reſpects. It is diſpoſed to emit ſoot; and this applying itſelf to the bottom of the veſſel expoſed to it, and, increaſing in thickneſs, forms, by degrees, a ſoft and ſpongy medium, through which heat is not ſo freely and quickly tranſmitted. This was obſerved by Muſchenbroeck in his experiments upon the expanſions of metalline rods heated by lamps. It is true we can prevent this entirely, by uſing very ſmall wicks, and increaſing the number, if neceſſary, to produce the heat required. Or, we may employ one of thoſe lamps, in which a ſtream of air is allowed to riſe through the middle of the flame, or to paſs over its ſurface with ſuch velocity as to produce a more complete inflammation than ordinary. But we ſhall be as much embarraſſed in another way, for the oils commonly uſed, being capable of aſſuming a heat greatly above that of boiling water, ſcorch and burn the wick, and change its texture, ſo that it does not imbibe the oil ſo faſt as before. Some have attempted a remedy, by making the wick of incombuſtible materials, as aſbeſtos, or wire; but ſtill, as the oil does not totally evaporate, but leaves a ſmall quantity of groſs fixed carbonaceous matter, this, conſtantly accumulating, clogs the wick to ſuch a degree, that the oil cannot aſcend, the flames become weaker, and, in ſome caſes, are entirely extinguiſhed. There is, however, a difference among the different oils in this reſpect; ſome being more totally volatile than others. But the beſt are troubleſome in this way, and the only remedy is to change the wicks often, though we can hardly do this and be ſure of keeping always an equal flame.

The ſecond kind of fuel mentioned, peat, is ſo ſpongy that, compared with the more ſolid fuels, it is unfit to be employed for producing very ſtrong heats. It is too bulky for this: we cannot put into a furnace, at a time, a quantity that correſponds with the quick conſumption that muſt neceſſarily go on when the heat is violent. There is, no doubt, a great difference in this reſpect among different kinds of this fuel; but this is the general character of it. However, when we deſire to produce and keep up, by means of cheap fuel, an extremely mild gentle heat, we can hardly uſe any thing better than peat. But it is beſt to have it previouſly charred, that is, ſcorched, or burnt to black coal. When prepared for uſe in that manner, it is capable of being made to burn more ſlowly and gently, or will bear, without being extinguiſhed altogether, a greater diminution of the quantity of air, with which it is ſupplied, than any other of the ſolid fuels. Dr. Boerhaave found it extremely convenient and manageable in his Furnus Studioſorum.

The next fuel, in order, is the charcoal of wood. This is prepared by piling up billets of wood into a pyramidal heap, with ſeveral ſpiracles, or flues, formed through the pile. Chips and bruſhwood are put into thoſe below, and the whole is ſo conſtructed that, when kindled, it kindles almoſt over the whole pile in a very ſhort time. It would burſt out into a blaze, and be quickly conſumed to aſhes, were it not covered all over with earth, or clay, beaten cloſe, leaving openings at all the ſpiracles. Theſe are carefully watched; and, whenever the white watery ſmoke is obſerved to be ſucceeded by thin blue, and tranſparent ſmoke, the whole is immediately ſtopped; this being the indication of all the watery vapour being gone, and the burning of the true coaly matter commencing. Thus is a pretty ſtrong red heat raiſed through the whole maſs, and all the volatile matters are diſſipated by it, and nothing now remains but the charcoal. The holes being all ſtopped in ſucceſſion, as this change of the ſmoke is obſerved, the fire goes out for want of air. The pile is now allowed to cool. This requires many days; for, charcoal being a very bad conductor of heat, the pile long remains red hot in the centre, and, if opened in this ſtate, would inſtantly burn with fury.

Small quantities may be procured at any time, by burning wood in cloſe veſſels. Little pieces may be very finely prepared, at any time, by plunging the wood in lead melted and red hot.

This is the chief fuel uſed by the chemiſts abroad, and has many good properties. It kindles quickly, emits few watery or other vapours while burning, and when conſumed leaves few aſhes, and thoſe very light. They are, therefore, eaſily blown away, ſo that the fire continues open, or pervious to the current of air which muſt paſs through it to keep it burning. This ſort of fuel, too, is capable of producing as intenſe a heat as can be obtained by any; but in thoſe violent heats it is quickly conſumed, and needs to be frequently ſupplied.

Foſſil coals charred, called cinders, or coaks, have, in many reſpects, the ſame properties as charcoal of wood; as kindling more readily in furnaces than when they are not charred, and not emitting watery, or other groſs ſmoke,

while

while they burn. This ſort of charcoal is even greatly ſuperior to the other in ſome properties.

It is a much ſtronger fuel, or contains the combuſtible matter in greater quantity, or in a more condenſed ſtate. It is, therefore, conſumed much more ſlowly on all occaſions, and particularly when employed for producing intenſe melting heats. The only inconveniences that attend it are, that, as it conſumes, it leaves much more aſhes than the other, and theſe much heavier too, which are, therefore, liable to collect in ſuch quantity as to obſtruct the free paſſage of air through the fire; and further, that when the heat is very intenſe theſe aſhes are diſpoſed to melt or vitrify into a tenacious droſſy ſubſtance, which clogs the grate, the ſides of the furnace and the veſſels. This laſt inconvenience is only troubleſome, however, when the heat required is very intenſe. In ordinary heat the aſhes do not melt, and though they are more copious and heavy than thoſe of charcoal of wood, they ſeldom choke up the fire conſiderably, unleſs the bars of the grate be too cloſe together.

This fuel, therefore, is preferable, in moſt caſes, to the charcoal of wood, on account of its burning much longer, or giving much more heat before it is conſumed. The heat produced, by equal quantities, by weight, of pit-coal, wood-charcoal and wood itſelf, are nearly in proportion of 5, 4, and 3. The reaſon why both theſe kinds of charcoal are preferred, on moſt occaſions, in experimental chemiſtry, to the crude wood, or foſſil coal, from which they are produced, is, that the crude fuels are deprived, by charring, of a conſiderable quantity of water, and ſome other volatile principles, which are evaporated during the proceſs of charring, in the form of ſooty ſmoke or flame. Theſe volatile parts, while they remain in the fuel, make it unfit (or leſs fit) for many purpoſes in chemiſtry. For beſides obſtructing the vents with ſooty matter, they require much heat to evaporate them; and, therefore, the heat of the furnace, in which they are burnt, is much diminiſhed and waſted by every addition of freſh fuel, until the freſh fuel is completely inflamed, and reſtores the heat to its former ſtrength.

But theſe great and ſudden variations of the heat of a furnace are quite inconvenient in moſt chemical proceſſes. In the greater number of chemical operations, therefore, it is much more convenient to uſe charred fuel, than the ſame fuel in its natural ſtate.

There are, at the ſame time, ſome kinds of foſſil coal, which are exceptions to what has now been delivered in general. We meet with ſome of them that leave a ſmaller proportion of aſhes than others, and the aſhes of ſome are not ſo liable to melt in violent heats. There is one ſpecies too, ſuch as the Kilkenny coal of Ireland, and which occurs likewiſe in ſome parts of this country, that does not contain any ſenſible quantity of water, or other ſuch volatile principles. But this may be called a ſort of native charcoal. It has the appearance of ordinary coal, but, when thrown into the fire, does not emit ſmoke or ſoot. It merely becomes red, gives a ſubtile blue flame, and conſumes like charcoal; only it laſts ſurprizingly long, or continues to give heat for a very long time before it is totally conſumed. But it cannot be made to burn ſo as to produce a gentle heat. If not in conſiderable quantity, and violently heated, it is ſoon extinguiſhed.

In uſing this kind of fuel, it is proper to be on our guard againſt the dangerous nature of the burnt air, which ariſes from charcoal of all kinds. Charcoal burns without viſible ſmoke. The air ariſing from it appears to the eye as pure and as clear as common air. Hence it is much uſed abroad by thoſe who are ſtudious of neatneſs, and cleanlineſs in their apartments. But this very circumſtance ſhould make us more watchful againſt its effects, which may prove dangerous, in the higheſt degree, before we are aware of it. The air ariſing from common crude fuel is no doubt as bad, but the ſmoke renders it diſagreeable before it becomes dangerous. The firſt ſenſation is a ſlight ſenſe of weakneſs; the limbs ſeem to require a little attention, to prevent falling. A ſlight giddineſs, accompanied by a diſtinct feeling of a flush, or glow in the face and neck. Soon after, the perſon becomes drowſy, would ſit down, but commonly falls on the floor inſenſible of all about him, and breathes ſtrong, ſnoring as in an apoplexy. If the perſon is alarmed in time, and eſcapes into the open air, he is commonly ſeized with a violent head-ach, which gradually abates.

But when the effect is completed, as above deſcribed, death very ſoon enſues, unleſs relief be obtained. There is uſually a foaming at the mouth, a great flush or ſuffuſion over the face and neck, and every indication of an oppreſſion of the brain, by this accumulation of blood. The moſt ſucceſsful treatment is to take off a quantity of blood immediately, and throw cold water on the head repeatedly. A ſtrong ſtimulus, ſuch as hartſhorn, applied to the ſoles of the feet, has alſo a very good effect.

The fifth and laſt kind of fuel is wood, or foſſil coals, in their crude ſtate, which it is proper to diſtinguiſh from the charcoals of the ſame ſubſtances. The difference conſiſts in their giving a copious and bright flame, when plenty of air is admitted to them, in conſequence of which they muſt be conſidered as fuels very different from charcoal, and adapted to different purpoſes. See FLAME.

Flaming fuel cannot be managed like the charcoals. If little air be admitted, it gives no flame, but ſooty vapour, and a diminution of heat. And if much air be admitted to make thoſe vapours break out into flame, the heat is too violent. Theſe flaming fuels, however, have their particular uſes, for which the others are far leſs proper. For it is a fact, that flame, when produced in great quantity, and made to burn violently, by mixing it with a proper quantity of freſh air, by driving it on the ſubject, and throwing it into whirls and eddies, which mix the air with every part of the hot vapour, gives a moſt intenſe heat. This proceeds from the vaporous nature of flame, and the perfect miſcibility of it with the air.

As the immediate contact and action of air are neceſſary to the burning of every combuſtible body; ſo the air, when properly applied, acts, with far greater advantage on flame, than on the ſolid and fixed inflammable bodies: for when air is applied to theſe laſt, it can only act on their ſurface, or the particles of them that are outermoſt; whereas flame being a vapour or elaſtic fluid, the air, by proper contrivances, can be intimately mixed with it, and made to act on every part of it, external and internal, at the ſame time. This great power of flame, which is the conſequence of this, does not appear when we try ſmall quantities of it, and allow it to burn quietly, becauſe the air is not intimately mixed with it, but acts only on the outſide, and the quantity of burning matter in the ſurface of a ſmall flame is too ſmall to produce much effect.

But when flame is produced in large quantity, and is properly mixed and agitated with air, its power to heat bodies is immenſely increaſed. It is therefore peculiarly proper for heating large quantities of matter to a violent degree, eſpecially if the contact of ſolid fuel with ſuch matter is inconvenient. Flaming fuel is uſed for this reaſon in many operations performed on large quantities of metal, or metallic minerals, in the making of glaſs, and in the baking or

burning of all kinds of earthen ware. The potter's kiln is a cylindrical cavity, filled from the bottom to the top with columns of wares, the only interſtices are thoſe that are left between the columns; and the flame, when produced in ſufficient quantity, proves a torrent of liquid fire, conſtantly flowing up through the whole of the interſtices, and heats the whole pile in an equal manner.

Flaming fuel is alſo proper in many works or manufactories, in which much fuel is conſumed, as in breweries, diſtilleries, and the like. In ſuch works, it is evidently worth while to contrive the furnaces ſo that heat may be obtained from the volatile parts of the fuel, as well as from the fixed; for when this is done, leſs fuel ſerves the purpoſe than would otherwiſe be neceſſary. But this is little attended to, or ill underſtood in many of thoſe manufactories. It is not uncommon to ſee vaſt clouds of black ſmoke and vapour coming out of their vents. This happens in conſequence of their throwing too large a quantity of crude fuel into the furnace at once. The heat is not ſufficient to inflame it quickly, and the conſequence is a great loſs of heat. See LABORATORY.

It is a known truth, that fuel cannot conſume by means of heat alone, without the admiſſion of freſh air, and this is no way more clearly proved, than by this eaſy experiment. Let a ſtrong cylinder of iron, hollow within, be fitted with a firm ſcrew at each end; in the cavity of this cylinder encloſe a long piece of charcoal, an then ſcrew up both the ends faſt, and place the whole in a ſtrong fire; let it continue there for ſeveral hours; and when it is taken out and cooled, open it, and the piece of charcoal will be found ſtill black, in its own form, and no way apparently altered or diminiſhed.

It is plain from this, that the conſumption of fuel depends upon the rarefaction, diſlodgment, briſk agitation, and diſcharge of its inflammable vapour, by means of freſh air; and hence we have the reaſon of the known rule of extinguiſhing fires by ſmothering them.

It is provided by ſtatute, that wood fuel ſhall not be felled under the aſſize. See BILLET and FAGGOTS.

FUEN, in *Geography*, a river of China, which runs into the Hoang, in the province of Chan-ſi. N. lat. 35° 29'. E. long. 110° 14'.

FUENARABIA, or FUENTERABIA. See FONTARABIA.

FUENCALIENTE, a town of Spain, in Old Caſtile, near the ſource of the Xalon; 15 miles N. of Siguença.

FUEN-HOA-FOU, a city of China, in the province of Pe-tcheli, celebrated for its extent and the number of its inhabitants, as well as for the beauty of its ſtreets and triumphal arches. It is ſituated near the great wall, amidſt mountains, and has under its juriſdiction, beſides two cities of the ſecond, and eight of the third claſs, a great number of fortreſſes which bar the entrance of China againſt the Tartars. Among the animals of the adjacent territory, the moſt remarkable are yellow rats; which are much larger than thoſe ſeen in Europe, and whoſe ſkins are much valued by the Chineſe. The contiguous mountains afford cryſtal, marble, and porphyry.

FUENSALIDA, a town of Spain, in New Caſtile; 18 miles N.N.W. of Toledo.

FUEN-SI, a town of China, of the third rank, in the province of Chan-ſi; 12 miles W.N.W. of Teho.

FUEN-TCHEOU-FOU, an ancient and commercial city of China, in the province of Chan-ſi, ſituated on the river Fuen-ho; its baths and ſprings, almoſt as hot as boiling water, attract a great number of ſtrangers, who contribute greatly to its opulence. To its diſtrict belong one city of the ſecond, and ſeven of the third claſs. N. lat. 37° 20'. E. long. 111° 26'.

FUENTE, LA, a town of Spain, in Aſturia; 20 miles S.W. of Santillana.

FUENTE *Duenna*, a town of Spain, in New Caſtile, ſituated on the Tagus; 24 miles S.E. of Madrid.

FUENTE-*Ginaldo*, a town of Spain, in Eſtremadura, uſed by the Spaniards in the ſucceſſion-war as a depôt for corn and cattle; 16 miles N.W. of Coria.

FUENTE *de Nanſa*, a town of Spain, in Aſturia; 28 miles S.W. of Santander.

FUENTE-*el-Olmo*, a town of Spain, in Old Caſtile, between Segovia and Aranda de Duero.

FUENTE *Ovejuna*, a town of Spain, in the province of Cordova; 32 miles N.W. of Cordova.

FUENTE *de la Piedra*, a village of Spain, in the province of Grenada, having a medicinal ſpring, of virtues known to the ancients, and celebrated for curing various diſorders, particularly the gravel; 6 miles from Antequera.

FUENTE *de la Reyna*, a town of Spain, in Valencia; 15 miles N. of Segorbe.

FUENTE *del Sabuco*, or *de Saburro*, a town of Spain, in the kingdom of Leon; 16 miles from Salamanca.

FUENTELSOL, a town of Spain, having a Carthuſian monaſtery, in Aragon, ſeated on the Ebro; 20 miles S.S.E. of Saragoſſa.

FUENTES, FORT, a fort of Switzerland, founded by the count de Fuentes, governor of Milan, in 1603, completed in 1606, and called by his name. It is ſeated upon an inſulated rock, about 1½ mile from the neareſt ridge of mountains, and two miles from lake Como, ſo that it completely commands the only great opening which leads into the Valteline, either from the Milaneſe or the Griſons; and of courſe it was a ſituation of great importance, when the poſſeſſion of the Valteline was an object of conſequence to the houſe of Auſtria. The fortifications are a quarter of a mile in circumference, conſtructed with ſtone, and contain a few ruinous barracks for ſoldiers, and the governor's houſe, which is in a wretched condition. The plain below the rock is marſhy, and renders the fort extremely inſalubrious. The Spaniards were accuſtomed to ſtyle this place, from its peculiar ſituation, the *yoke* of the Griſons, while the Griſons, in alluſion to its bad air, termed it, with greater propriety, the *grave* of the Spaniards. The view from the fort is remarkably picturеſque, on one ſide the rich Valteline, watered by the turbulent Adda; on the other, the lakes of Como and Chiavenna, beautifully encircled with numerous towns and villages. The hills which ſkirt the Valteline and the lake of Como preſent a variegated landſcape of foreſts, cornfields, and paſtures, finely contraſted, towards the Griſons, by the Rhætian Alps covered with eternal ſnow.

FUENTES, a town of Spain, in the province of Leon; 13 miles N.W. of Placentia.

FUENTES *de Onoro*, a town of Spain, in the province of Leon; 13 miles W. of Cividad Rodrigo.

FUERTE *de St. Joſef*, a town of South America, in the province of Tucuman; 95 miles N.E. of St. Miguel de Tucuman.

FUERTE *de Valbena*, a town of South America, in the province of Tucuman, on the Salado; 60 miles E.N.E. of St. Miguel de Tucuman.

FUESSEN, or FUSSEN, a town of Germany, in the biſhopric of Augſburg, ſituated on the Leech, and a frontier town to Bavaria and the Tyroleſe, with a Benedictine abbey

abbey and convent of Franciſcans; 47 miles S. of Augſburg. N. lat. 47° 34'. E. long. 10° 43'.

FUESSLI, JOHN-GASPARD, in *Biography*, an ingenious artiſt and writer, was born at Zurich in 1706; but having ſtudied the principles of painting under his father, he went to Vienna about the year 1724, without any means of ſupport, and without recommendations to thoſe whoſe patronage might be beneficial to him. Here, however, he attracted the notice of the principal nobility, and meeting with encouragement, in every reſpect adequate to his wants, he reſided at Vienna, till, at the earneſt ſolicitation of prince Schwarzenberg, he was induced to go to Radſtadt, where he became a favourite of the margravine, who was anxious to convert him to the Catholic religion. From Radſtadt he went to Nuremberg, where he formed an intimate friendſhip with the celebrated Rupezki, under whom he ſtudied, with a view to improve himſelf in his profeſſion. He next viſited Augſburg and Munich, and returned to Swiſſerland, where he arrived in his thirty-fourth year, and ſoon after married. His talents now claimed the reſpect of the moſt eminent artiſts. By Mengs he was preſented with a MS. treatiſe "On the Beautiful," which he publiſhed with a preface. With Winkelman he lived in the cloſeſt habits of friendſhip, and being as zealouſly attached to the beauties of poetry as he was famous as a painter, he maintained a correſpondence with Kleiſt, Klopſtock, Wieland, Bodmer, and other great men of the age. In the years 1740 and 1742, he loſt two of his beſt friends Rupezki and Rugendas, and being deſirous that men ſo eminent, and for whom he felt ſo ſtrong an affection, ſhould not be forgotten by poſterity, he wrote a biographical account of them. This, his firſt attempt in the department of literature, meeting with a very favourable reception, he ſet about reſcuing from oblivion ſome of his meritorious countrymen, by publiſhing as complete a hiſtory as poſſible of the artiſts of Swiſſerland. In this work, which he completed with great labour, perſeverance, and patience, he ſhewed himſelf a good writer and a ſound critic in the arts. He died at Zurich in May 1782, leaving behind him a moſt reſpectable character. He had very long been regarded as worthy the eſteem and friendſhip of perſons of the higheſt rank and eminence. But though accuſtomed to live with the great, he diſdained the arts of adulation, and was free and open in his manners and behaviour. His houſe was the reſort for thoſe who cultivated and were attached to the arts. His circumſtances were always very moderate, yet he was not deficient in his ſupport of men of letters, and was ready to ſerve thoſe who ſtood in need of his help. "Negligent," ſays his biographer, "in regard to himſelf, he was careful of others; and, though incapable of knocking at the doors of the great on his own account, he was not aſhamed to collect money from them when he had it in his power to contribute towards the ſupport of any child of misfortune." Moreri.

FUFA, in *Geography*, a town of Japan, in the iſland of Niphon; 140 miles W.N.W. of Jeddo.

FUGA, one of the iſlands called Barbuaynes, about 22 miles in circumference. N. lat. 19°. E. long. 121° 27'.

FUGA *Demonum*, in *Botany*, a name uſed by ſome authors for the hypericum, or St. John's wort.

FUGA, Ital. from *fugere*, Latin, to fly, a movement in *Muſic*, in which the leading part or firſt treble is purſued by the ſecond, the ſecond treble by the tenor, and the tenor by the baſe; ſo that a *fugue* is a *flight* and a *purſuit*. This ſubject has been ſo amply treated in the article COUNTERPOINT, to which the reader is referred, that little remains to be added to it here, except to recapitulate its laws, and the doctrines of learned harmoniſts in ſupport of them. Rouſſeau defines a fugue "a piece of muſic in which a trait of melody, called the *ſubject*, is treated, according to certain eſtabliſhed rules of harmony and modulation in making it paſs ſucceſſively and alternately from one part to another." The ſubject reſembles the *text* of a ſermon, out of which all that is ſaid ſhould naturally ariſe, and ſerve as a commentary and illuſtration. But though, for variety, or to indulge caprice, fugues and canons have been compoſed in all intervals, yet orthodox contrapuntiſts allow no fugues to be regular, but thoſe of which the anſwer is made in the fifth, fourth, eighth, or uniſon, as then the intervals will be the ſame. And of the anſwers, the preference is given to the fifth, then to the fourth, eighth and uniſon; as the effect is pleaſing in that order. It muſt be remembered that the ſubject itſelf, as of all other movements, ſhould begin on the key note, its fifth or its eighth. Of the various rules by which a true anſwer to a fugue may be tried, Dr. Pepuſch adviſes *ſolmiſation*; Padre Martini the modes of the Romiſh church, called *authentic* and *plagal*; both good in the three hexachords and their minor relatives; but in tranſpoſed keys, in which ſeveral flats or ſharps occur at the clef, there is no rule more certain and unexceptionable than giving the anſwer in exactly the ſame intervals as the ſubject, only remembering that if one part riſes a fifth, the other will only riſe a fourth, as C ♯ — G ♯ — G ♯ — C ♯ — *et e contra*: as G — C ♯ — C ♯ — G ♯. See AUTHENTIC, and PLAGAL. But this is only in leading off. The reſt of the anſwer muſt be in the ſame intervals, and characters for time, as the ſubject, except in prolation, augmentation and diminution, which give the anſwer in longer or ſhorter notes than the theme. See PROLATION, AUGMENTATION, and DIMINUTION. All fugues and canons are *imitations*; but the term *imitation* is only applied to irregular fugues, when the intervals are not the ſame. The anſwer to a regular fugue may commence in the middle of the ſubject, which will unite them together, and make them reciprocally accompaniments to each other. It were impoſſible to enumerate all the ingenious contrivances that have been uſed in the works of great fughiſts. The following are the moſt frequent.

FUGA *per Arſin et Theſin*, or fugue in contrary motion.

FUGA *per Contrari Movimenti*.

FUGA *in Conſequenza*, is ſometimes uſed for canon.

FUGA *Omofona*, a fugue in uniſon.

FUGA *Libera*, free fugue. A canon is ſo called.

FUGA *Legata*, and a ſtrict fugue, a canon.

FUGA *Perpetua*, perpetual fugue.

FUGA *Vacui*, in *Ancient School Philoſophy*, a ſuppoſed averſion in nature to a vacuum.

Moſt of the phenomena which the ancients aſcribed to the fuga vacui, the moderns have demonſtrated to ariſe from the gravity and preſſure of the air. This is the caſe in the aſcent of water in ſyringes, pumps, &c.

FUGALIA, in *Antiquity*, a feaſt celebrated among the Romans, ſuppoſed by ſome to be the ſame with the regifugium, held on the 24th of February, in memory of the expulſion of the kings, and the aboliſhing of the monarchical government. Struvius, Antiq. Rom. Syntag. cap. 9. diſtinguiſhes the fugalia from the regifuge; and even doubts whether the regifugium were thus called on account of the expulſion of the kings, or becauſe the rex ſacrorum, after the ſacrifice was ended, fled haſtily out of the forum and comitia.

Be this as it will, the only ancient author of note that makes expreſs mention of the fugalia is St. Auguſtine, De Civitate Dei, lib. ii. cap. 6. And his commentator Vives ſhews a great inclination to correct the reading of the word,

word, were it not that St. Auguſtine adds, that the feaſt was a true fugalia, all decency and modeſty being baniſhed from it.

That learned perſon conjectures, that the fugalia were the ſame thing with the poplifugia, or the feaſt of Fugia, the goddeſs of joy, occaſioned by the rout of an enemy, which was the reaſon why the people abandoned themſelves to riot and debauchery; and that the feaſt was firſt inſtituted on occaſion of the victory gained over the Ficulnates, Fidenates, and neighbouring nations, upon their attempt to take poſſeſſion of Rome, the day after the people had withdrawn from it, as related by Varro, lib. v. de Ling. Lat.

But, according to Varro, the poplifugia which fell in the month of June, were held in memory of the flight or retreat of the people, in a ſedition raiſed among them: it is true, he adds, that the day followed ſoon after the retreat of the Gauls, and the time when the neighbouring nations conſpired againſt them: but this does not appear to have any relation to the poplifugia, being only meant to mark the era or time when the ſedition and flight of the Roman people happened. After all, though the poplifugia might have been originally eſtabliſhed in commemoration of the flight of the people, and not that of the enemies, this does not hinder, but the fugalia of St. Auguſtine may probably be the poplifugia of Varro, according to the conjecture of Vives.

FUGAM Fecit, in *Law*, a term uſed where it is found, by inquiſition, that a perſon fled for felony, &c. And if flight and felony be found on an indictment for felony, or before the coroner, where a murder is committed, the offender ſhall forfeit all his goods, and the iſſues of his lands, till he is acquitted or pardoned; and it is held that when one indicted of any capital crime, before juſtices of oyer, &c. is acquitted at his trial, but found to have fled, he ſhall, notwithſtanding his acquittal, forfeit his goods, but not the iſſues of his lands, becauſe by the acquittal the land is diſcharged, and conſequently the iſſues. 3 Inſt. 218. H. P. C. 27. 2 Hawk. P. C. 450. The party may, in all caſes, except that of the coroner's inqueſt, traverſe the finding of a fugam fecit; and the particulars of the goods found to be forfeited, may be always traverſed; alſo whenever the indictment againſt a man is inſufficient, the finding of a fugam fecit will not hurt him. 2 Hawk. 451. Making default in appearance on indictment, &c. whereby outlawry is awarded, is a flight in law.

FUGAS, in *Geography*, a river of Africa, which runs into the Indian ſea, near Jubo, on the coaſt of Zanguebar.

FUGHE, Ital. the plural of *fuga*, fugues. See Double Counterpoint.

During the rage for fugues, air, accent, grace, and expreſſion were equally unknown to the compoſer, performer, and the hearer; and whatever notes of one voice or inſtrument were in tune with another, were welcome to the player, provided he found himſelf honoured from time to time with a ſhare of the ſubject, or principal melody; which happening more frequently in canons, and fugues, than in any other ſpecies of compoſition, contributed to keep them ſo long in favour with performers of limited powers, however tireſome they may have been to the hearers, when conſtructed on dull and barren themes. It has been ſaid by M. Marpurg (Traité de la Fugue), that fugues enjoy the privilege of greater longevity than any other ſpecies of muſic. A good fugue is an evergreen, and never grows old-faſhioned; but then it muſt be conſtructed on a pleaſing and fertile ſubject, and carried on with ſpirit; and a fugue on a dull and dry ſubject, however correct the compoſition, is a monotonous and tireſome compoſition.

The greateſt fughiſts, in practice on the organ, during the laſt century, were, doubtleſs, Sebaſtian Bach and Handel; but the moſt learned theoriſts and writers on the ſubject of fugue, whoſe treatiſes we have conſulted and doctrines adopted, are Dr. Pepuſch, Padre Martini, and the late Sig. Nicolo Sala. From the publications of theſe reſpectable authors, we have given in the muſic plates, ſubjects and fragments of fugues in 2, 3, and 4 parts, to ſhew enquirers into the art what are regarded as true anſwers to regular fugues. But we inform the young ſtudent, that even great fughiſts, beſtowing no thought on *melody*, beſides their inattention to *phraſeology*, are equally indifferent about *accent*; ſo intent is their ſearch after harmony and contrivance, that if the accents of the anſwers are ever the ſame as in the ſubject, it is more by accident than deſign. But if the accents of the anſwers differ from thoſe of the theme, the imitation is imperfect, and the whole compoſition becomes confuſed and unintelligible.

FUGI'LE. The ceruminous ſecretion of the ear; alſo an appearance in the urine like wax. The term has likewiſe two different ſurgical ſignifications; ſometimes it means a bubo; ſometimes, a ſwelling of the parotid gland.

FUGITIVA, La, in *Geography*, a ſmall iſland in the Pacific ocean, diſcovered by Quiros in the year 1606. S. lat. 14° 20′. W. long. 151° 50′.

FUGITIVE, *Refugee*, a perſon obliged to fly his country, or remove from a place where he had ſome abode or eſtabliſhment, on account of his crimes, debts, or on other occaſions.

In the Roman law, a fugitive ſlave was ſuch a one as was apt to run away from his maſter. And in ſelling a ſlave, the maſter was obliged to declare, whether or not he were fugitive.

The term is alſo applied to deſerters in an army, or thoſe who fly from the combat.

Fugitives' *Goods*, *bona fugitivorum*, the proper goods of him that flies upon felony, which, after the flight lawfully found on record, do belong to the king, or lord of the manor. 5 Rep. 109.

Fugitives *over Sea*, are perſons that go over ſea without the king's licence, who, unleſs they are merchants, or eminent perſons, or king's ſoldiers, forfeit their goods; and maſters of ſhips, &c. carrying ſuch perſons beyond ſea, ſhall forfeit their veſſels; and alſo, if the ſearcher of any port ſhall negligently ſuffer any perſons to paſs, he ſhall be impriſoned, &c. Stat. 9 Edw. III. cap. 10. and 5 Ric. II. cap. 2. Theſe ancient ſtatutes are obſolete, if not expired.

Fugitive *Pieces*, among the learned, denote thoſe little compoſitions which are printed on looſe ſheets, or half ſheets; thus called, becauſe eaſily loſt, and ſoon forgot.

FUGLOE. See Fogloe.

Fugue. See Fuga.

There are three kinds of fugues; the *ſingle fugue*, *double fugue*, and *counter-fugue*.

Fugue, *ſingle* or *ſimple*, is ſome point conſiſting of 4, 5, 6, or any other number of notes, begun by one ſingle part, and then ſeconded by a third, fourth, fifth, and ſixth part, if the compoſition conſiſts of ſo many, repeating the ſame, or ſuch like notes; ſo that the ſeveral parts follow, or come in, one after another, in the ſame manner, the leading parts ſtill flying before thoſe which follow.

Fugue, *double*, is when two or more different points move together in a fugue, and are alternately interchanged by ſeveral parts.

For

For the *Counter-fugue*, ſee COUNTER-*fugue*.

The Italians ſay, a *fugue*, or *flight of rooms*, or *chambers*, meaning a ſeries, or range of rooms, the doors whereof anſwer in a right line behind each other, ſo as they may be all ſeen at once, from one extreme to the other.

FUHME, in *Geography*, a river of Germany, which runs into the Mulda, 2 miles S. of Ragune, in the electorate of Saxony.

FUH-SANAH, a town of Africa, in the country of Tunis; 110 miles W.S.W. of Tunis.

FUHSE, a river of Germany, which runs into the Allier, near Zell.

FUIRENA, in *Botany*, ſo named by Rottböll in memory of George Fuiren, a Daniſh botaniſt. Rottb. Gram. 70. Linn. Suppl. 11. Nov. Gram. Gen. 25. Schreb. 40. Willd. Sp. Pl. v. 1. 255. Juſſ. 26. Lamarck, t. 39. Claſs and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoideæ*, Juſſ.

Gen. Ch. *Cal.* Spike round, imbricated on all ſides, with wedge-ſhaped, channelled, three-keeled ſcales, each tipped with a ſhort ſtraight awn. *Cor.* Glumes three, rather membranous, inverſely heart-ſhaped, flat, entire, with an incurved terminal awn. *Stam.* Filaments three, linear, inſerted into the receptacle within the baſe of each glume of the corolla; anthers linear, erect. *Piſt.* Germen ſuperior, large, triangular; ſtyle thread-ſhaped; ſtigmas two, revolute. *Peric.* none, except the withered corolla. *Seed* one, naked, triangular, deſtitute of down.

Eſſ. Ch. Spike imbricated, with abrupt awned ſcales. Corolla of three obcordate awned valves. Seed ſolitary, triangular, beardleſs.

1. F. *umbellata*. Rottb. Gram. 70. t. 19. f. 3. (F. paniculata; Linn. Suppl. 105.) Native of Surinam. *Stem* two or three feet high, ſimple, angular, ſtriated. *Leaves* ſheathing, broadiſh, ribbed, acute, glaucous; their ſheaths hairy. *Flower-ſtalks* axillary and terminal, bearing ſeveral ſeſſile umbels of ſoft blueiſh ſpikes, half an inch long. This is the only ſpecies, and is not known, except in a dried ſtate, to European botaniſts. Its habit is that of a *Cyperus* or *Scirpus*, but the glaucous hue is remarkable.

FULBERT, in *Biography*, a learned French prelate, who flouriſhed at the latter end of the tenth and in the commencement of the eleventh centuries, was an Italian by birth. He was a diſciple of Gerbert, who aſcended the pontifical throne in 999, under the name of Sylveſter II. From Rome he came to France, and delivered public lectures. Here his ſcholars were very numerous, who, imbibing the inſtructions of their maſter, diffuſed his learning and various information over France and Germany, and the other northern ſtates of Europe, ſo that Fulbert is juſtly regarded as one of the principal reſtorers of learning and of the ſciences in that age. Some hiſtorians aſſert that he was chancellor of France, but others contend that his chancellorſhip extended only to the church of Chartres. In 1007 he was appointed to the vacant ſee of Chartres, and governed the church with great prudence upwards of twenty years. In conjunction with this biſhopric he held the treaſurerſhip of St. Hilary at Poictiers, but he expended the profits of the ſituation in rebuilding his cathedral church. Fulbert was highly eſteemed by Robert, king of France, by Canute, and Richard II. of England; by the dukes of Normandy and Aquitaine, and by other eminent princes and great men of his time. He was author of many theological pieces, but the moſt valuable extant is a collection of "Letters" by himſelf and friends, to the number of 134. He died in the year 1028. All his works were collected and publiſhed in a ſeparate form at Paris in 1608: they are alſo inſerted in the 17th vol. of the Bibliotheca Patrum. Fulbert was a friend to literature and ſcience, but not in the beſt ſenſe of the term; for he was an enemy to freedom of enquiry, and a furious zealot againſt thoſe who ventured to diſſent from any of the doctrines of the eſtabliſhed church. Moreri.

FULCIMENT, in *Natural Hiſtory*, is a term for the plant-like bodies, formed by zoophytic animals, as habitations or ſupports, and which, according to their conſiſtence, are denominated *coral*, *coralline*, or *ſponge*, &c. The application of this term to the ſcientific diſcrimination and arrangement of organic foſſils, or *reliquia* of this kind, will be found in Martin's "Outlines of the Knowledge of extraneous Foſſils," p. 88. 97. and 103. See RELIQUIA.

FULCRA, in *Botany* and *Vegetable Phyſiology*, the Props, or rather Appendages, of the herbage of many plants. We prefer this latter term in Engliſh, becauſe though the word *fulcrum* means a prop or ſupport, it is, in that ſenſe, not applicable to more than one kind of the organs in queſtion, the tendril. See CIRRUS.

Theſe appendages are of ſeven kinds.

1. *Stipula*. The Stipula or Stipulas. Theſe are an appendage to the proper leaves or to their footſtalks, commonly ſituated at the baſe of the latter, in pairs, as in the Roſe, the Pea family, and others. In the Coffee, *Gardenia*, and others of the Rubiaceous family, as well as in the common genus *Polygonum*, they are intrafoliaceous and ſimple, embracing the ſtem within (or above) the leaf-ſtalks. In theſe caſes the Stipulas are permanent; in the Tulip-tree, *Liriodendron*, they are in pairs, and fall off as the leaves unfold. In graſſes the ſimple ſtipula crowns the inſide of the ſheath of their leaf. This is idly termed *ligula* by ſome, for it is a real *ſtipula*.

2. *Bractea*. The Floral Leaf. This is a leafy appendage proper to the flower or its ſtalk, various in form and duration, ſometimes coloured, as in the Purple or Pink-topped Clary, *Salvia Horminum*.

3. *Spina*. A Thorn. Proceeds from the wood itſelf, being a modification of the materials of a bud, and is found in *Hippophae*, *Rhamnus*, and various ſpecies of *Cratægus* or *Meſpilus*. It is liable to diſappear by culture.

4. *Aculeus*. A Prickle. Ariſes from the bark only, and is ſtripped off with it, having no connection with the wood. Examples are found in the Roſe, Bramble, and Gooſeberry. The prickle does not diſappear in conſequence of culture like the *Spina*.

5. *Cirrus*. A tendril or claſper, by which moſt climbing plants are ſupported upon others. To this the word prop is therefore juſtly applied. See CIRRUS.

6. *Glandula*. A gland, or little tumour diſcharging a fluid, as in the viſcid clothing of the calyx and ſtalk of a Roſe, eſpecially the Moſs-roſe, and many ſimilar inſtances. The liquor diſcharged is either reſinous, and often aromatic, or ſweet and viſcid like honey.

7. *Pilus*. A Hair, including the various rough, hairy, or downy clothing of plants. This in the nettle conſiſts of an excretory duct, diſcharging a venomous fluid through each hair or briſtle, and the ſame holds good in divers plants whoſe hairy coats exude a clammy moiſture, to all which the Linnæan idea of a *pilus* is ſuitable, that it is "an excretory duct, of a briſtle-like form," differing therefore in ſhape only from the *glandula*. But in the greater number of caſes the hairs are merely a protection againſt cold, heat, or animals. They are often hooked, forked, branched, or entangled. Very generally they are curiouſly jointed and tubular; ſometimes they are flat, like minute ſhavings; ſometimes,

sometimes, as in Viper's Bugloſs, they are bulbous or tuberous at the baſe, and as hard as a ſhell in that part. The hairs of many of the Mallow family, and ſome ſpecies of *Croton* and *Solanum*, are beautifully and curiouſly ſtellated, and compoſe ſometimes a ſoft, ſometimes a very harſh coat to the whole of the leaves, ſtalks, and calyx.—The pubeſcence of plants varies greatly in degree according to circumſtances, but its direction is found to be very conſtant, affording good ſpecific characters in *Mentha*, *Myoſotis*, and *Fragaria*. In the latter the poſition or direction of the hairs ſeems to be aſcertained with more certainty after the plants are dried, which may account for its having been generally overlooked. See FRAGARIA.

FULCRUM, PROP, in *Mechanics*. See LEVER and HYPOMOCHLION.

FULDA, CHARLES-FREDERIC, in *Biography*, was born at Wimpfen, in Swabia, and educated at the gymnaſium of Stuttgard, near Tubingen. In the year 1748 he was appointed chaplain to a regiment in Holland. When this was diſbanded, which happened in a few months, he made a tour through various parts of Germany, and in 1749, completed his ſtudies at Gottingen. His firſt literary production was a prize diſſertation on the principal dialects of the German language, which was crowned by the Royal Society of Gottingen, and the facts and reaſonings of which he introduced, ſome years after, in his "Dictionary of the German Roots." After this he publiſhed another work, entitled an "Enquiry into Language." He did not confine his reſearches to language alone, but extended them to hiſtory and antiquities in general. Of this he gave various proofs in his many publications; but his principal work, and which is regarded as a treaſure of hiſtorical knowledge, ingenuity, and inventive genius, is his Chart of Hiſtory, publiſhed at Augſburg in 1783. In early life he was accuſtomed to render different objects of knowledge eaſier to be retained in the memory by graphic repreſentations; and when he was farther advanced he exhibited, in a ſort of genealogical tree, the connection of all the ſciences, profeſſions, arts, and handicrafts. He repreſented, in a ſimilar manner, in 1787, all the organs of ſpeech, with the origin of human language. Fulda died at Einzigen, in December 1788. Though he devoted his intellectual endowments to the cultivation of language, and the inveſtigation of its principles and philoſophy, yet he was converſant with all the ſciences; and was an excellent practical mechanic; made his own houſehold furniture; alſo implements for weaving; and worked them himſelf with great ſucceſs. Gen. Biog.

FULDA, in *Geography*, a biſhopric and principality of Germany, in the circle of the Upper Rhine, bounded on the N. by Heſſe-Caſſel, on the E. by the county of Henneberg, on the S. by the biſhopric of Wurzburg, and on the W. by the principality of Iſenburg and Heſſe; about 40 miles in length, and from 7 to 25 in breadth. The country is mountainous and woody, with ſome rich arable lands, and ſome ſalt and medicinal ſprings. From being a cloiſter of Benedictine monks, erected in 744, this biſhopric was formed in 1752 by pope Benedict XIV. In 1802 this biſhopric was given to the prince of Naſſau Dillenberg, late Stadtholder, as an indemnity for this office, and his dominions in Holland.

FULDA, a city of Germany, and capital of the above-mentioned biſhopric, ſituated on the river Fulda. It was made a town in the year 1162; and became the reſidence of the biſhop. Beſides the cathedral, it has a collegiate church, an univerſity founded in the year 1734, a college, an academy, and a convent of Benedictines. It is ſituated nearly in the centre of the dioceſe; the chapter of which is compoſed of thirteen canons. The library contains a number of ancient and rare manuſcripts. It is diſtant 63 miles E.N.E. from Mentz. N. lat. 50° 33′ 57″. E. long. 9° 43′ 45″.

FULDA, a river of Germany, in the circle of Upper Rhine, which paſſes by the town of Fulda, and joining the Werra at Minden, their confluence forms the Weſer.

FULFULÆ, in *Ancient Geography*, a town of Italy, in the country of the Samnites.

FULGENIA, or FULGENEVA, FOLIGNI, or FOLIGNO, in *Geography*, a town of Italy, in Ombria.

FULGENTIUS, in *Biography*, an African prelate in the ſixth century, was a deſcendant from an illuſtrious family of Carthage, but born at Lepte, in the province of Byzacena, about the year 468. He was early introduced to the ancient languages, and made ſo much progreſs, that while he was a boy he could repeat the whole of Homer, and even converſe in the Greek language with purity and fluency. At a proper age he was recommended to a poſt under government, which, however, not being agreeable to his mind, he relinquiſhed, in order that he might retire from the world and embrace a religious life. Fulgentius entered a monaſtery under the diſcipline of Fauſtus, and when this community was diſperſed by perſecution, he entered into another, where the high opinion entertained of his ſanctity and zeal occaſioned his being appointed colleague with Felix, the ſuperior of that inſtitution. The Moors, in a ſhort time, ſcattered in all directions the religious of this monaſtery, and Felix and Fulgentius were ſubjected to much cruel perſecution and perſonal ſufferings. Fulgentius afterwards embarked for Egypt, but having touched at Syracuſe he was perſuaded to abandon the idea of proceeding on his voyage. He went to Rome in the year 500, and having offered his devotions at the pretended ſepulchres of the apoſtles, returned to Africa, where he eſtabliſhed a new monaſtery; but his attachment to a ſolitary way of life led him to deſire a greater degree of privacy, and he reſolved to withdraw to a ſecluded ſpot among the Venetian Iſlands. His ſuperiors, however, inſiſted upon employing his talents in the catholic cauſe, and compelled him to return to his monaſtery, under the penalty of incurring excommunication. He was now ordained preſbyter, and in 504, or as others affirm in 508, he was conſecrated biſhop of Ruſpa. After this he was baniſhed in common with the other catholic biſhops of Africa to the iſland of Sardinia: here, though a junior among his brethren, he was called upon, from the known ſuperiority of his talents, to exerciſe his pen in the vindication of themſelves and their depreſſed cauſe. In the year 522 Fulgentius, and his fellow-ſufferers, were recalled and met with a joyful reception from the orthodox in Africa. Fulgentius appears to have ſpent the remainder of his life in tranquillity, diſcharging the duties of his epiſcopate with great diligence and prudence, and rendering himſelf highly uſeful by his piety and exemplary manners. He was frequently appointed to preſide at the ſynods which were held by his party. He died in the year 533, leaving behind him numerous treatiſes in theological controverſy. Fulgentius has been praiſed for the correctneſs and clearneſs of his creed, his intimate knowledge of the ſacred ſcriptures, his eloquence in addreſs, and his ſubtlety in argumentation. He has been called the Auguſtine of his age, becauſe he not only conformed to the tenets held and juſtified by that father, but imitated his ſtyle. He had many good qualities, but theſe were debaſed by the ſuperſtitious notions of religion and devotion that he had early imbibed: and by the credit of his character and influence, the ſpirit of monkery was widely diſſeminated among the chriſtians in Africa.

FULGO, in *Geography*, a river of Hindooſtan, which runs into the Mahany; 10 miles N.N.W. of Bahar.

FULGORA, in *Entomology*, a genus of hemiptera in the Linneæan ſyſtem, *Ryngota* of Fabricius, and *Orthoptera* of Lamarck, and later French writers.

This genus is characteriſed by having the head hollow, inflated, and extended forward; the antennæ ſhort, ſeated beneath the eyes, and conſiſting of two joints, the outer one larger and globular; beak elongated, inflected, and containing four joints; and the legs formed for leaping.

The fulgora ſeem to have entirely eſcaped the attention of European naturaliſts till within the ſpace of the laſt century, when an intereſting account, accompanied with figures, of the ſpecies lanternaria appeared in the coſtly volumes of Madame Merian's "Inſectorum Surinamenſium;" and about the ſame period the deſcription of another example of the ſpecies was given by Dr. Grew of London, in his work entitled "Muſeum Regalis Societatis." The hiſtory of this inſect, as related by Merian, is indeed ſurpriſing, and was much diſcredited in the firſt inſtance, notwithſtanding that the account given by that lady was in part corroborated by the teſtimony of Dr. Grew, and ſo far as reſpected the luminous property of that extraordinary creature, her veracity is completely confirmed by his authority. The paſſage to which we chiefly allude is to the following effect: "Once" ſays Madame Merian "when the Indians brought me a number of theſe lantern carriers, I put them into a wooden box, without being aware of their ſhining at night; but one night being awakened by an unuſual noiſe, and much frightened, I jumped out of bed and ordered a light, not knowing whence the noiſe proceeded. We ſoon perceived that it originated in the box, which we opened with ſome inquietude, but were ſtill more alarmed, after opening it and letting it fall on the ground, for a flame appeared to iſſue from it which ſeemed to receive additional luſtre, as often as another flew out of it. When we obſerved this ſome time, we recovered from our terror, and admired the ſplendour of theſe little animals." "Diſſert. de Generatione et Metamorphibus, &c." Theſe remarks are ſanctioned by Grew, when he obſerves that the circumſtance "which beſide the figure of the head is moſt wonderful in this inſect (Cucujus Peruvianus) is the ſhining property of the ſame part, whereby it looks at night like a lantern, ſo that two or three of theſe faſtened to a ſtick, or otherwiſe conveniently diſpoſed of, will give ſufficient light to thoſe who walk or travel in the night."

Relations ſimilar to the above are given by the miſſionaries who traverſed South America; nor does the fact appear to be conteſted except by Renard, who, in contradiction to thoſe writers, aſſures us that this extraordinary inſect does not emit light. That Madame Merian has committed a ſerious though perhaps hitherto undetected error in delineating this fulgora as the offſpring of the great cicada of Surinam, is very evident, and the commiſſion of this alone ſhould incline us to be cautious in repoſing implicit reliance on her obſervations; but as to the actual exiſtence of phoſphoric light in this individual ſpecies of fulgora, as recorded in her publication, we cannot reaſonably entertain the ſlighteſt doubt. It is even poſſible that obſerver of nature may be correct, and Renard alſo, ſince, like the lampyrides, the inſect may poſſeſs the power to diſplay or withdraw its luminous appearance at pleaſure, or this appearance may be aſſumed only at particular ſeaſons, and in that caſe probably at the period of their amours. Whether however the light emitted by this ſpecies of fulgora be permanent or not, it is ſufficiently evident on the teſtimony of thoſe who have witneſſed its ſhining properties, that the light produced is remarkably powerful and clear. Pere du Tertre declares in his "Hiſtoire des Antilles" that he could diſtinctly read his prayers by the light of one of them; and Leſſer, in his "Theologie des Inſectes," affirms that the Indians keep them in their houſes, and require no other light in the night time; an inſect of this ſort being ſufficient ſo far to illuminate an apartment of moderate ſize, as to enable its inhabitants to perform whatever houſhold work may be neceſſary.

The fulgora lanternaria was the only ſpecimen of this ſingular tribe of inſects known, till about the middle of the eighteenth century, when that curious and very abundant kind the Chineſe lantern-carrier (F. Candelaria) was brought to Europe. An account of this inſect was given by Roeſel, who at the ſame time obſerves, that he had never ſeen or heard of it in the works of any author. The tranſactions of the Stockholm academy include however the earlieſt figure and deſcription of this ſpecies, and it was from this ſource Linnæus introduced it into his Syſtema Naturæ. At firſt Linnæus referred it with the great lantern-carrier to the coleopterous order, under the appellation of lanternariæ; in a ſubſequent edition they are incorporated with his cicadæ, and laſtly they were allowed to conſtitute a diſtinct genus under the name which they retain at preſent.

The details afforded in the works of the above-mentioned writers, reſpecting the luminous properties of theſe inſects, awakened conſiderable attention among naturaliſts, as we learn from Degeer, Seba, Reaumur, and others; and ſome progreſs was alſo made in the aſcertainment of other ſpecies of the ſame tribe, eſpecially by the firſt of thoſe authors, notwithſtanding which, however, it is only within the laſt twenty or thirty years that we have become acquainted with the greater number of the ſpecies which compoſe the genus at this time. It does not appear that more than ten ſpecies were known to Linnæus, and thoſe including all that were deſcribed by Degeer, Seba, and others of his predeceſſors, but the total amount of thoſe inſerted in the works of Fabricius, Drury, Stoll, Donovan, and others, have increaſed that number to about thirty ſpecies.

The light diſſeminated by the luminous kinds of fulgora, (for it does not appear that all the ſpecies inherit this property) is generally imagined to iſſue from the trunk, or elongated projection of the forehead, but Roeſel offers a conjecture on that emitted by the fulgora lanternaria, which on further inveſtigation may enable naturaliſts to determine whether the light be entirely produced by an innate property of the trunk, or whether the inſect does not receive at leaſt an additional degree of ſplendour from ſome external cauſe. He notices a white farinaceous ſubſtance beſprinkled over various parts of the wings and body, as well as the trunk, which he obſerves looks like wood in that ſtate of decay when it aſſumes a ſhining aſpect in the dark. The ſame idea has occurred to us: we have frequently, if not invariably, found a ſimilar white powder on other inſects of this genus, which are known to be of the luminous kinds; and it is therefore poſſible, in our opinion, that its preſence may tend to increaſe, though it does not abſolutely excite, that vivid glow of light which theſe inſects unqueſtionably exhibit.

Reaumur endeavoured to diſcover the origin of this phoſphoric appearance in the fulgora lanternaria, and found, on diſſecting the trunk, that it was completely empty, which is indeed the truth in all the ſpecies of this tribe we have examined. But the obſervation advanced by Reaumur, as a late French author (Latreille) has well remarked, proves nothing, becauſe it is very likely that in the living inſect this cavity is filled with fluid matter, which dries or evapo-

rates with the other juices of its body after the inſect dies, and therefore, that until an opportunity be afforded to ſome intelligent naturaliſt to inſpect the trunk of the living inſect, we muſt remain in uncertainty whether that organ be excluſively the ſeat of that animated phoſphoric matter which renders the creature luminous, or whether, as before remarked, the farinaceous dots may not contribute, in a greater or leſs degree, to increaſe the ſplendour of its appearance. For a more ample diſcuſſion of this intereſting ſubject the reader may be referred to the remarks on the fulgora candelaria, in Donovan's "Inſects of China," and thoſe of fulgora pyrrorhynchus, feſtiva, and hyalinata, in the "Inſects of India," by the ſame author.

Species.

LANTERNARIA. Front extended, ſtraight; wing-caſes variegated; wings with a large ocellated ſpot on each. Linn.

A ſpecies far exceeding the reſt in magnitude, its length being from three to four inches, and the expanſion, when the wings and wing-caſes are extended, about ſeven inches. The trunk is remarkably large in proportion to the ſize of the inſect, and of a yellowiſh brown colour ſimilar to that of the wing-caſes; the wings in general rather paler. The whole ſurface is prettily variegated with dots of brown and black, and on the trunk in particular are a few conſpicuous ſpots of bright red on each ſide. When in fine condition, the wings, wing-caſes, and body, both above and beneath, are moſt elegantly dotted with ſpecks of fine white powder, but which is of a texture ſo extremely delicate as to rub off with almoſt the ſlighteſt touch of the finger. This is the powder before mentioned, and which is ſuppoſed to poſſeſs the property of emitting a phoſphoric light. It is a native of South America.

CANDELARIA. Front extended, aſcending; wing-caſes green, ſpotted with yellow; wings yellow, with black tips. Linn.

Der kleinere Aſiatiſche oder Chineſiſche lanternen-trager, Roeſ. *De gewapende cicade*, Stoll. *Chineſe lantern carrier*, Donov. Inſ. China.

This inſect is found in great abundance in ſome of the Chineſe provinces, and is occaſionally brought, with other inſects, common in that empire, to the European factories for ſale as an object of curioſity. It is a ſpecies of elegant appearance, and when in fine preſervation is obſerved to be beſprinkled with a kind of farinaceous ſubſtance on the wings and body, ſimilar to that on the fulgora lanternaria, though in a very inconſiderable degree.

SERRATA. Front roſtrated, aſcending, and armed with four ſeries of ſerrations. Seba, &c.

This extremely curious and uncommon ſpecies of fulgora is a native of Surinam; and is in ſize the ſame as that of the Chineſe lantern-fly; in form it alſo nearly correſponds, but the four diſtinct ſeries of ſharp teeth with which the extended ſnout is furniſhed, independently of its diſſimilarity in colour, at once remove this inſect, not only from the Chineſe ſpecies, but from every other of the fulgora tribe. The wing-caſes are brown, and the wings reddiſh, with an elegant ocellated ſpot near the tip. The only example of this intereſting inſect we are acquainted with is in the cabinet of A. Macleay, Eſq.

DIADEMA. Front extended, muricated, and trifid at the tip; wings black with red margin. Linn. *Fulgora armata*, Drury.

A rare ſpecies found in India.

PYRRORHYNCHUS. Trunk aſcending; apex red; wing-caſes brown with a pale band acroſs the middle; wings black, at the baſe green. Donov. Inſ. India.

Deſcribed from an unique ſpecimen brought many years ago from the interior of Hindooſtan by governor Holford. Its general outline is not unlike that of the Chineſe lantern-fly, fulgora candelaria, which latter however it materially exceeds in ſize. The colours are remarkably vivid in this inſect, yet nothing is more worthy of mention than the peculiar beauty of its trunk, the organ through which the "living light" is diffuſed; this is of a very rich and deep purple, from the baſe upwards to the apex, and the apex itſelf of a fine ſcarlet, and ſomewhat pellucid. The nocturnal appearance of this extraordinary creature, when on the wing, is conceived to be infinitely more ſingular than that of any known ſpecies of fulgora, the lampyrides, or other luminous inſects yet diſcovered, as the illuminated apex muſt naturally reſemble a globule of fire, or heated iron, and the numberleſs phoſphoric dots, relieved by the purple colour of the tube, appear like a train of glittering ſtars behind it.

The only figure of a fulgora in any reſpect reſembling this ſpecies is given in the work of Stohl, under the title of "De Groote Goene Coromandeliſche Lantaarndrager" (green lantern-carrier fly of Coromandel). The general aſpect of theſe latter inſects accords with the preſent ſpecies, except in the ſtructure of the trunk, which is altogether different, being recurved, tapering gradually from the baſe to an acute point at the apex, and of an olive black colour. The following account of this inſect is given by Stohl "In De Nederlandſche Kabinetten," &c. "This inſect was not known in the cabinets of the Low Countries till within the laſt three years (A.D. 1780.) during which time a few were brought from Tranquebar, on the Coromandel coaſt, to the cabinet of natural curioſities of his royal highneſs the Stadtholder of the United Provinces, of which I have been obligingly permitted to take the figure of a female, by Monſ. Voſmar, to whom I owe my public acknowledgments for it." The rarity of the above deſcribed inſects will afford a ſufficient apology for the introduction of theſe little anecdotes concerning them.

PHOSPHOREA. Front ſubulate, extended, and aſcending; body grey glaucous. Linn. *Cicada filiroſtris*, Degeer.

Native of Surinam.

NOCTIVIDA. Front roſtrated, pointed, and aſcending; body green; wings hyaline. Linn. *Cicada coniroſtris*, Degeer.

Inhabits ſame country as the preceding.

LUCERNA. Front roſtrated and prominent; body above greeniſh, beneath yellow. Linn. *Cicada breviroſtris*, Degeer.

A South American ſpecies.

FLAMMEA. Front roſtrated, aſcending, roundiſh, and truncated. Linn.

Native of South America.

TENEBROSA. Front roſtrated, ſtraight, and truncated; wing-caſes ſcabrous and grey. Fabr. *Cicada lanternaria fuſca*, &c. Degeer.

The head of this inſect is fuſcous, with the front rufous; thorax and wing-caſes rough with raiſed dots; and the wings duſky. Inhabits Guinea.

OBSCURATA. Front roſtrated, ſtraight, and truncated; wing-caſes cinereous with black ſpots. Fabr. Donov. Inſ. New Holland.

An inſect of ſmall ſize, deſcribed by Fabricius, from the Bankſian cabinet: the ſpecies inhabits New Holland; its ſnout is the length of the body, of a black colour with the baſe white, and marked with white dots, and two white bands;

bands; the thorax is brown; wings white, and legs black and white varied.

ADSCENDENS. Front extended, aſcending, and ſubulate; wing-caſes ferruginous brown, dotted with white. Fabr.

A native of Cayenne, deſcribed by Fabricius, from the cabinet of Rohr. The ſize of this inſect is ſmall; the ſnout above black, beneath yellow; head beneath yellow with two oblique black ſtreaks, and a black dorſal line above; wings hyaline; body yellow, and border of the abdomen black on the back.

FASCIATA. Frontr oſtrated and aſcending; wing-caſes ferruginous brown, with two green bands, and a dot of green behind. Fabr.

Inhabits ſame country as the laſt, and is about the ſame ſize; the head is conic and grooved, yellow with the back brown; thorax brown; body yellow; and abdomen rufous above.

TRUNCATA. Front ſomewhat obtuſe; wings green and truncated. Linn.

Native of India.

PLANA. Front extended, flat, and yellowiſh; thorax and wing-caſes ferruginous. Fabr.

A ſmall ſpecies found in Cayenne; the head is grooved beneath; anterior edge of the thorax yellow; wing-caſes hyaline at the tip; body yellow; abdomen above ferruginous.

HYALINATA. Front conic, and unequal; wing-caſes hyaline, with a black ſtreak. Fabr. Donov. Inſ. India.

This curious inſect, and which till very lately was conſidered extremely rare, is found according to Mr. Fichtel (who brought a number of them to Europe) in very conſiderable abundance in the vicinity of Bengal. Its ſize is moderate; the front conic, unequal above, and grooved beneath; the colour pale, inclining to browniſh, with ſtreaks and ſpecks of black. The eyes are large, white, and globular; thorax pale ſpeckled with black; the wings hyaline, with a black ſpot at the tip.

PALLIPES. Front extended and flat; wing-caſes green, with hyaline tips. Fabr.

Size of fulgora plana; the head black, with a whitiſh margin extending entirely round; the thorax greeniſh, with a black blotch on the fore part; wing-caſes rather yellowiſh at the baſe, with a ſtreak of black ſpots at the tip; beneath yellow; wings hyaline.

FOLIUM. Front extended, ſhort, and ſtraight: body yellow-green; wings very large, vertical and compreſſed. Degeer.

Native of America.

FESTIVA. Front conic; wing-caſes brown, the outer margin greeniſh, with black and fulvous dots; wings red at the baſe. Fabr. Donov. Inſ. India.

Inhabits Coromandel. The head is flat above and of a brown colour, beneath yellowiſh edged with black; thorax brown; wings ſanguineous red with the tips brown.

EUROPÆA. Front conic; body green; wings hyaline and reticulated. Linn.

Native of France and Germany, and has been once diſcovered in England. Vide Donov. Britiſh Inſects. The ſize is ſmall, ſcarcely exceeding that of the carrion or fleſh fly; the colour throughout a delicate pea-green; the wings and wing-caſes hyaline, with the nerves of the ſame green colour as the body.

FENESTRATA. Front conic, and furrowed; wing-caſes hyaline, with a marginal fuſcous ſpot. Fabr.

An African ſpecies deſcribed from the Bankſian cabinet; it is rather leſs than the laſt; the front yellowiſh; wings without ſpots.

MINUTA. Front conic; head and thorax yellowiſh; dorſal line and wing-caſes whitiſh. Fabr.

A ſmall ſpecies found in Saxony; the antennæ are ſhort and thick; body entirely yellowiſh, with a white dorſal line on the head and thorax, and the wing-caſes pale.

LIMBATA. Fuſcous with hyaline wing-caſes, marked with two brown ſpots on the diſk, and many on the borders; the nerves punctured. Fabr.

Size of the laſt, and alſo inhabits Saxony; the antennæ are ſhort, thick, and ſetaceous at the tip; wing-caſes longer than the body; wings hyaline and immaculate.

PELLUCIDA. Brown; wing-caſes white, hyaline, and immaculate. Fabr.

Native of Saxony. The body entirely brown, and the legs teſtaceous. Size of the former.

FLAVESCENS. Yellowiſh; wing-caſes hyaline and without ſpots. Fabr.

The antennæ of this ſpecies are ſhort, thick, and cetaceous at the end; the head and thorax yellowiſh without ſpots; body yellowiſh. This inhabits Saxony, and is of the ſame ſize as the preceding.

STRIATA. Yellowiſh; head black and ſtriated; wing-caſes yellowiſh, hyaline, and immaculate. Fabr.

Reſembles the foregoing in ſize, and alſo inhabits Saxony. The head is black ſtriated with yellow; thorax yellowiſh, and the abdomen beneath black at the baſe.

MARGINATA. Black; head ſtreaked with yellowiſh; anterior edge of the thorax with the legs yellowiſh; wing-caſes hyaline. Fabr.

This correſponds in ſize with the former; the antennæ are duſky and thick, and the head black with three yellowiſh ſtreaks; the body black, and the legs yellowiſh. A native of Saxony.

Fabricius, who deſcribes the five laſt mentioned inſects, from examples in the cabinet of Hybner, ſuggeſts at the ſame time, that though he admits them among the fulgora, it is poſſible they ought rather to conſtitute a new genus, ſince they not only differ in their general habit from the true fulgora, but alſo in the ſtructure of their antennæ, which latter objection is certainly materially worthy of conſideration in the eſtabliſhment of an eſſential character. We may perhaps beſides add, with ſome propriety, in ſpeaking of this genus generally, as adopted both by Linnæus and Fabricius, that ſome advantage would ariſe to the entomologiſt, were thoſe ſpecies of the fulgora which have the trunk conſiderably elongated, to be removed from thoſe which have the front very ſlightly advanced, or projected at leaſt in ſuch an inconſpicuous degree as rather to approach the cicada than fulgora tribe. The latter we conceive might conſtitute a diſtinct genus.

FULGOSIO, RAPHAEL, in *Biography*, generally ſuppoſed to be a native of Placentia, was profeſſor of the law in the college there, and likewiſe at Pavia. He afterwards occupied the profeſſor's chair at Padua, where he had a large ſalary. For his great knowledge in juriſprudence he was ſent to the council of Conſtance, and was of great uſe to that aſſembly by his dexterity and profound knowledge. He was often delegated on public buſineſs to Venice. He died in 1427, and a very ſplendid monument was erected to his memory in the church of St. Anthony at Padua. He was author of many learned works, as Commentaries upon the Code and Digeſt, Councils, &c. Moreri.

FULGURATING PHOSPHORUS, a term uſed by ſome Engliſh writers to expreſs a ſubſtance of the phoſphorous kind, the preparation of which does not ſeem to have been well known to any but the inventor of it. It

was prepared both in a liquid and a dry form, and not only ſhone in the dark in both ſtates, but communicated its light to the things it was rubbed on. If incloſed in a glaſs veſſel well ſtopped, it ſometimes would fulgurate, or throw out little flaſhes of light, and ſometimes fill the whole vial with waves of flame. It does not need recruiting its light at the fire, or in the ſunſhine, like the phoſphorus of the Bolonian ſtone, but of itſelf continues in a ſtate of ſhining for ſeveral years together, and is ſeen as ſoon as expoſed in the dark; the ſolid or dry matter always reſembling a burning coal of fire, though not conſuming itſelf. Phil. Tranſ. N° 134. See PHOSPHORUS.

FULHAM, in *Geography*, a village of England, in the county of Middleſex, ſeated on the Thames, over which is a bridge, which is ſubject to a toll for foot paſſengers, as well as cattle and carriages. In 1801 the number of inhabitants were 4428. The biſhop of London has a palace here; 4 miles W. of London.

FULICA, in *Ornithology*, a genus of the grallæ, with the bill convex, the upper mandible arched over the lower at the edge, and the lower gibbous near the tip; noſtrils oblong; front bald, and feet four-toed and pinnate. The genus is divided into two families, gallinule and coot; the firſt of which have the feet cleft, the other pinnate; this is the arrangement adopted by Linnæus. Some writers conſider theſe families as generically diſtinct, allowing only thoſe with pinnated feet to remain in the genus fulica, and conſtituting the others as a genus under the name of gallinule. The latter appears to be the moſt correct diſtribution of theſe birds according to their natural character, as they not only differ in the ſtructure of their feet, but in other eſſential particulars. The gallinules have the upper mandible membranaceous at the baſe, and the wings concave: the coots have the mandibles equal, and the noſtrils oval, narrow, and ſhort. Both tribes frequent watery places, and feed on worms, inſects, and ſmall fiſh.

Species.

FUSCA. Front and bracelets yellowiſh; body browniſh. Gmel. *Fulica albiventris*, Scop. *Gallinula minor*, Briſſ. *Rallus Italorum*, Geſner. *Poulette d'eau*, Buff. *Brown Gallinule.*

This bird inhabits France, the neighbourhood of Venice, and other ſouthern parts of Europe. Its haunts are the ſame as that of the common gallinule, but though it frequents the ſame places, it never aſſociates with that ſpecies, its diſpoſition being ſhy and ſolitary. The fleſh is in eſteem.

The length of this bird is about 12 inches. There is another analogous kind, and which is commonly conſidered as a variety, ſuperior to this in ſize, the length being 18 inches. The latter is the gallinula major of Briſſon; the body is cheſnut above, beneath cinereous, with the feathers edged with white; head and neck blackiſh, and the lower part of the belly white.

CHLOROPUS. Front tawny; bracelets red; body blackiſh. Scop. *Gallinula chloropus major*, Aldrovandus. *Poule d'eau*, Buff. *Common water-hen, or moor-hen*, Ray. *Common gallinule*, Lath. Donov. Britiſh Birds, &c.

The moor-hen is a native of America as well as Europe, and is about fourteen inches in length. Though from the ſhortneſs of the wings it flies with difficulty, it runs with great facility, and ſwims well. It frequents the borders of ponds, and rivers that are ſheltered with weeds, and builds near the water ſide upon low trees or ſhrubs; the neſt is compoſed of herbage, and contains about ſeven eggs, which are of a yellowiſh white colour, marked with irregular brown reddiſh ſpots. Theſe birds lay twice or thrice in the ſeaſon.

The bill of this bird is red with the tip greeniſh; the irides red; body above ſooty black mixed with olive, beneath cinereous; the outer edge of the wings and lower tail-coverts white, and legs greeniſh.

VIRIDIS. Above greeniſh, beneath white; front, bill, and legs greeniſh yellow. Gmel. *Porphyrio viridis*, Briſſ. *Poule ſultane verte*, Buff. *Green gallinule*, Lath.

A native of the Eaſt Indies. The length of this kind is eleven inches and a half; the bill of a greeniſh yellow; body above dull green, beneath white; the legs greyiſh yellow, with grey claws.

MELANOCEPHALA. Blue; head and neck black. Gmel. *Porphyrio melanocephalos*, Briſſ. *La Poule ſultane à tête noir*, ibid. *Black-headed gallinule*, Lath.

Entirely blue, except the head and neck, which are black, and a broad bare ſpace on the crown. In the female the crown and body above is tawny, the ſhoulders ſtreaked with white; wings greeniſh tinged with tawny, and the quill-feathers greeniſh blue. Native of America.

PURPUREA. Purple; bill pale; legs greeniſh yellow. Gmel. *Acintli*, Buff. *Quachilto*, Ray. *Crowing gallinule*, Lath.

Inhabits the marſhes of New Spain, and crows like a cock; the fleſh is good; called by the natives of Mexico yacacintli.

FLAVIROSTRIS. Above azure; throat blueiſh-white; belly and rump white; wings and tail brown; bill and legs yellow. Gmel. *La favorite de Cayenne*, Buff. *Favourite gallinule*, Lath.

Length 12 inches. Inhabits Cayenne.

PORPHYRIO. Front red; bracelets many; body green, beneath violet. Gmel. *Poule ſultane, et taleve de Madagaſcar*, Buff. *Purple water-hen*, Albin. *Purple gallinule*, Lath.

The bill and legs are red, irides tawny; head and neck above gloſſy violet; cheeks and throat violet-blue; back and rump gloſſy green; wings and rounded tail ſhining green; within brown. Size of a fowl, the bill and legs ſtout, the former compreſſed at the baſe. The female ſmaller than the male. This ſpecies inhabits in a greater or leſs abundance all the warmer parts of the globe; the female forms its neſt in reeds in marſhy places; lays three or four eggs, and ſits from three to four weeks. They are eaſily tamed, and domeſticated with the common poultry, and feed on fiſh, roots, fruits, ſeeds, and other ſimilar ſubſtances, and occaſionally, it is ſaid, like the parrot, will ſtand on one leg and lift the food to the mouth with the other. The fleſh is exquiſite.

VIOLACEA. Black violet; neck beneath blue; front and legs red. Lath. *Violet gallinule.*

Found with the laſt. The vent is white.

CARTHAGENA. Front blue; body rufous. Gmel. *Carthagena gallinule.*

Deſcribed by Jacquin as a native of Carthage in America. Size of the large black coot.

CAYANENSIS. Grey-brown; breaſt and upper part of the belly rufous, back and wings olive; chin whitiſh. Lath. *Grand poule d'eau de Cayenne*, Buff. *Cayenne gallinule.*

Very common in ſome parts of South America, where it frequents marſhy places, and feeds on fiſh and inſects. The bill is duſky at the tip; legs red, back tinged with olive. The length is eighteen inches.

RUFICOLLIS. Crown, neck above, with the back and quill-feathers brown; chin white; throat and breaſt rufous; belly,

belly, vent, and rump black. Gmel. *Black-bellied gallinule*, Lath.

The length of this bird is ſeventeen inches, the bill two inches and a half, red at the baſe, and at the tip yellow. The quill-feathers are rufous at the margin; flanks and lower wing-coverts faſciated with rufous and black. The legs long and red. Native place uncertain, but ſuppoſed to be Cayenne.

MADERASPATANA. Front and temples white; body above cinereous, beneath white. Gmel. *Porphyris maderaſpatanis*, Briſſ. *Angoli*. Buff. *Madras rail-hen*, Ray. *Madras gallinule*, Lath.

Inhabits the coaſt of Coromandel and Malabar, where it is known by the names of Boollu-cory, and Caunangoly. Its ſize is that of the common duck. The throat is marked with ſemi-circles; the quill-feathers cinereous, edged with black, and the bill and legs very long.

MARTINICENSIS. Front and bracelets blue; body violet. Jacquin. *Porphyrio minor*, Briſſ. *Petite poule-ſultane* Buff. *Martinico gallinule*.

Leſs than the common gallinule, being in length only twelve inches; the bill rather exceeds an inch, and is of a yellow colour, with the baſe red; the eyes are black; legs yellow; back and upper part of the wings greeniſh-brown; tail blackiſh above, beneath white. Inhabits the Weſt India iſlands.

NOVÆBORACENSIS. Legs brown; crown, and neck above olive ſpotted with white; back brown; breaſt dirty yellow. Gmel. *Yellow-breaſted gallinule*. Arct. Zool.

Size of a quail. The ſpecies inhabits New York.

NÆVIA. Bill and legs greeniſh; front ſaffron; feathers of the head and upper parts of the body black edged with rufous; margin of the dorſal feathers white; eye-brows white; wings and tail brown. Gmel. *Porphyrio nævius*. Briſſ. *Grinette*, Buff. *Small water-hen*. Albin. *Grinette gallinule*, Lath.

Length nine inches and three-quarters; the irides yellowiſh-green: chin, throat, and breaſt blueiſh-aſh ſpotted with black; tail-feathers on the outer edge, and two middle ones on both edges, white. Inhabits Italy.

MACULATA. Above reddiſh-brown; front and bill yellow; temples and throat white; wings ſpotted black and white; breaſt, belly and tail brown; two middle tail-feathers black tipt with white. Gmel. *Porphyrio punctulatus*, Briſſ. *Matkneltzel*, *Matkern*, Ray. *Speckled gallinule*.

Inhabits marſhes in Germany; its length is eleven inches; the bill of a dull yellow colour, and the legs grey.

FLAVIPES. Front and legs yellowiſh; head, body above, and tail rufous, ſpotted with black; beneath white; wings black. Gmel. *Porphyrio rufus*, Briſſ. *Gallinula ochropus major*, Ray. *Smirring*, Buff. *Yellow-legged gallinule*, Lath.

Native of Germany. The bill is yellow with black tip; margin of the eye-lids ſaffron; temples white; greater wing-coverts next the body white. Size of the common moor-hen.

FISTULANS. Front yellowiſh-green; body above brown. Beneath white, wings and tail brown. Gmel. *Porphyrio fuſcus*, Briſſ. *Glout*, Buff. *Piping gallinule*, Lath.

Inhabits borders of rivers in Germany, and feeds chiefly on ſmall fiſhes, worms, and inſects.

CINEREA. Cinereous, middle of the belly white. Gmel. *Creſted gallinule*. Lath.

Deſcribed from a ſpecimen in the Britiſh Muſeum, which is ſuppoſed to have been brought from China. The length is eighteen inches. Forehead and crown bare, of a reddiſh colour, and riſing into a knob at the back part, in a manner not unlike the caruncle on the head of the pintado; the chin is ſtriped with white; the back and wings greeniſh-aſh, the latter pale on the outer margin.

The above-mentioned ſpecies are of the gallinule, and the following of the coot tribe.

ATRA. Front fleſh-colour; bracelets greeniſh-yellow; body blackiſh. Scopoli. *Fulica*, Bellon. *Phalaris*, Geſner. *Foulque ou Morelle*, Buff. *Common coot*, Lath. Donov. Brit. Birds, &c.

A general inhabitant of Europe, Aſia, and America; frequents marſhy places, and forms a floating neſt among the ruſhes; the eggs are numerous, of a dirty-white colour, ſprinkled with minute ſpots of deep ferruginous. The young ſwim and dive with amazing facility almoſt as ſoon as hatched. Theſe birds feed on ſmall fiſhes, aquatic inſects and ſeeds, and in the winter ſeaſon are often found near the ſea. The bill is yellowiſh-white, and the front white, except in the pairing ſeaſon, when it becomes red; the legs are greeniſh-yellow, and the outer edge of the wings white.

ATERRIMA. Front white, bracelets red; body blackiſh. Gmel. *Fulica major*, Briſſ. *Grande foulque ou macroule*, Buff. *Blaeſſling*, Günther. *Greater coot*.

Differs from the laſt in being larger, and is perhaps not ſpecifically diſtinct from that kind. Found in Europe and Siberia.

AMERICANA. Cinereous; front, chin, and line in the middle of the belly white; legs blue-black. Gmel. *Cinereous coot*.

Larger than the common coot, and inhabits South America.

AETHIOPS. Entirely black. Sparrman Muſ. Carlſ.

Native place uncertain.

MEXICANA. Purple; front and bill red; back, wings and rump greeniſh. Gmel. *Yohoalcoachillin*, Ray. *Mexican coot*.

Inhabits New Spain, and is larger than the common coot. The bill is yellow at the tip; back, rump and wing-coverts varied with blue and tawny.

CRISTATA. Blue-black; naked front and crown red; caruncle red, bifid, and erect. Gmel. *Grande foulque à crête*, Buff. *Creſted coot*.

Length eighteen inches; bill whitiſh, with the baſe red, and legs duſky; bracelets of three colours, red, green, and yellow. The ſpecies inhabits Madagaſcar and China.

FULIGINOUS, an epithet applied to a thick ſmoke, or vapour, replete with ſoot or other craſs matter. See SMOKE.

The word is formed from the Latin *fuligo*, ſoot, and is rarely uſed but when joined with vapour

In the firſt fuſion of lead, there exhales a great deal of fuliginous vapour, which retained and collected, makes what we call *Litharge*; which ſee.

Lamp-black is what is gathered from the fuliginous vapours of pines, and other reſinous woods, when burnt. See *Lamp-*BLACK.

FULIGO METALLORUM, a term uſed by the chemiſts, ſometimes to expreſs arſenic, and ſometimes crude mercury.

FULIGULA, in *Ornithology*, a name given by Geſner to a ſpecies of duck, ſeeming to be the ſame with a kind common on the Yorkſhire ſhores; the *anas marila* of Linnæus. See DUCK. The ſame author alſo deſcribes another ſpecies under the name of *anas fuligula prima*, which ſeems the ſame with the *capo negro*, or *tufted duck*. See DUCK.

FULKE, WILLIAM, in *Biography*, was born in London about the middle of the ſixteenth century. In 1555 he was ſent to St. John's college Cambridge. From this univerſity he entered himſelf a ſtudent at Clifford's Inn London, and applied moſt diligently to the ſtudy of the law: but he had a ſecret deſire of quitting legal enquiries for theological inveſtigation, and returned to his college to purſue that courſe of ſtudy that ſhould ultimately fit him for the church.

His father, diſpleaſed at the change, refuſed to contribute to his ſupport. By the help of friends he contrived to maintain himſelf till he was choſen fellow of his college in the year 1564, and diſtinguiſhed himſelf by his proficiency in the different branches of learning, particularly in mathematics and theology. In the following year, when he was M. A. of three years ſtanding, he was incorporated in the ſame degree in the univerſity of Oxford. Having formed an intimate acquaintance wi.h the learned Thomas Cartwright, who was attached to the ſentiments of the puritans, Mr. Fulke embraced the ſame opinions, and is deſcribed by Anthony Wood, as jointly with Dr. Humphrey "ſtandard bearers, for a long time of the non-conformiſts, who did grow conformable in the end, as they grew riper in experience and ſager in judgment." By the public avowal of his ſentiments, he rendered himſelf ſo obnoxious, that he was expelled his college, and obliged to maintain himſelf by delivering lectures in his private apartments. After this he was patronized by the earl of Leiceſter who preſented him to the living of Warley in Eſſex, and afterwards to that of Didington in Suſſex; he then took his degree of doctor in divinity at Cambridge by mandamus, and went to France in the capacity of chaplain to the Engliſh embaſſy. Upon his return he was appointed maſter of Pembroke hall, and lady Margaret's profeſſor. He died in 1589: as a young man he ſuſtained the character of a good philoſopher, and in more advanced life, that of a pious and ſolid divine. He was author of numerous treatiſes, chiefly controverſial, but the moſt important of his works is a "Comment upon the Rheims Teſtament," firſt publiſhed in 1580, and reprinted in 1617, with the title of "the Text of the New Teſtament of Jeſus Chriſt, tranſlated out of the vulgar Latin by the papiſts, &c. with arguments of books, chapters, and annotations, pretending to diſcover the corruption of divers tranſlations: whereunto is added the tranſlation out of the original Greek, commonly uſed in the church of England, with a confutation of all ſuch arguments," &c. He was author likewiſe of "A Defence of the ſincere and true Tranſlation of the Holy Scriptures into the Engliſh Tongue againſt the cavils of Gregorio." Martin. Gen. Biog.

FULL is variouſly uſed, in oppoſition to empty, narrow, confined, &c.

The Carteſians hold, that the univerſe is full, *i. e.* that every part or point has matter in it.

An ambaſſador has full power given him to act, tranſact, &c. The army was in full march, *i. e.* the whole army was in march, with all the forces it conſiſted of.

A man is ſaid to bear the arms of a family full, *i. e.* without any difference or diminution.

FULL *Age.* See AGE, in *Law.*

FULL *Arms.* See ARMS.

FULL *Forfeiture.* See FORFEITURE.

FULL *Moon, plenilunium,* that phaſis of the moon, when her whole diſk or face is illuminated; which is in the time of her oppoſition to the ſun.

Eclipſes of the moon always happen at or near the time of full-moon. See ECLIPSE.

FULL *and by,* a *Sea-phraſe,* denoting a ſituation of a ſhip with regard to the wind, when ſhe is cloſe-hauled, and ſailing in ſuch a manner, as neither to ſteer too nigh the direction of the wind, nor to deviate to leeward, both of which movements are unfavourable to her courſe: as in the former her ſails will ſhiver, and render the effort of the wind precarious and ineffectual; and in the latter ſhe will advance in a direction widely diſtant from her real courſe. Hence, "keep her full" is the order from the pilot or other officer, to the helmſman, not to incline too much to windward, and thereby ſhake the ſails ſo as to retard the courſe. Falconer.

FULLER, a workman employed in the manufactories, to full, mill, or ſcour cloths, rateens, ſerges, and other woollen ſtuffs, by means of a mill, to render them thicker, and more compact and durable.

The word is formed of the Latin *fullo,* which ſignifies the ſame thing.

The fullers amongthe Romans waſhed, ſcoured, and fitted up cloaths; and their office was judged of that importance, that there were formal laws preſcribed them for the manner of performing it. Such was the Lex Metalla de Fullonibus. See alſo Pliny, lib. vii. cap. 56. Ulpian, leg. 12. ff. de Furtis, lib. xiii. § 6. Locati, lib. xii. § 6 ff. &c. See FULLING.

FULLER, NICHOLAS, in *Biography,* a learned Engliſh divine, was born at Southampton in the year 1557, where he received his education. After this he was taken into the family of Dr. Horne biſhop of Wincheſter, and had an ample opportunity of purſuing his ſtudies, till at length he was made ſecretary to that prelate. Upon the death of biſhop Horne, he was choſen to the ſame office under Dr. Watſon his ſucceſſor, but in the courſe of a few months he determined to retire, in order that he might devote himſelf to literary purſuits, more congenial to his temper than a life of active buſineſs. Before his plans were well arranged, he was invited to become the tutor to the ſons of a gentleman in Hampſhire, two of whom he accompanied to the univerſity of Oxford in the year 1584, and matriculated, at the ſame time with them, as a member of St. John's college. Having ſpent ſome time in this learned ſeminary, and having taken both his degrees in arts, he was admitted to orders, and preſented with a ſmall living in Wiltſhire; and though its income was very inadequate to his comfortable maintenance, yet he felt contented, as it afforded him leiſure to apply himſelf to his literary and critical ſtudies. His ſkill in the learned languages, and his publications tending to illuſtrate the ſcriptures, gave him conſiderable celebrity, but it was not till late in life that he obtained any ſubſtantial reward for his various merits. He was at an advanced age made prebendary of Saliſbury, and preferred to the rectory of Biſhop's Waltham in Hampſhire, which he did not long enjoy. He died in 1622-3, at the age of ſixty-five years. His works are the "Miſcellanea Theologica," and a defence of the ſame againſt Druſius, who had charged him with plagiariſm. The "Miſcellanea," are inſerted in the ninth volume of the "Critici Sacri," and they may be found diſperſed in Pool's "Synopſis Criticorum." He was author of "An Expoſition of Rabbi Mordecai Nathan's Hebrew Roots with Notes;" and a "Lexicon," which remain in M. S. in the Bodleian library.

FULLER, *Nicholas,* contemporary of the preceding, was a barriſter, who boldly reſiſted the oppreſſion of archbiſhop Bancroft, and his brethren of the high-commiſſion court, againſt a miniſter and a merchant of the town of Yarmouth, who were impriſoned for being preſent at a conventicle, as it was denominated. He obtained a writ to bring them to the bar, when he moved for their liberation upon the principle that the high commiſſioners were not impowered by law to impriſon any of his majeſty's ſubjects. His pleas were ineffectual for his clients, and at the advice of Bancroft, who affected to regard Fuller as the champion of the non-conformiſts, this vindicator of the rights of the ſubject, was himſelf ſhut up in cloſe confinement, and there kept till the day of his death.

FULLER, *Thomas,* ſon of an eminent clergyman, was born at Aldwinkle in Northamptonſhire, in 1608. He made, under the inſtructions of the father, ſo rapid a progreſs, that at twelve years of age he was deemed fitted for the

ſtudies of an univerſity. He was accordingly ſent to Queen's college, where he applied himſelf with ſo much ardour and ſucceſs that he took his degrees with great applauſe in the years 1624 and 1628. He removed from Queen's to Sidney college, and was choſen miniſter of St. Bennet's pariſh, in the town of Cambridge. In 1631, he obtained a fellowſhip in Sidney college, and was almoſt at the ſame time collated to a prebend in the cathedral church of Saliſbury. Soon after this he was ordained prieſt, and preſented to the rectory of Broad Windſor in Dorſetſhire. In the year 1641, the nation being threatened by a civil war, Mr. Fuller, for the ſake of greater ſecurity, and in the expectation of better opportunities for his ſtudies, and a more ready acceſs to books, removed to London, where he acquired high reputation as a popular preacher, and was choſen lecturer of the Savoy in the Strand. Mr. Fuller was a member of the convocation, but diſapproved and reſiſted ſome of its meaſures which he thought to be of very dangerous conſequence. He was, nevertheleſs, zealouſly attached to the king, and by his open avowal in defence of the royal party, he was brought into danger with the parliament, who, in the end, deprived him of all means of ſubſiſtence, and of a church to preach in. He now engaged as chaplain to ſir Ralph Hopton, the duties of which office he conſtantly exerciſed as the army moved from place to place, omitting, however, no opportunity, as occaſions might occur, of purſuing his favourite ſtudies, and of making hiſtorical collections for his work, well known by the title of the "Worthies of England." Mr. Fuller, in ſeveral inſtances, was uſeful in animating the troops in defence of the cauſe for which they were contending. In the year 1643, he was appointed chaplain to the infant princeſs Henrietta Maria, who reſided at Exeter, and here he remained till that city ſurrendered in 1646, to the parliament forces, when he was permitted, without any reſtrictions, to remove to London. He was now choſen lecturer at Clement's Lane, in Lombard Street, whence he ſoon removed to St. Bride's church, Fleet Street. Some offence being taken, he was for a ſhort time ſuſpended from the functions of a preacher, but in 1648, he was allowed to proceed in his duty, and was preſented to the living of Waltham Abbey, Eſſex. Mr. Fuller ſpent that, and the following year, between the metropolis and Waltham, employing engravers to embelliſh with maps and other copper plate engravings his view of the Holy Land, entitled, "A Piſgah ſight of Paleſtine, and the Confines thereof, with the Hiſtory of the Old and New Teſtament acted thereon." This was publiſhed in folio in the year 1650, and in the following year he laid before the public a collection of lives, ſome written by himſelf, and ſome by others, of religious reformers, martyrs, &c. under the title of "Abel Redivivus." In 1656, he publiſhed his "Church Hiſtory of Britain from the Birth of Chriſt to the year 1648:" "The Hiſtory of the Univerſity of Cambridge ſince the Conqueſt;" and "The Hiſtory of Waltham Abbey." About the year 1659 or 1660, Mr. Fuller was invited to another living in Eſſex, where he exerciſed his miniſterial labours till he was appointed chaplain to lord Berkeley, who preſented him with the living of Cranford, in Middleſex. He afterwards went with his lordſhip to the Hague, to congratulate Charles II. on his reſtoration. He was now appointed chaplain to his majeſty, created doctor of divinity at Cambridge, and was in a fair road to a biſhopric, but taking a journey to Saliſbury, on the buſineſs of his prebend, he was attacked with a fever which put an end to his life in the year 1661. The laſt literary work on which his attention was employed was his "Hiſtory of the Worthies of England," part of which was printed during his life, and the reſt from his papers after his death. It was publiſhed in 1662, in folio. Beſides the works already mentioned, he was author of many others of which we may notice "David's hainous ſin, heærtie Repentance, and heævie Puniſhment," in 8vo., and a "Hiſtory of the Holy War," which laſt went through ſeveral editions. He printed likewiſe a ſermon which was preached at Weſtminſter abbey on occaſion of the king's commencing hoſtilities againſt his parliament, from the words "Yea let them take all, ſo that my Lord the King return in Peace." The funeral of this worthy man was performed by the direction and at the expence of lord Berkeley, and it was attended by two hundred of the clergy. Mr. Fuller had a very remarkable memory; he could repeat five hundred ſtrange and unconnected words after twice hearing them; and a ſermon, verbatim, after he had heard it once; he undertook, after paſſing from Temple Bar to the fartheſt part of Cheapſide and back again, to mention all the ſigns then over the ſhops, as they ſtood in order, on both ſides of the ſtreets repeating them backwards and forwards, and performed the taſk with great exactneſs. He had a great vein of wit, which is thought to have injured his writings; they nevertheleſs are repoſitories of much valuable and uſeful information. Biog. Brit.

FULLERS' *Earth*, in *Mineralogy*, *Argilla Smectis*, Waller; *Talcum fullonum*, Wern.; *Talcum Smectis*, Linn.; *Fullonia communis*, Forſt.; *Argille Smectite*, Haüy; *Terre à foulon*, Fr.; *Walker-Erde*, Germ.; *Walk-lera*, Swed.; a ſpecies of earth, which from the predominance of ſilex as a conſtituent part, (at leaſt in the varieties analyzed by Bergmann and Klaproth,) ſhould be referred to the ſiliceous genus, though Werner, guided by what he terms the characteriſtic component part, places it in the firſt diviſion of his talc genus, together with bole, native talc earth, and écume de mèr. Emmerling places it in his flint genus, in the ſame manner as all the varieties of common clay are transferred by him to that genus. It is fruitleſs to enter on any diſcuſſion with regard to the place a foſſil is to occupy in a ſyſtem, before all its relations, orycto-gnoſtical, chemical, and geological, are thoroughly underſtood; and this is more than at preſent can be ſaid of fullers' earth, which, in common with other mineral ſubſtances, denominated from the particular uſes to which they may be applied, is, both by collectors and writers, continually confounded with other ſubſtances, eſpecially with varieties of common clay. Hence it is that we find ſo very contradictory deſcriptions of the characters of this earth. The following external characters are principally derived from the varieties found in England, in Saxony, (particularly at Roſſwein, at the foot of the Saxon Ertzgebirge) in Auſtria, Moravia, the Palatinate, Alſace, and Sileſia. Many of thoſe from other parts of Europe that we have had an opportunity of ſeeing in collections, appeared to partake too much of the nature of common clay, others of that of ſteatite, while others again exhibited characters belonging to varieties of marle.

Fullers' earth is generally of a greeniſh colour, more or leſs mixed with brown and grey, together with a portion of yellow, by which various ſhades of dirty olive green are produced; ſometimes the yellow predominates, and a yellowiſh grey appears, paſſing over (in the genuine *Lemnian earth*, which, as we ſhall ſhew hereafter, cannot be ſeparated from fullers' earth,) into whitiſh grey. It is alſo found of various ſhades of red: that of Sileſia is tile red, ſometimes ſprinkled with white and green ſpots. Often ſeveral of the juſt mentioned colours are intimately; but mechanically, mixed; which, in ſome, can be obſerved only with the aſſiſtance of a magnifying glaſs. The brown colour, both uniform and in ſpots, is generally owing to an accidental admixture of iron ochre.

It

It has been found maſſive only, ſometimes conſtituting whole fletz-ſtrata. Large maſſes, on being ſeparated, generally diſunite into ſmaller pieces, when expoſed to the influence of the atmoſphere.

Internally it is more or leſs dull; its fracture being earthy, generally of a fine grain: often it appears perfectly conchoidal, and even ſlaty; but commonly the fragments are indeterminately angular and blunt-edged, and in the latter caſe perfectly opaque: in the pureſt varieties the edges are ſometimes tranſlucent. When ſcratched with the nail of the finger, or cut with a knife, it becomes ſmooth and ſhining.

It is very ſoft, almoſt friable, and mild; feels more or leſs greaſy, and ſcarcely adheres to the tongue. It does not ſoil. Specific gravity about 2.

Genuine fullers' earth does not effervеſce with nitrous acid; nor are all varieties of it inſtantly reduced into powder by that acid. But ſmall pieces put into water almoſt inſtantly crumble into conical heaps of minute, very ſoft particles, without producing a crackling noiſe, as is the caſe with bole; neither does a foaming take place, as has been copied by moſt authors from Cronſtedt, who attributes this quality to a fullers' earth found at Oſmund in Dalarne.

Though fuſible *per ſe*, it requires a high degree of heat: that of Hampſhire, according to Klaproth, melted in the charcoal crucible into a denſe, dark-grey, opaque ſlag, which had loſt 0.25 of its original weight, and contained many grains of iron. In the clay crucible the ſame was reduced to a cloſe, blackiſh, green ſlag, with ſoft, reddiſh, punctated ſurface. Mr. Brongniart ſays, that of Woburn melted into a ſlaggy maſs at 120° of Wedgewood's pyrometer. The variegated kind of fullers' earth (according to the late Mr. Wiedenmann's experiments,) acquired before the blow-pipe a grey, or greyiſh black colour; and a whitiſh variety, thus acted upon, became ſtill whiter: but neither of them manifeſted any ſigns of fuſion, except at the ſharp edges of the fragments. The ſame appears to hold good with all genuine varieties of this mineral ſubſtance; whence the obſervation of the late Mr. Fichtel, that the true fullers' earth "melts with great eaſe before the blow-pipe, often with ebullition and increaſe of its bulk," is undoubtedly founded in error.

Bergmann was the firſt who analyzed what he ſtyles fullers' earth, from Hampſhire; and all ſubſequent mineralogical writers have followed him in mentioning that part of England as producing the ſubſtance in queſtion: it is, however, probable that the accurate Swediſh chemiſt was miſinformed as to the county; though, from the ſatisfactory deſcription he gives of its external characters, it is ſufficiently evident that he operated on an Engliſh fullers' earth. The reſults of his analyſis were

Silica - - -	51.80
Alumine - - -	25.00
Lime - - -	3.30
Magneſia - -	0.70
Oxyd of iron - -	3.70
Water - - -	15.50.

The variety lately analyzed by Klaproth, which is well aſcertained to be from Ryegate, was found to be compoſed of

Silica - - -	53
Alumine - - -	10
Oxyd of iron - -	9.75
Magneſia - -	1.25
Lime - - -	0.50
Muriate of ſoda -	0.10
Water, &c. - -	24
Kali (a trace only)	
	98.60. Klap. Beitr. vol. iv.

We are indebted to the ſame celebrated chemiſt for an analyſis of a Sileſian fullers' earth, the external characters of which agree pretty well with thoſe of the other varieties, except that its colour is tile-red, like ſome varieties of bole, either pure, or ſpotted and veined with white and green; which colours, before the blow-pipe, give way to a marbled brown. Hundred parts of it contain

Silica - - -	48.50
Alumine - - -	15.50

Oxyd of iron - -	6.50
Oxyd of Manganeſe -	0.50
Water, &c. - -	25.50
Muriate of ſoda, (a trace only)	
	98. Klap. Beitr. vol. iv.

We mentioned above the *Lemnian earth* as a variety of the common fullers' earth; but it ſhould be underſtood that three diſtinct ſubſtances were comprized by the ancients under the name of Terra Lemnia. "Tres ejus," ſays Galen, "ſignantur differentiæ; *una* quam poſuimus terræ ſacræ, quam alii nemini, præter unam ſacerdotem, contingere fas eſt; *altera* vero ejus quæ revera Miltos eſt ſive Rubrica: utuntur autem ea potiſſimum fabri: demum *tertia* ejus extergit; qua utuntur qui lintea et veſtes lavant, quibus utique collibitum eſt." The nature of the three kinds of earth alluded to in this paſſage has been placed in a clearer light by Klaproth. The *ſecond* of them, called Miltos, was a red earth applied for the purpoſe of painting. The *third* appears to be the ſame which is mentioned by Pliny under the name of *Cimolia*, as an excellent ſubſtance for fulling: but it contains no magneſia. (See CIMOLIA.) But the *firſt* of the varieties enumerated by Galen, is the true *terra ſigillata*, recommended as early as the time of Homer for the cure of infectious diſeaſes, and ſtill celebrated in the eaſt for its imputed medicinal virtues. At the time of Dioſcorides it was mixed by the prieſts with goats' blood, and marked with a ſtamp repreſenting that animal (Σφράγις αἰγὸς): and ſtill at the preſent day this ſubſtance is dug up in the iſland of Lemnos (now Stalimene,) once a year, namely, the 15th of Auguſt, the day on which the Greeks celebrate the feſtival of the aſcenſion of the Virgin; the clergy and magiſtrates, after ſeveral previous religious ceremonies, ſuperintend the excavation of this ſubſtance, which is immediately formed into ſpindle-ſhaped balls of one ounce in weight, and marked with a ſeal bearing the name of the earth in the Turkiſh language. This ſubſtance (which ſhould not be confounded with a kind of bole of the ſame name, which is generally found nidulating in baſalt and baſaltic wackes) is of a whitiſh-grey colour, with ferruginous ſpots on its ſmooth ſurfaces. Put into water, it emits air, and ſoon crumbles into a looſe heap, exactly like the common fullers' earth, to which, notwithſtanding the ſlight difference in the reſults of the analyſis, it may, according to Klaproth's opinion, be conſidered as ſubordinate. The genuine Lemnian earth contains in hundred parts

The

FULLERS' EARTH.

The beſt fullers' earth is found in England, eſpecially Buckinghamſhire, Bedfordſhire, Surry, Kent and Nottinghamſhire. The following localities are likewiſe mentioned in the different ſyſtems of mineralogy; but we cannot vouch for the correctneſs of all of them, ſince many ſubſtances have been called by the name of fullers' earth, that, ſyſtematically ſpeaking, appear to have no claims to it. Auſtria (Karlſtein, Görtz); Croatia (Bellowar); France (Rittenau, Winterhauſen, in Alſace, &c.); Hungary (Fünfkirchen, &c.); Moravia; Neumark (Zillenzi, Droſſen); Palatinate (Kleinſtärz); Pomerania (Stargard); Saxony (Roſſwein, Johan-Georgenſtadt, Schönberg); Sileſia (Riegerſdorf, Nimptſch); Sweden (Oſmundberg); Stiria (Cilly and Thalberg); Switzerland (territory of Zurich and Berne); Tranſylvania (Thorotſko); Wirtemberg (Seeburg), &c.

The geognoſtic relations of fullers' earth are not yet ſufficiently aſcertained to enable the geologiſt to derive any general reſults from them. The relative age of the different formations appears to be as little underſtood, as the mode in which they have originated

In Saxony, where it is found in extenſive beds, it appears to owe its origin to the diſintegration of rocks of the primitive trap formation of Werner; that of Roſſwein is ſubordinate to green ſtone ſlate. In the Upper Palatinate it alternates with layers of clay and porcelain earth. In England it occurs principally in beds, and in ſtrata alternating with or reſting on ſand-ſtone, the geognoſtic relation of which is not yet determined. At Wavedon in Buckinghamſhire, on the borders of Bedfordſhire, where the pureſt ſort is found, it appears to occur in the newer fletz-formation, ſubordinate to ſand-ſtone. From the ſurface of the earth, to the depth of ſix feet, ſeveral layers of ſand are ſeen of various ſhades of reddiſh, under which there is a thin ſtratum of ſand-ſtone which reſts on the fullers' earth. The upper part of this latter, which is in contact, and mixed with the ſuperincumbent indurated ſand, is called *cledge* by the workmen, and thrown away as uſeleſs. To this ſucceeds a ſtratum of the good fullers' earth, being about eight feet thick, and ſubdivided by horizontal rifts into other layers of nearly one foot and a half in thickneſs. There is generally a ferruginous ſubſtance depoſited on the rifts, which penetrates part of the layers; and the earth, ſo tinged, is called *crop*, by the workmen, while the part unimpregnated by it receives the name of *wall-earth*. Under the fullers' earth is a ſtratum of coarſe white ſand-ſtone of about two feet thickneſs. The Engliſh fullers' earth is of much newer formation than that of Saxony; as is that of Moravia, which appears to belong to the alluvial formation.

The principal uſe to which fullers' earth is applied is indicated by its name, (ſee art. FULLING.) The quality it poſſeſſes, of depriving cloths and other ſtuffs of the greaſe and oil uſed in their preparation, appears to be derived more from the argillaceous than the other ingredients; and Mr. Kirwan thinks that the union of the lime and magneſia (which in Bergmann's opinion is chemically combined with the alumine, and not mechanically mixed, as in marls) is uſeful only as contributing to the prompt diffuſibility of this earth, which particularly qualifies it for the purpoſe to which it is applied Every clay that has ſome unctuoſity, (which manifeſts itſelf by the poliſh it receives by being rubbed with the nail,) and the ſiliceous ingredients of which are very fine, may be uſed for fulling; but it does not follow that all ſuch clayey earths as agree in theſe two characters, and in the economical advantage derived from them, ſhould of courſe occupy the ſame place in the ſyſtem. Fullers' earth was formerly an article of the greateſt importance in England, whence its exportation was prohibited under ſevere penalties; but of late it has been ſuperſeded by other ſubſtances, particularly ſoap.—K.

We ſubjoin ſome obſervations on the ſubject of fullers' earth, communicated by Mr. Farey.

"This mineral is found in three places at leaſt in the Britiſh ſeries of ſtrata, the uppermoſt of which is, in the ſand ſtrata that underlay the chalk, and are expoſed to view by the great Kent, Suſſex, and Surry *denudation*, (ſee that article,) at the foot or ſouthern ſkirt of the North Downs, at various places near Ryegate, Godſtone, &c. and from whence London is principally ſupplied with the article, though the quality of the earth and thickneſs of the ſeam (which varies much in different places) is greatly inferior to the next fullers' earth ſtratum, found near the lower part of the great ferruginous ſand ſtrata, (which Mr. Smith has denominated the Woburn ſand,) in which fullers' earth is now dug in the greateſt perfection, at Hogſtye-end in the pariſh of Waverdon, Bucks, near Woburn. Formerly it was dug alſo in Aſpley Guiſe pariſh, in Bedfordſhire adjoining, but the works there are diſcontinued. Below this ſtratum of fullers' earth, which ſometimes proves of ſeven feet in thickneſs for ſome diſtances together, is a ſingular greeniſh chertz ſtone, with a rhomboidal fracture, which ſeems very characteriſtic of this ſtratum. In diſtant counties, like Lincolnſhire, wherein we have examined it, about Bolingbroke, and to the N. and N. W. of that place, we find this and the accompanying ſtrata very ſimilar to thoſe of Bedfordſhire, although the fullers' earth is here ſo thin and imperfect in its quality, as not to be known by that name, but rather as a clay ſeam which holds up their ſprings of water in the ſand diſtrict. It may alſo be worthy of remark reſpecting this fullers' earth ſtratum, that petrified or ſiliceous wood occurs in the ferruginous ſand and ſand-ſtone below it in great plenty and perfection, and furniſhes moſt of the perfect ſpecimens of this kind from Aſpley, Crawley, and other places near Woburn, which are to be met with in the cabinets of the curious. How the ſtories of the petrifying ſprings at Aſpley which occaſioned them, as it is ſaid, came firſt into circulation, we are unable to trace; but certain it is, that the inhabitants of this village diſclaim any knowledge of ſuch ſprings or petrifying waters, except what books and credulous travellers have brought to them. It has often occurred to the writer of this, that there might, at ſome period of the earth's formation and conſolidation, have been a connection between the *ſilex* which abounds in ſuch quantity and ſo very minute a ſtate of diviſion in the fullers' earth, and that which has ſo perfectly taken the place of the pieces of wood, lodged in the ſand below it, and perhaps filled the interſtices of the chertz ſand-ſtone above mentioned; but that ſuch took effect, in too gradual a manner to be ever noticed as a petrifying ſpring on the ſurface, as the ſtories above mentioned have maintained. The examination of ſome hundreds of ſpecimens of this petrified wood in Aſpley and Crawley, ſome many feet in length, and a foot or more in diameter, has not ſeemed to furniſh data for referring any of them to the known woods of the preſent race, or to contradict the theory advanced in our article COLLIERY, of ſuch being part of the arboriferous trunks of ſub-aqueous vegetables of the primitive creation, whoſe *reliquia* they are, and by which alone their exiſtence can ever be known to us, and not fragments of any of the trees which, now, or at any period, did occupy or grow upon the *dry land* of our globe.

"In Somerſetſhire and other counties, a ſtratum occurs between the rocks of the Bath free-ſtone ſtrata, which is there called fullers' earth, and poſſeſſes its ſcouring properties;

as indeed other ſtrata do which are not called fullers' earth, particularly one in the aſſemblage of ſtrata below the chalk, called the chalk-marl; from which a ſaponaceous whitiſh clay is got, and uſed by the country people for extracting greaſe, ſcouring greaſy kettles, &c. There are doubtleſs other ſtrata in the Britiſh ſeries which poſſeſs theſe properties, in a greater or leſſer degree, but the modern improvements in chemiſtry and the arts have rendered fullers' earth, of even the beſt quality, of comparatively ſmall importance, to that which it had when particular ſtatutes were judged neceſſary for prohibiting its exportation, under the ſevereſt penalties.

"Fullers' earth has been deemed abſolutely neceſſary to the well dreſſing of cloth; and hence foreigners, though they can procure wool to be clandeſtinely exported out of the kingdom, can never reach to the perfection of the Engliſh cloths, &c. without fullers' earth, which is very plentiful in England, and excels that of other countries in quality, as much as in quantity and cheapneſs. For this reaſon it is made a contraband commodity; and the export made equally criminal with that of exporting wool."

This earth is reckoned by ſir H. Plat, and others, a great improver of land; and conſequently proper for being uſed as a manure where it is found in ſufficient quantity for that application. It is probably the moſt adapted to the more light ſorts of land.

FULLER's *Thiſtle*, in *Agriculture*, the common name of a plant cultivated in the field in ſome diſtricts, for its uſe by the manufacturers of ſome ſorts of cloth, as affording a fine vegetable hook, &c. See TEASLE.

FULLERTOL, in *Geography*, a town of Hindooſtan, in Rohilcund; 20 miles E.S.E. of Pillibeat.

FULLERTON, CAPE, a cape in Hudſon's bay. N. lat. 64° 10'. W. long. 88° 20'.

FULLERTON *Point*, a cape on the W. coaſt of the iſland of Antigua. N. lat. 17° 13'. W. long. 61° 35'.

FULLERY, a work-houſe, or place where cloths, &c. are fulled or ſcoured. The term is principally underſtood of the fulling-mill.

FULLING, the art or act of cleanſing, ſcouring, and preſſing cloths, ſtuffs, and ſtockings, to render them ſtronger, cloſer, and firmer; called alſo *milling*. See BLEACHING.

Pliny, lib. vii. cap. 56. aſſures us, that one Nicias, the ſon of Hermias, was the firſt inventor of the art of fulling: and it appears by an inſcription quoted by ſir G. Wheeler, in his travels through Greece, that this ſame Nicias was a governor in Greece in the time of the Romans.

The fulling of cloths, and other ſtuffs, is performed by a kind of water-mill; thence called a *fulling or ſcouring-mill*.

Theſe mills, excepting in what relates to the mill ſtones and hopper, are much the ſame with corn-mills. And there are even ſome which ſerve indifferently for both purpoſes; corn being ground, and cloths fulled, by the motion of the ſame wheel.

Hence in ſome places, particularly France, the fullers are called *millers*; as grinding corn, and milling ſtuffs, at the ſame time.

FULLING *Mill*, in the *Manufactures*, is a machine employed for waſhing, ſcouring, or fulling of cloth, either with a view of cleanſing it, in which caſe it is termed ſcouring, or for the purpoſe of thickening woollen cloth, worſteds, &c. when it is termed milling; in either caſe the fulling-mill employed is the ſame: its operation is to conſtantly agitate and expoſe a new ſurface to the action of water or other menſtrua, with which the goods to be operated upon are conſtantly ſupplied; this is performed by two beaters or mallets, which are ſucceſſively raiſed by the action of a water-mill, or ſteam-engine, and let fall upon the cloth, which they ſtrike and turn over in the trough where it is placed; a conſtant ſtream of water paſſing through it, carries away the dirt and impurities which are looſened from the cloths by the agitation of the mallets, or ſtocks, as they are termed.

An inſpection of *Plate* XXIX. *Mechanics*, will give a clearer idea of the conſtruction of this machine. Here *fig.* 4. is a perſpective view of a pair of ſtocks, or fulling-mill, in the action of ſcouring a piece of goods; the other figures are explanations of the parts of the machine by a ſection, *fig.* 5, and elevation, *fig.* 6. A fulling-mill generally contains four, ſix, eight, or ten pair of ſtocks, according to the quantity of work it is required to perform; theſe are all moved by the ſame water-wheel, or ſteam-engine: in the former caſe, the axis of the water-wheel is employed to move two or three pair, whilſt the others receive their motion from one of two ſimilar and parallel ſhafts, turned by cog-wheels from the ſhaft of the water-wheel. A portion of this ſhaft is repreſented at A in the plate, beneath the floor of the mill; and the cog, which gives it motion, is denoted by N, *fig.* 4: it revolves upon gudgeons at its ends, which are ſupported on braſſes reſting on the frame work or maſonry, as ſhewn in *fig.* 6. Four levers or lifters, B, B, D, D, are fitted upon the ſhaft which alternately, as they paſs the beaters E and F, lift them up, and they deſcend by their own gravity: theſe beaters are formed from a large block of wood E and F, affixed to a long ſtem G, moving on a centre at *g*, which is ſupported at the top of the frame H I K of the whole machine; the principal part of this is a large block of wood H I, hollowed out into a large cavity *a a*, for the reception of the cloth; this is termed the trough. K are pieces of wood fixed to the piece H I, and curved to a ſegment of a circle ſtruck from the centre *g*, on which the beaters move; in the ſpaces between theſe beams the ſtems G of the beaters project ſo as to be intercepted by the lifters B, D, as they revolve; the beaters are alſo curved at the loweſt ſide to the ſame circle as the beams K, ſo that they apply as cloſe as poſſible to each other without touching; this is neceſſary to prevent the cloth getting between them, and being pinched or cut thereby. The ends of the beaters, which act upon the cloth, are armed with three ſmall boards at *h*, *i*, and *k*, *fig.* 5. which project like teeth, and act more effectually to bend and diſturb every portion of the cloth placed in the trough *a a*. The beaters act very cloſe to each other ſideways, that the cloth may not introduce itſelf between them; and in the ſame manner they fit the ſides of the trough, formed by boards nailed to the block H I, and the beams K, which alſo give a great ſtrength to the machine. At one ſide theſe boards are not ſo high, for the convenience of taking the cloth out of the trough; but when the machine is in action a moveable board M, *fig.* 4. is placed on the top of the loweſt ſide, to raiſe it to the ſame height with the other, and prevent any danger of the cloth getting over. R is a pipe bringing water to the trough, and furniſhed with a ſtop cock to regulate the ſupply; the pipe paſſes through the back of the block H I, and the water ſtriking againſt a board *x*, placed before the aperture, it falls down in a ſheet upon the cloth, and keeps it conſtantly ſaturated. When the cloth is to be put into the machine, a workman with a lever ſupported on an iron hook *k* receives the beater when at the higheſt point of its motion, and prevents its deſcent; he then thruſts a long iron bolt *r*, *fig.* 6. through a hole in the beams K, and by that means retains it; the other beater is then taken up in the ſame manner, and retained

tained by the ſame bolt, being puſhed farther forwards; the looſe board M is now removed, and the cloth thrown into the trough *a a*; the beaters are then ſet in motion by removing the bolt *r*, which held them up. As the ſhaft A revolves, the lifters alternately engage one or other of the beaters which falls againſt the cloth, and, ſtriking it at the under ſide, thruſts it up into the curved part of the trough *a a*, and by that means it falls down upon the head of the beater; when the lifter raiſes the beater another time, the cloth falls into the ſpace left by its being raiſed; in this manner it continues turning the cloth over in the trough, and ſtriking it by its teeth *h, i, k*, ſo as to waſh it thoroughly. As the two beaters fall alternately, that is, one is up when the other is down, the cloth is alſo turned round diagonally in the trough: by this means, after milling a piece of cloth for ſome hours, there is little chance but that every part ſhall be ſubjected to the action of the beaters, though a whole piece is in action at once, and conſequently folded in innumerable creaſes. The water which enters at the upper end of the trough beneath the looſe board *x*, (which is intended to ſpread the water out into a thin ſheet, that it may fall equally upon the whole of the cloth,) eſcapes ſlowly through the grooves between the beam K, in which the ſtems G move, carrying with it all the filth contained in the cloth; it falls into a pit repreſented by the dark ſpace in *figs.* 5. and 6, in which the ſhaft revolves. This pit uſually has a communication with the water of the mill, to waſh away the ſediment which accumulates in the pit, from the foul water continually falling into it. The machine is fixed over this pit by a tennant at the lower part of the block H I, which is bolted between two beams L, L, ſupported on maſonry; M are two braces to ſuſtain the ends of the beams K, and keep the whole machine firmly in the ſame poſition: the beams L, L, are extended to a conſiderable length, and have three or four machines placed parallel to each other between them.

The true method of fulling with ſoap is delivered by Monſ. Colmet in an authentic memoir on that ſubject, ſupported by experiments made by order of the marquis de Louvois, then ſuperintendant of the arts and manufactories of France. The ſubſtance of which we ſhall here ſubjoin.

FULLING, *Cloth and woollen Stuffs, with Soap, Method of.* A coloured piece of cloth, about forty-five ells, is to be laid in the uſual manner, in the trough of a fulling-mill, without firſt ſoaking it in water, as is commonly practiſed in many places.

To full this trough of cloth, fifteen pounds of ſoap are required; one half of which is to be diſſolved in two pails of river or ſpring-water, made as hot as the hand can well bear it. This ſolution is to be poured by little and little upon the cloth, in proportion as it is laid in the trough: and thus it is to be fulled for at leaſt two hours; after which it is to be taken out, and ſtretched.

This done, the cloth is immediately returned into the ſame trough, without any freſh ſoap; and there *fulled* two hours more. Then taking it out, they wring it well, to expreſs all the greaſe and filth.

After the ſecond fulling, the remainder of the ſoap is melted, as the former, and caſt, at four different times, on the cloth; remembering to take out the cloth every two hours, to ſtretch it, and undo the plaits and wrinkles which it has acquired in the trough. When they perceive it ſufficiently fulled, and brought to the quality and thickneſs required, they ſcour it out for the laſt time in hot water, keeping it in the trough till it be quite clean.

As to white cloths; becauſe theſe full more eaſily, and in leſs time, than coloured ones, a third part of the ſoap may be ſpared.

FULLING *of Stockings, Caps, &c.* may be performed ſomewhat differently; viz. either with the feet or the hands; on a kind of rack, or wooden machine, either armed with teeth of the ſame matter, or elſe with horſes or bullocks' teeth.

The ingredients made uſe of herein are urine, green ſoap, white ſoap, and fullers'-earth. But water ſoftened with chalk is far preferable.

Note, woven ſtockings, &c. ſhould be fulled with ſoap alone; for thoſe that are knit, fullers'-earth may be uſed with the ſoap.

Indeed, it is frequent to full theſe kinds of works with the mill, after the uſual manner of cloths, &c. But that is too coarſe and violent a manner, and is apt to damage the work, unleſs it be very ſtrong.

FULLING, in the *Manufacture of Hats*, is the completion of *felting* (which ſee), and has for its objects the intimate connection of the fibres, and a more perfect and durable coheſion of the whole maſs. For this purpoſe the mere mechanical act of preſſure is inſufficient. In this way the reſult would be a formleſs maſs, without conſiſtence. Experience (ſays Chauſſier, cited in Nicholſon's Journal, vol. i.) has long ſhewn, that for the fulling it is neceſſary to make uſe of a bath of water heated nearly to ebullition, into which are put 10 or 15 pounds of lees of wine, for each hundred pounds of water. The heat is kept up during the whole time of working, and every three or four hours a new quantity of lees is added. Into this bath the workmen plunge their felt, and begin their ſecond proceſs. The felt is dipped in, and immediately again taken out and ſqueezed, bended and rolled, by preſſure in different directions, ſometimes with the hand defended by leather, and ſometimes by means of a roller or other ſimilar inſtrument. The immerſion and working of the felt are repeated, and the operation continued, till the ſtuff is well condenſed, and has acquired the requiſite ſolidity.

Since the operation of fulling is employed to form a denſe and compact ſtuff with the fibres or hairs, and to determine the intimate coheſion of its component parts; and ſince the mere mechanical operation is not ſufficient for this purpoſe, even with the aſſiſtance of a water-bath at the boiling heat, without the addition of lees as a neceſſary condition;—this laſt muſt be conſidered as a chemical ſolvent, which acts directly on the ſubſtance of the hairs themſelves, and produces, either by ſoftening or ſwelling them, an alteration neceſſary to inſure the coheſion of the different fibres of the ſtuff. But the lees being compoſed of the mucilaginous and colouring parts, which are ſeparated, together with a great quantity of tartar, or the acidulous tartrite of pot-aſh, it became neceſſary to aſcertain, in a poſitive manner, what might be the principle of its action. The editor of the Encyclopedié affirms without heſitation, that it is the alkali or pot-aſh of the lees which determines the fulling. But in order to ſhew (ſays Mr. C.) how erroneous this aſſertion is, nothing more is neceſſary than to dip a piece of blue paper into the bath, by which the former becomes inſtantly red; and if, after ſeveral hours' work, the ſtate of the bath be again examined, it is found that the acidulous tartrite of pot-aſh is partly exhauſted, and the workmen ſoon perceive, from the difficulty of continuing their work, that a new quantity is required to be added. And again, if we conſider the ſparing ſolubility of the acidulous tartrite of pot-aſh in cold water, it is eaſily ſeen why in this proceſs the water muſt be kept nearly boiling. Whence

it is evident that it muſt act by the portion of acidate which it contains. Hence our author was induced to think, that the ſulphuric acid might be advantageouſly ſubſtituted in the place of the lees; and as 12 pounds of lees are uſually added to 100 of water, he eſtimated by approximation that one gros of ſulphuric acid would be equivalent to at leaſt one pound of the lees, and conſequently that 12 gros of ſulphuric acid would be ſufficient for 100 pounds of water. His conjectures were ſoon confirmed by experiment; and after a fair trial it was aſcertained that the uſe of the ſulphuric acid is much preferable to that of wine-lees; that it is not only much more economical, but ſtill more convenient in the uſe; and, what is yet more important, the health of the workmen is not injured by the exceſs and duration of the heat, the thick vapours, and the diſguſting odour, which exhales from the bath, particularly when the lees have been altered by mouldineſs and putrefaction, which is very common in theſe manufactories. When the ſulphuric acid is employed, it is uſeleſs to keep the bath nearly boiling, as was formerly done. A degree of heat of 25 or 30 degrees (90° or 100° of Fahrenheit) is ſufficient for good fulling. The ſaving of fuel is an object of importance in manufactories; and as very little fire is neceſſary when ſulphuric acid is uſed, cauldrons of lead may be ſubſtituted inſtead of copper-boilers, the firſt coſt and annual repair of which are very conſiderable.

The felts prepared by this new proceſs are alſo of a very ſuperior quality to thoſe which have been worked in the bath with wine-lees. In fact, the mucilaginous and colouring matters of the lees, which are ſuſpended in the bath, penetrate the texture of the ſtuff, and adhere with more or leſs force; and when, after having paſſed the hats through the dye, they are beaten, a fine black duſt flies off in great abundance, which not only weakens the texture of the felt, but by diffuſing itſelf through the manufactory greatly incommodes the workmen, and frequently occaſions coughs and diſorders of the throat.

Hats felted in this manner, ſays a manufacturer who had adopted this proceſs, are not only clear of the powder which abounds in the others, but they take the dye better, and are cleaner.

FULLONIANI, in *Church Hiſtory*, heretics who anathematized all who did not acknowledge, that Chriſt ſuffered in his divine nature; or who diſtinguiſhed his human and paſſible nature from his divine and impaſſible.

FULLONICA *Terra Alba*, white fullers' earth, in natural hiſtory, a name given by ſome authors to the common white tobacco-pipe clay. See CIMOLIA, and PIPE-CLAY.

FULLONUM CARDUUS. See TEAZEL.

FULMAR, in *Ornithology*, a ſpecies of procellaria, or petrel, (the PROCELLARIA GLACIALIS, which ſee,) that inhabits the iſle of St. Kilda; appearing there in November and continuing through the whole year, except the months of September and October. It lays a large white and brittle egg, which is hatched in June. This bird is ſuperior in ſize to the common gull; the bill is ſtrong, hooked at the end, and of a yellow colour. The noſtrils are compoſed of two large tubes, lodged in one ſheath; the head, neck, inferior part of the body, and tail are white; the back and coverts of the wings aſh-coloured; the quill-feathers duſky, and the legs yellowiſh. Inſtead of a back toe, it has only a ſort of ſpur, or ſharp ſtraight nail. The ood of theſe birds is the blubber or fat of whales, of which they are very voracious; inſomuch that the whales are diſcovered at ſea by the flights of theſe birds; this is ſoon converted into oil and ſpouted from their bills in large quantities for their defence, and for the ſupply of their young. This oil, it is ſaid, has been ſucceſsfully uſed in rheumatic caſes. The fulmar is of ſingular uſe to the iſlanders, as it ſupplies them with oil for their lamps, down for their beds, a delicacy for their tables, a balm for their wounds, and a medicine for their diſeaſes. The fulmar is alſo a certain prognoſticator of the change of the wind; becauſe, if it comes to land, no weſt wind is expected for ſome time; and the contrary, when it returns and keeps at ſea. Pennant.

FULMINANT, FULMINANS, or *Fulminating*, an epithet applied to ſomething that thunders, or makes a noiſe like that of thunder.

We ſay, "Jupiter fulminans, aurum fulminans, pulvis fulminans, &c." The Jupiter fulminans and the Jupiter fulgurator ſeem to have been very much of the ſame kind: but if they are diſtinguiſhed, we may conſider the former as the diſpenſer of the lightnings which are darted from the clouds, and the latter as the diſpenſer of thoſe leſſer lightnings that only ſhoot about and ſtruggle amidſt the clouds.

FULMINANS, *Aurum*. See AURUM.

FULMINANS, *Pulvis*, is a compoſition of three parts of nitre, two parts of purified pearl-aſh, (kali præparatum, Lond. Pharm.), and one part of flowers of ſulphur. The parts are to be well mixed in an earthen mortar, and placed on a tile or plate before the fire, till it is perfectly dry; and if it be transferred, while hot, into a bottle with a ground ſtopper, it may be kept for any time without injury. Its effects are exhibited by pouring from 10 to 40 grains into an iron ladle, placed over a ſlow fire, in which caſe it will ſoon acquire a brown colour, and the conſiſtence of paſte; a blue lambent flame will appear on its ſurface; and immediately afterwards, the whole compoſition will explode with a ſlight momentary flaſh, and a loud noiſe. The maſs being removed from the fire as ſoon as it is fuſed, may be kept in a dry, well cloſed phial, and it will at any time be exploded by a ſpark, and burn like gun-powder, but more rapidly and with a greater detonation; but this effect cannot be produced on the unmelted powder, however accurately its ingredients may have been mixed. Whilſt the powder is in fuſion, but not ſufficiently heated to produce the blue flame, a particle of ignited charcoal thrown upon it, will immediately occaſion a very loud exploſion. The fulminating property of this powder is acquired by fuſion, or when the pot-aſh and ſulphur form ſulphuret of pot-aſh. It may therefore be prepared by mixing ſulphuret of pot-aſh with nitre, inſtead of adding the ſulphur and alkali ſeparate.

FULMINATING DAMP. See DAMP.

FULMINATING *Legion*. See THUNDERING *Legion*.

FULMINATION, in the *Romiſh Canon Law*, a ſentence of a biſhop, official, or other eccleſiaſtic appointed by the pope; whereby it is decreed, that ſome bull, diſpenſation, or reſcript, ſent from the pope, ſhall be executed.

Fulmination is the ſame thing with the verification, or recognition, of a letter, or inſtrument, of a prince in a lay court.

FULMINATION is alſo uſed for the denunciation or execution of a ſentence of anathema, made in public, with due ſolemnity. See ANATHEMA.

In fulminating anathemas, the biſhop who pronounces ſentence is to be clothed in his epiſcopalia, and accompanied with two prieſts, in ſurplices; after ſentence is pronounced,

nounced, they caſt down to the ground the lighted wax-tapers which they held in their hands.

FULMINATION, or *Fulguration*, in *Chemiſtry*, a vehement noiſe, or ſhock reſembling thunder, occaſioned by the ſudden exploſion and inflammation of divers preparations; as *aurum fulminans*, &c. when ſet on fire.

FULNECK, in *Geography*, a village ſituated at a ſmall diſtance from the high road, leading from Leeds to Bradford, 4½ miles from the former place, in the wapentake of Morley, and in the weſt-riding of the county of York, is remarkable for a ſettlement of numerous perſons, belonging to a ſingular ſect of Chriſtians, called, on account of their tenets, the Unitas Fratrum; and Moravians, becauſe firſt founded by count Zinzendorf, in the province of Moravia. The place, originally named Lamb's-hill, had its preſent denomination given to it by the new inhabitants. The ſettlement is pleaſantly ſituated on the ſlope of a riſing ground, at the foot of which runs a meandering ſtream. It conſiſts chiefly of two long ſtreets, the houſes of which are neatly built, and an elegant ſtructure near the centre contains a chapel and ſeminary. There are two inſtitutions nearly reſembling a monaſtery and nunnery, which go under the ſingular appellations of "The Young Men's Economy, and the Young Women's Economy." No ſtrangers of the oppoſite ſex are admitted in either houſe, but the inhabitants may occaſionally come out to converſe with their friends. They are allowed to follow any buſineſs moſt eligible to themſelves, and, fixed by no vows, they are at liberty, whenever they pleaſe, to change their way of life. The number of women is about ſixty, who are principally occupied in ſpinning, tambour, and embroidery, and they ſleep together in one large room. The men, who amount to about fifty, ſleep alſo in a common dormitory, and are chiefly employed in the different branches of the clothing trade.

Originally the number of ſettlers of this perſuaſion was upwards of four hundred, but the population of Fulneck has been latterly on the decline. Many who at firſt joined for the ſake of novelty have ſeceded; and the ſeparation of the ſexes, according to the principles of their founder, and the rules adopted by themſelves, together with their peculiar management in conducting trade, is little calculated, either to increaſe population or extend manufactures.

FULNECK, a town of Moravia, in the circle of Prerau, is a place of conſiderable importance in the Moravian church; 21 miles N.E. of Prerau. N. lat. 49° 37'. E. long. 17° 51.

FULTA, a town of Hindooſtan, in Bengal, on the E. ſide of the Hoogly; 24 miles S.S.W. of Calcutta.

FULTAWARY, a town of Hindooſtan, in Bengal; 26 miles N. of Purneah.

FULUSCULUM, in *Botany*, a name given by the ancient Romans to a peculiar ſpecies of mullein or verbaſcum, of which they uſed to make the wicks of the torches with which they kindled their funeral piles. The Greeks for the ſame reaſon called this ſpecies necuia. Dioſcorides indeed calls it *lychnitis*, λυχνιτις; and Nicander, *thryallis*, θρυαλλις. The way they uſed it was thus; they beat out the ſtalk of the plant, as we do hemp, and when it was ſeparated into looſe fibres, they plunged it into melted reſin; this gave it a conſiſtence again, and when cold, it was a kind of flambeau.

FULWAR, in *Geography*, a town of Hindooſtan, in the ſoubah of Lahore, on the Setledge; 100 miles S. E. of Lahore.

FUMADOES, in *Commerce*, a name given to pilchards, garbaged and ſalted, then hung in the ſmoke and preſſed; ſo called in Spain and Italy, whither they are exported in great abundance. Vid. Stat. 14 Car. II. cap. 31.

FUMAGE, a term uſed in ſome parts of the kingdom, for dung, or manuring with dung.

FUMAGE. See FUAGE.

FUMANI, ADAM, in *Biography*, was born at Verona in the ſixteenth century, and by his ſkill and acquirements in the ancient languages, he obtained the friendſhip of the moſt eminent ſcholars of his time. He accompanied cardinal Pole in his legation to Flanders, and Navagero to the council of Trent, to which aſſembly he was appointed ſecretary. He held likewiſe ſome church preferment. He tranſlated from the Greek into Latin the works of St. Baſil. He compoſed many poetical pieces, of which the moſt remarkable was "A Syſtem of Logic," in Latin heroics, in five books, which he treated with an elegance and eaſe which are altogether ſurpriſing, and prove the author's facility in the management of verſe and language. It was not printed till the year 1739, in an edition of the works of Fraſcatorius. Moreri.

FUMARIA, in *Botany*, from *fumus*, ſmoke, it having been called by old writers *fumus terræ*, ſmoke of the ground, we know not for what reaſon. Hence the Engliſh name, Fumitory. Linn. Gen. 849. Schreb. 1154. Willd. Sp. Pl. v. 3. Mart. Mill. Dict. v. 2. Juſſ. 237. Claſs and order, *Diadelphia Hexandira*. Nat. Ord. *Corydales*, Linn. *Papaveraceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of two equal, ſmall leaves, moſtly deciduous, often coloured. *Cor.* tubular, ringent, of two petals, each lobed and ſpreading at the extremity, gibbous, and holding honey at the baſe, variouſly formed in different ſpecies. *Stam.* Filaments ſix, capillary, united into two ſets by their broad, elongated, membranous baſes, ſheathing the germen; anthers ſmall, roundiſh, vertical. *Piſt.* Germen roundiſh or oblong; ſtyle curved or oblique; ſtigma obtuſe. *Peric.* Pod of two valves, and one cell. *Seeds* one or more, roundiſh.

Eſſ. Ch. Calyx of two leaves, inferior. Corolla ringent, gibbous and honey-bearing at the baſe. Each filament bearing three anthers.

Obſ. This genus, as underſtood by Linnæus and his followers, is extremely natural, but the ſeed-veſſel is ſo very different in many of the different ſpecies, that Gærtner, whoſe ſtudies were peculiarly directed to that part of the fructification of plants, has, on this principle alone, ſeparated *Fumaria* into ſeveral new genera. We are more diſpoſed to agree with Linnæus, eſpecially as the ſeed-veſſels in queſtion ſeem to us, in many caſes, to differ rather in appearance than in reality.

Some ſpecies of *Fumaria* have a ſingle protuberance at the baſe of the corolla, others a double one, which in a few becomes a ſpur. Six of the former diviſion are natives of Britain, but none of the latter. *F. ſolida*, Engl. Bot. t. 1471, is common in gardens, though rarely wild with us. It flowers in the ſpring, and mixes prettily with harebells, anemonies and daffodils. *F. lutea*, t. 588, found on rocks and old walls in the north, is a doubtful native, but very frequent in gardens, where it ſoon becomes a weed. Theſe two have a many-ſeeded pod. The vulgar *F. officinalis*, t. 589, and the rare *F. parviflora*, t. 590, and *capreolata*, t. 943, all agree in their elegant little pink bloſſoms, variegated with ſpots of dark red and of green, as well as in having round ſingle-ſeeded pods. *F. claviculata*, t. 103. has green and white flowers, and a very delicate climbing herbage. Its pods have ſeveral ſeeds, but its cloſe generic affinity to the three preceding cannot be diſputed.

The exotic *Fumariæ* are ſeveral. Among thoſe with two protuberances at the baſe of the flower is *F. ſpectabilis*, a native of Siberia or Tartary, as far as we can diſcover. It is cultivated by the Chineſe, and ſometimes ſeen among their drawings

drawings of ornamental plants, being extremely handſome. A figure is given of this ſpecies in the ſeventh volume of the *Amœnitates Academicæ* from a ſpecimen in the Linnæan herbarium, the only one we have ever met with in any collection. A very elegant Siberian ſpecies has been ignorantly called *ſpectabilis* in the Engliſh gardens, and is figured by Mr. Andrews in his Repoſitory. This has much ſmaller flowers and leaves than the true one, but deſerves cultivation, as it thrives well in peat earth in the open ground, and bloſſoms abundantly. The American *F. ſempervirens*, conſpicuous for its glaucous leaves, and red and yellow corolla, is alſo a very pretty garden plant.

FUMARIA, in *Gardening*, comprehends plants of the tuberous-rooted low-flowery perennial kind; of which the ſpecies moſtly cultivated are, the naked ſtalked fumitory (F. cucullaria); the glaucous fumitory (F. ſempervirens); the yellow fumitory (F. lutea); and the white-flowered fumitory (F. capnoides.)

Theſe plants are deſerving of ſituations in the flower-garden, and different compartments of ornamented grounds, as the fore-parts of clumps, borders, &c.

Method of Culture.—Theſe plants muſt be raiſed in different ways according to the kinds. The firſt ſort is readily increaſed by planting the off-ſets taken from the old roots in a light ſoil where the ſituation is rather ſhady, in the early part of the autumn, as ſoon as the old ſtems begin to decay. They ſhould afterwards be kept perfectly free from weeds.

All the other ſorts are capable of being raiſed by ſowing the well-ripened ſeeds in ſituations where the plants are to grow. They afterwards only require to be kept perfectly clean from weeds.

FUMARIA, in the *Materia Medica*, was by the ancients named "Capnos," becauſe it was thought to be peculiarly uſeful in dimneſs of ſight, and other diſeaſes of the eyes. The leaves, which are the part of the plant directed for medicinal uſe by the Edinburgh college, are extremely ſucculent, and have no remarkable ſmell, but a bitter, ſomewhat ſaline taſte. Fumitory has been ſuppoſed by ſeveral phyſicians of great authority, both ancient and modern, to be very efficacious in opening obſtructions, and infarctions of the viſcera, particularly thoſe of the hepatic ſyſtem; it is alſo highly commended for its power of correcting a ſcorbutic and acrimonious ſtate of the fluids, and has therefore been employed in various cutaneous diſeaſes: when taken in pretty large doſes it proves diuretic and laxative, eſpecially the juice, which may be mixed with whey, and uſed as a common drink. Dr. Cullen claſſes this plant among the tonics. Its remarkable virtues, he ſays, are thoſe of clearing the ſkin of many diſeaſes, and he experienced its good effects in many inſtances of cutaneous affections, which he would call lepra. He commonly uſed it by expreſſing the juice, and giving that to the quantity of two ounces twice a day. He adds that the virtues remain in the dried plant, ſo that they may be extracted by infuſion or decoction, in water; and the foreign diſpenſatories have prepared an extract of it, to which they aſcribe all the virtues of the freſh plant. An infuſion of the leaves is uſed as a coſmetic, to remove freckles and clear the ſkin. Woodville Med. Bot.

FUMAY, in *Geography*, a town of France, in the department of the Ardennes, and chief place of a canton in the diſtrict of Rocroy. The place contains 1740, and the canton 6795 inhabitants, on a territory of 240 kiliometres in nine communes. The principal article of its trade is ſlates, of which there are quarries near the town. N. lat. 50°. E. long. 4° 44'.

FUMBO, one of the Querimba iſlands in the Indian ſea. S. lat. 13° 6'.

FUMEL, a town of France, in the department of the Lot and Garonne, and chief place of a canton in the diſtrict of Villeneuve-d'-Agen, 9 miles E.S.E. of Montflanquin. The place contains 2079, and the canton 8465 inhabitants, on a territory of 167½ kiliometres in 8 communes.

FUMEN, a town of Perſia, in the province of Ghilan; 10 miles N.W. of Reſhd.

FUMET, a term uſed among ſportſmen for the ordure or dung of harts: otherwiſe called fewmets.

FUMIGATION, in *Medicine*, the diffuſion of various ſubſtances in the form of vapour or gas, with a view to correct the air, when vitiated by the putrefaction of animal and vegetable matter, or by contagious effluvia.

As the air has been liable to vitiation by fœtid and offenſive effluvia, from the time that men were in the habit of aſſociating in numbers; ſo, from the earlieſt ages, the diffuſion of other effluvia, whether of a fragrant or a pungent quality, through the air, as an antidote to its diſagreeable or unwholeſome qualities, has been often reſorted to. We have already obſerved, that Hippocrates and Acron of Agrigentum, when the plague raged at Athens, ordered large piles of wood to be burnt in the ſtreets, with a view of correcting the ſuppoſed vitiated condition of the atmoſphere. (See CONTAGION.) The ſame expedient has been reſorted to in modern times, during the prevalence of the plague in London, Marſeilles, Toulon, &c. ſo that theſe cities were enveloped in a cloud of ſmoke for two or three days; but in London a great increaſe in the number of deaths took place on the night following; and at Marſeilles, the hiſtorian obſerves, this ſmoke augmented the natural heat of the climate and ſeaſon, and ſeemed to increaſe the activity of the contagion. (Papon, de la Peſte, &c. tom. i. p. 234.) The burning of wood, indeed, produces an acid, which has been hence denominated the *pyro-ligneous acid*, and which is ſufficiently obvious from the ſmarting ſenſation which the ſmoke of wood occaſions in the eyes; but experience proves its operation in deſtroying contagion to be comparatively feeble. The effect of a dry confined heat in purifying clothes, or other fomites, from the contagious matter which they may contain, as mentioned by Dr. Lind, depends altogether upon another operation of heat, diſtinct from fumigation by the vapours of the ſubſtances burnt. But M. Guyton Morveau has remarked, that the burning of three truſſes of ſtraw in the cell of a priſon, in a moſt intolerably offenſive condition, did not remove the putrid ſmell. (Traité des Moyens de deſinfecter l'Air, p. 12.)

Next to the burning of wood, the vapours of burning ſulphur have been generally employed with a view to deſtroy the matter of contagion. This vapour is the ſulphureous acid gas, or volatile vitriolic acid of the old chemiſts; and its efficacy in the deſtruction of contagion has been long eſtabliſhed; but as, even in ſmall quantity, it affects the reſpiration of animals, and in larger quantity will occaſion ſuffocation and death, it can only be employed for fumigating clothes, furniture, or empty apartments, to the individual parts of which the fumes can be directly applied.

The deflagration of gunpowder was eſteemed "next to the ſmoke of wood for purifying a tainted air," by Dr. Lind, (On Fevers and Infections, p. 51.) But the products, which it yields, are inadequate to the deſtruction of the contagious miaſms. Perhaps its principal operation conſiſts in giving movement to a large maſs of air, and thus diſplacing ſome of the contagious effluvia, without deſtroying them, or in diffuſing them through a larger volume of air, and therefore weakening their force. The deflagration of nitre was tried by Dr. Carmichael Smyth in the hoſpital wards at Wincheſter, upon the notion that nitrous acid

was

was diſengaged by the combuſtion; but a farther acquaintance with chemiſtry convinced him of his miſtake. (See his Deſcript. of the Jail Diſtemper, &c. p. 174.)

With reſpect to all perfumes, and other aromatic, reſinous, and balſamic ſubſtances, they are utterly proſcribed upon the authority of general experience. "It is obvious," ſay the intelligent authors of a pamphlet of inſtructions for the people, publiſhed during an epidemic in France, "that theſe ſtrong ſmelling ſubſtances are far from poſſeſſing the wonderful properties attributed to them; in fact, they afford a treacherous ſecurity. This vapour furniſhes no new air; exerting no action on that with which it mingles, it ſerves only to conceal the bad ſmells, without deſtroying them." (Morveau, loc. cit. p. 158.) This is to put a maſk on the enemy, and then to miſtake him for a friend. By ſeveral direct experiments, M. Morveau aſcertained the feeble powers of the vapours of various odoriferous and volatile ſubſtances, in deſtroying or concealing the offenſive exhalations ariſing from putrid animal matter. He found that by burning benzoin, &c. by ſpirituous ſolutions of this reſin, and of the balſam of Peru, of ſtyrax, and of myrrh, the odour of theſe ſubſtances was only mixed with that of the putrid matter; and however predominant it was, it did not prevent him from diſcerning the preſence of the putrid air by an exceſſively diſagreeable faint ſmell. (Loc. cit. Exper. XII—XV.) The ſame obſervation is applicable to the vapour of tar, which Dr. Lind imagined was poſſeſſed of ſome efficacy.

The acetous acid, or common vinegar, when evaporated by heat, has been often employed as a fumigation in infected apartments; and the experiments of the intelligent French chemiſt, juſt mentioned, evince that it is poſſeſſed of ſome little power in diminiſhing the fetid odour of putrid air. The acetic acid, or radical vinegar, as it has been called, is more efficacious in removing the offenſive properties of this air. He obſerves, however, that its powers are limited to a very ſmall ſpace; and therefore that, although it may be uſeful about the perſons of thoſe who are compelled to be much about the ſick, it is altogether inadequate to the purification of large rooms; not to mention the great expenſe of its preparation. When the fumes of vinegar are attempted to be obtained by throwing it on burning coals, the greater part of the acid is actually decompoſed, and therefore its efficacy is in a great meaſure loſt. The anti-peſtilential vinegar, or "vinegar of the four thieves," which has been greatly extolled, was found very ineffectual in correcting the putrid air with which it was agitated: indeed as the aromatic ſubſtances, from which its pretended virtues were ſaid to be derived, are themſelves inefficacious, the combination could not be expected to be poſſeſſed of much power.

In thoſe mineral acids, however, which are capable of being converted into vapours, modern reſearch has diſcovered very efficacious agents, it would appear, for deſtroying the matter of contagion; ſuch are the nitrous or rather nitric acid gas, the muriatic, and the oxygenated muriatic acid gas. The e gaſes not only have the advantage of decompoſing the miaſms of contagion, but alſo of being reſpirable in a ſtate of moderate dilution or diffuſion, ſo as to admit of being uſed in the wards of hoſpitals, or other inhabited apartments. There has been ſome controverſy with regard to the priority of the diſcovery of the anti-contagious property of the vapours of theſe mineral acids, in conſequence of a parliamentary reward of 5000 pounds having been given to Dr. Carmichael Smyth for the diſcovery. Of the three individuals, who may poſſibly have each been led to the experiment without any aſſiſtance from the other, it ſeems to be certain that Dr. Smyth was the laſt to reſort to it; although he was perhaps the firſt to employ one of theſe acid vapours, *viz.* the nitrous. It has been ſhewn, we think ſatisfactorily, by Dr. John Johnſtone, of Birmingham, that his father, Dr. James Johnſtone, ſenior, had employed the vapour of muriatic acid in an epidemic fever at Kidderminſter in the year 1756, and recommended it in "An hiſtorical Diſſertation" concerning that epidemic, publiſhed in 1758. (See a pamphlet entitled, "Account of the diſcovery of the mineral acids in a ſtate of gas to deſtroy contagion," 1803: alſo, a "Reply to Dr. J. C. Smyth, &c." 1805.) In the year 1773, M. Guyton de Morveau, of Dijon, publiſhed an account of the efficacy of the vapour of muriatic acid, in purifying the putrid air of a church in that city, which had been rendered uſeleſs, and was ſhut up, in conſequence of the opening of ſome vaults within it. (See Rozier, Journal de Phyſique, tom. i. p. 436. Juin, 1773.) This ingenious chemiſt appears to have been led to the experiment upon a piece of hypotheſis, that the muriatic acid gas would neutralize the ammoniacal ſalts, which are generated during putrefaction. The experiment ſucceeded perfectly, and the tainted air, before intolerable to reſpiration, was completely deprived of its offenſive qualities. It was not until the year 1795, that Dr. Smyth recommended the nitrous acid gas as the means of deſtroying contagion, and directed an experiment which was made in the Union, a hoſpital-ſhip, and again in part of the Ruſſian ſquadron, at Sheerneſs. The ſucceſs of this experiment was nearly as complete as that of M. de Morveau, at Dijon. The immediate effect of the fumigation was to deſtroy the offenſive ſmell ariſing from ſo many ſick crowded together; none of the attendants were afterwards attacked with the fever; and the general ſtate of the ſhip was ſpeedily improved. (See Report of the experiments, &c. by Mr. A. Menzies.)

Such is the hiſtory of this diſcovery; and the efficacy of the nitrous and muriatic fumigation has been confirmed by the ſubſequent experience of other naval medical officers, and of the phyſicians to the houſes of recovery for contagious fever, eſtabliſhed in various parts of the kingdom. It remains for us, therefore, to deſcribe the mode in which the fumigation is performed.

"To obtain the nitrous or marine acid, in a ſtate of vapour," Dr. C. Smith obſerves, "the method is extremely ſimple. It conſiſts in decompoſing nitre or common ſalt, by means of heated vitriolic acid, which may be done as follows. Put half an ounce of vitriolic acid" (the undiluted ſulphuric acid, or oil of vitriol of commerce) "into a crucible, or into a glaſs or china cup, or deep ſaucer; warm this over a lamp, or in heated ſand, adding to it from time to time ſome nitre or common ſalt: theſe veſſels ſhould be placed at twenty or thirty feet diſtance from each other, according to the height of the cieling or virulence of the contagion." (Smyth on the Jail Diſtemper, p. 198.) With reſpect to the nitric acid vapour, however, it was obſerved by Dr. Odier of Geneva that, when heat was employed, it was extremely difficult to avoid the extrication of the red fumes of nitrous acid, which are very injurious to reſpiration; and that by mixing the ingredients cold, an equal quantity of the vapours of nitric acid was obtained. In the Houſe of Recovery, in London, this method is purſued, and the following formula is adopted in the fumigation of ſmall apartments, "Take an equal quantity of powdered nitre and ſtrong vitriolic acid or oil of vitriol (about ſix drachms of each are ſufficient); mix them in a tea-cup, ſtirring them occaſionally with a tobacco-pipe or piece of glaſs; the cup muſt be removed occaſionally to different parts of the room, and the

fumes

fumes will continue to ariſe for ſeveral hours. The oil of vitriol ſhould be taken by meaſure, not by weight." (See Reports of the Fever Inſtitution.) On board the Union, hoſpital-ſhip, the mixed ingredients in the cup were carried about the ſhip in earthen pipkins containing hot ſand. M. Morveau informs us that the muriatic fumigation, when common ſalt, or muriate of ſoda, is employed, may alſo be effected without the aid of heat. M. Morveau conſiders the oxy-muriatic acid vapour, however, as the moſt effectual deſtroyer of contagion; but Dr. Smyth was led to reject this acid, from a notion that it was not reſpirable, and therefore could not be employed in inhabited apartments: both the experiments of Morveau, however, and of Mr. Cruikſhank, of Woolwich, have ſhewn the ſafety and practicability of uſing this acid gas in fumigation. The following are the quantities and proportions of the neceſſary ingredients, which M. Morveau employed in a ward, containing ten beds.

	oz.	gros.	gr.			
Common ſalt - -	3	2	10	or	10	decagrams.
Black oxide of manganeſe	0	5	17	—	2	
Water - - -	1	2	35	—	4	
Sulphuric acid - -	1	7	50	—	6	

The oxide is firſt reduced to powder, and then mixed with the ſalt by trituration; this mixture is then put into a glaſs or china veſſel, and the water added; laſtly, the acid is poured upon thoſe ingredients, at once, if the fumigation is made in uninhabited apartments; but in ſucceſſive portions if the rooms are inhabited. The following proportions were employed by Mr. Cruikſhank.

Muriate of ſoda - -	2 parts
Oxide of manganeſe -	1
Water - - -	1½

Sulphuric acid of 36 degrees 2. (See Rollo on Diabetes.)

M. Morveau, who is ſatisfied that oxygenated muriatic acid gas is the moſt efficacious preſervative againſt infection, "l'anti-contagieux par excellence," ſuggeſts a mode of obtaining this gas extemporaneouſly; *viz.* by pouring upon a drachm of the oxide of manganeſe, in a four ounce bottle, about 2½ ounces of the nitro-muriatic acid. The vapour of the oxy-muriatic acid is immediately diſengaged in conſiderable intenſity.

Although theſe mineral acid vapours are obviouſly poſſeſſed of the power of deſtroying putrid effluvia, and the contagious miaſms ariſing from typhoid fevers, dyſentery, foul ulcers, &c.; the extent of their power upon the contagious matter of ſmall-pox, ſcarlet-fever, meaſles, &c. is not yet ſufficiently aſcertained. The only evidence with which we are acquainted relative to this part of the ſubject, is the following obſervation of Dr. Smyth. After ſtating that in ordinary caſes, and in private practice, he found that one, two, or three fumigating lamps, by which a conſtant fumigation is kept up, night and day, ſo as to paſs over the beds of the ſick, are perfectly ſufficient, he adds: "In this manner I have not only ſtopped the common contagion in the hoſpital and in private, but I have equally ſucceeded, which is of great conſequence to be known, in preventing the ſcarlatina anginoſa, or putrid ſore throat, from being communicated to the reſt of the family, living under the ſame roof. Whether this will apply to the ſmall pox, I cannot ſay from my own experience; but I have been told by Dr. Rollo, ſurgeon to the artillery, and Mr. Cruikſhank, profeſſor royal of chemiſtry to the academy at Woolwich, that it deſtroys the miaſma of ſmall pox; and that of two quantities of matter, taken for the purpoſe of inoculation, one was expoſed to the nitrous vapour, the other not: the perſons inoculated with the firſt were not ſeized with the diſeaſe, whilſt the inoculation took the uſual effect, when performed with the ſecond." (See Dr. Smyth's treatiſe "On the Effect of the Nitrous Vapour," &c. p. 221.)

FUMIGATION, *Powder of*, was invented at Moſcow, in 1771, for preventing the infection of the plague. It is prepared of different degrees of ſtrength in the following manner: 1. Take leaves of juniper, juniper-berries pounded, ears of wheat, guaiacum wood pounded, or, if this cannot be had, the cones of pines or firs, of each ſix pounds; common ſalt-petre pounded, eight pounds; ſulphur pounded, ſix pounds; Smyrna tar or myrrh, or, inſtead of this, the common tar of pines and firs, two pounds; mix all theſe ingredients together, and they will produce a pood of the powder of the firſt ſtrength. 2. Take ſouthernwood or mugwort, cut into ſmall pieces, five pounds; leaves of juniper, cut in the ſame manner, four pounds; juniper-berries pounded, three pounds; common ſalt-petre pounded, four pounds; ſulphur pounded, two pounds and a half; Smyrna tar or myrrh, one pound and a half; mix theſe together, and they will yield half a pood of the powder of the ſecond ſtrength. The efficacy of the powder of fumigation was tried on ten malefactors under ſentence of death, who were confined three weeks in a lazarette, and expoſed in every poſſible way to the infection of the plague, and none of them were at all injured by it.

FUMIGATION is alſo uſed for the act of making a ſuſpended body receive the fumes of or ſteams of one or more other bodies, in order to calcine, to correct it, or impart to it ſome new quality.

Ceruſs is made by the fumigation, or vapour, of vinegar, gnawing and corroding plates of lead.

FUMIGATION, is a practice, in *Surgery*, of applying remedies, in the form of ſmoke, to the ſurface of the body, or to that of ulcers, tumours, &c. It is one of the moſt ancient plans of affecting the conſtitution with mercury, and Lalonette and Albernethy have ſtated circumſtances in its favour, which certainly render it ſometimes a very eligible mode. The latter is of opinion, that if the peculiar advantages of mercurial fumigations were generally known to practitioners, they would be much more frequently employed. The advantages of the method conſiſt in its affecting the conſtitution, when other means have failed, and in producing its effects in a much ſhorter time than any other mode requires. How deſirable this celerity of operation muſt often be, when venereal ulceration is making great ravages in the palate, throat, &c. it is needleſs to inſiſt upon. In patients, who have not ſtrength to rub in ointment, and whoſe bowels will not bear the internal exhibition of mercury, the mode of fumigation may prove of great ſervice.

"In the year 1776, the Chevalier Lalonette, a phyſician at Paris, laid before the public an account of a new mode of mercurial fumigation, free from the inconveniences of former ones, and which, in the ſpace of thirty-five years, he had ſucceſsfully employed in more than four hundred caſes, that had reſiſted all the ordinary methods of cure. His method conſiſted in incloſing the patient, previouſly undreſſed, in a kind of box reſembling a ſedan-chair, with an opening at the top to let out the head, and another at the bottom, to which was fitted a ſmall grate or furnace, having in it a heated iron for converting the mercurial remedy into fume. The preparation he made uſe of was a kind of calomel, which, by repeated ſublimation from iron filings, was ſo far deprived of its muriatic acid, as to be in part reduced into running quickſilver; and while it poſſeſſed conſiderable volatility, was perfectly unirritating. Some of this powder, being ſtrewed upon the hot iron placed below, was immediately converted into ſmoke, which ſurrounded the patient's

body, and after ſome time ſettled on his ſkin in the form of a white and very fine calx of quickſilver: a complete dreſs, having its inner ſurface fumigated with the ſame powder, was then put on. The remedy, being thus generally applied to the mouths of the cutaneous abſorbents, ſoon got admiſſion into the circulating fluids, and the conſtitution became thereby more ſpeedily affected, than by any other proceſs known before." (Abernethy's Surgical and Phyſiological Eſſays, part 3.)

As the fumigating powder uſed by M. Lalonette was very operoſe, and conſequently a very expenſive preparation, and appeared to have no advantages over one made by abſtracting the muriatic acid from calomel by means of volatile alkali, Mr. A. has always employed the latter, which is prepared at the hoſpital in the following manner: Two drachms of aqua ammoniæ are added to ſix ounces of diſtilled water, and four ounces of calomel are thrown into this liquor, and ſhaken up with it; the powder is afterwards ſeparated by a filter, and dried.

The powder thus obtained is of a grey colour, and contains a good deal of quickſilver in its metallic ſtate, which of courſe is extremely volatile, but becomes oxydated when raiſed into fume, and afterwards condenſed into a white ſubtile powder.

Mr. A. never knew this method fail in curing the lues venerea.

In local diſeaſe of the joints, ſuch, for inſtance, as frequently takes place in the knee, and in ſarcomatous enlargements of the breaſt in women, Mr. Sharp, and ſir C. Blicke, have long been accuſtomed to direct fumigated ſtockings, or under-waiſtcoats, to be worn; by which the complaints have been relieved, and the conſtitutions of the patients affected, without the trouble and unpleaſantneſs ariſing from the uſe of the common mercurial ointment. (See Abernethy's Surgical and Phyſiological Eſſays, part 3.)

Mr. Pearſon procured Lalonette's machine, and made a conſiderable number of experiments to determine the comparative advantages of this method and mercurial frictions. He found, that the gums became turgid and tender very quickly, and that the local appearances were ſooner removed, than by the other modes of introducing mercury into the ſyſtem; but that it ſoon brought on debility, a rapid and premature ſalivation, and, of courſe, the medicine could not be ſteadily continued. This gentleman concludes, that where checking the progreſs of the diſeaſe ſuddenly is an object of great moment, where the body is covered with venereal ulcers, or where the eruptions are large and numerous, ſo that there ſcarcely remains a ſurface large enough to abſorb the ointment, the vapour of mercury will be advantageous. But he thinks it extremely difficult thus to introduce a ſufficient quantity of mercury into the ſyſtem to ſecure the patient from a relapſe, and therefore by no means eligible as a general practice. The vapour of mercury, he ſays, is ſingularly efficacious when applied to venereal ulcers, fungi, and excreſcences; but this plan requires an equal quantity of mercury to be given in other ways, as if the local application itſelf were not a mercurial one. (Pearſon on Lues Venerea, p. 145, &c.)

For the purpoſe of fumigating ſores, the hydrargyrus ſulphuratus ruber is commonly uſed. Ulcers and excreſcences about the pudendum and anus in women are ſaid to be particularly benefited in this way; and in theſe caſes the fumes are moſt conveniently applied by placing a red-hot heater at the bottom of a night-ſtool pan, and after ſprinkling on it a few grains of the red ſulphurated quickſilver, placing the patient on the ſtool. On other occaſions, a ſmall apparatus, ſold at the ſhops, is uſed, which enables the ſurgeon to direct the fumes through a funnel againſt the ulcer in any ſituation.

Though mention has juſt been made of venereal excreſcences, it is very queſtionable, whether any are ever really of this nature. Many excreſcences and verrucæ about the anus, and parts of generation, diminiſh and are cured by a courſe of mercury. This is the only argument in favour of their being venereal; for, when tied, cut off, or made to fall off by ſtimulating them with pulv. fabinæ and ærugo æris, they are as effectually cured, as if mercury had been given. Cooper's Dictionary of Practical Surgery, art. *Mercury*.

FUMIGATOR, formed of *fumus*, ſmoke, an inſtrument uſed for injecting clyſters of the ſmoke of tobacco. Clyſters of this kind have been applied in the iliac paſſion, in the hernia incarcerata, and in other caſes of an obſtinate conſtipation, or obſtruction of the bowels; and as they are admirably adapted to excite the ſuſpended or extremely languid periſtaltic motion of the inteſtines, which are reckoned among the moſt irritable parts of the body, and are allowed to retain the vital influence longer than any other, they have been peculiarly ſerviceable in caſes of recovery from apparent death by drowning, &c. The inſtrument commonly uſed for the injection of theſe clyſters is formed with an iron or braſs capſula for containing a certain quantity of tobacco, to which capſula are faſtened two pipes; one of them made of bone, to be inſerted into the anus; and the other of ivory, in the ſhape of that end of the trumpet which is applied to the mouth; by means of which the ſmoke of the burning tobacco in the capſula is forced through the firſt pipe into the anus. The Dutch have made the bowl of this inſtrument large enough to contain three-fourths of an ounce of tobacco; it is conſtructed of wood, lined with braſs or tin, and covered by a top of wood lined in the ſame manner; the top is ſcrewed upon the other; the inſtrument is uſed by means of a wooden tube or blow-pipe, ſcrewed to the top, and adapted either to the mouth, or to a pair of bellows. The inſtrument uſed by the French is compoſed of a box reſembling the bowl of a pipe, covered by a lid, at the upper part of which is a hole or chimney, for giving air to the tobacco at pleaſure. From the ſide of this cover proceeds a tube, about four inches in length, incorporated with it, and adapted at the other extremity to the end of a flexible tube. At the lower part of this box is inſerted a kind of tubular handle, which admits the nozzle of a pair of bellows, faſtened to it by means of an iron pin paſſing tranſverſely through both. By this contrivance, when the tobacco is lighted, it is not neceſſary to touch the heated box; and the bellows ſerves as a handle by which to direct all the neceſſary movements: the whole inſtrument is made of copper.

Mr. Wriggleſworth, in conſequence of hints and obſervations communicated to him by Dr. Cogan, has conſtructed a fumigator, free from the inconveniences attending thoſe already mentioned. The bowl or body of this new inſtrument is made of caſt braſs, and is large enough to contain about an ounce and a half of tobacco. The pipe projecting from the lower part of it is bored out of a ſolid piece of braſs, and alſo thoſe to which each extremity of the leathern tube is affixed. The cover is likewiſe made of caſt braſs; from the upper extremity of which projects a neck about an inch and a half in length, the opening or bore of it being about half an inch in diameter. The cover is fixed to the box by means of two notches made on each ſide of a circular ridge or edge, admitting two ears, that project from the upper part of the box, which by a circular motion lock upon the brim.

The nozzle of the bellows is accurately adapted to the neck of the cover, and is about an inch and half or two inches long; the lower end of the nozzle is rounded and ſmooth, like the lower extremity of a glyſter-pipe, and perforated like a cullender, in order to prevent the aſhes of the tobacco from riſing into the bellows. The bellows are faſtened upon the cover or lid in a manner ſimilar to the preceding; an ear projects from the upper part of the neck, and is admitted into a notch, in a circular rim, upon the nozzle. The pipe projecting from the lower extremity of the bowl, locks into the croſs-pipe to which the leathern tube is affixed, in the manner of a bayonet. By this kind of faſtening the whole apparatus may be made ready in the ſpace of a minute, and forms one compact body, free from the hazard of falling in pieces, and thus interrupting the operation; and yet either part may be taken off, when the occaſion requires, with the utmoſt eaſe and expedition. The bowl is incloſed in a thick caſe of wood, removeable at pleaſure; which ſecures the hand from injury during the whole proceſs. The ſame ingenious artiſt has alſo conſtructed a machine ſo formed, as to contain the above deſcribed fumigator, with every requiſite for beginning an operation in the recovery of perſons apparently drowned, &c. ſuch as brandy, ſalt, ſpirit of ſal ammoniac, tinder-box, flint and ſteel, and cloths to rub the body. This machine is light and portable, being not much larger than a caſe of ſurgical inſtruments. Reports of the Humane Society, 1775, p. 82, &c. See DROWNING.

FUMING, in *Metallurgy*, the firſt calcination of the ores of metals, intended to diveſt them of their ſulphurs. See ROASTING.

FUMITORY, in *Botany*. See FUMARIA.

FUMOS, CAPE, in *Geography*, a cape on the coaſt of Africa, in the Indian ſea. N. lat 27° 30'. E. long. 29° 17'.

FUNAI, or FUGEO, a town of Japan, ſituated in a bay on the E. coaſt of the iſland of Ximo. N. lat. 33° 20'. E. long. 133° 20'.

FUNAMBULUS, among the Romans, was what we call a *rope-dancer*, and the Greeks, *ſchœnobates*.

The term is alſo uſed for ſuch as, letting themſelves down by a rope or cord, make their eſcape out of a city, or place beſieged, as is obſerved by Du-Cange.

Julius Capitolinus, and Horace, make mention of funambuli. Acron on Horace aſſures us, that it was the orator Meſſala who firſt introduced the word funambulus, in lieu of ſchœnobates, uſed by the Greeks. For the Greeks ſeem to have had ſome of theſe rope-dancers from the firſt inſtitution of their ſcenic games, which are ſaid to have been invented about the time of Icarius, father of Erigone; or of Dionyſias, ſurnamed Liber Pater, whom Theſeus firſt introduced into Athens.

At Rome, the funambuli firſt appeared under the conſulate of Sulpicius Pæticus and Licinius Stolo, who were the firſt introducers of the ſcenic repreſentations. It is added, that they were firſt exhibited in the iſland of the Tiber; and that the cenſors Meſſala and Caſſius afterwards promoted them to the theatre.

In the Floralia, or ludi Florales, held under Galba, there were funambulatory elephants, as we are informed by Suetonius. Nero alſo ſhewed the like, in honour of his mother Agrippina. Vopiſcus relates the ſame of the time of Carinus and Numerianus.

There was a funambulus, it ſeems, who performed at the time when the Hecyra of Terence was acted; and the poet complains, that the ſpectacle prevented the people from attending to his comedy: "Ita populus ſtudio ſtupidus in funambulo animum occupârat."

FUNARIA, in *Botany*, from *funis*, a cord, on account of the twiſted ſtructure, and very active hygrometrical properties, of the fruit-ſtalk, is a genus of Moſſes, founded by Hedwig on the *Mnium hygrometricum* of Linnæus, Hudſon, and others. It has an angular veil, a double fringe with oblique or twiſted teeth, and a very ſlightly prominent lid. This genus is admitted into the *Flora Britannica*, and two or three new ſpecies have recently been added to the original one, among which is *F. Muhlenbergii*, a native of Ireland as well as of America.

FUNCH, JOHN, in *Biography*, was born at Werden, near Nuremberg, in the year 1518: little is known of his early life, but that he diſcovered a great love of literature, and was admitted to the profeſſion of the miniſtry. He was choſen court preacher to Albert duke of Pruſſia, and having a turn for politics, he engaged in cabals unfavourable to the intereſts of the Poliſh nation. For this he was proſecuted in the name of the province, and condemned to be put to death as a diſturber of the public peace. He was beheaded at Konigſberg in 1566, in the forty-ninth year of his age. He was author of a ſyſtem of "Chronology," which went through ſeveral editions; of "Commentaries upon the Apocalypſe;" of "The life of Andrew Oſiander," his father-in-law; of "The life of Vitus Theodorus," &c. He is ſaid to have compoſed the following verſes on the morning of his execution:

"Diſce, meo exemplo, mandato munere fungi.
Et fuge, ceu peſtem, *την πολυπραγμοσυνην*."

That is, learn, from my unhappy fate, to attend to your own buſineſs, and avoid, as a plague, the deſire of meddling with too many things. Moreri. Bayle.

FUNCHAL, or FUNCHIALE, in *Geography*, a ſea-port town and capital of the iſland of Madeira, ſituated in a valley on the S. coaſt of the iſland: deriving its appellation from *funcho*, the Portugueſe name for fennel, which grows in great plenty upon the neighbouring rocks, and by the obſervation of Dr. Heberden lying in N. lat. 32° 33' 33" and W. long. 16° 49'. It is ſituated in the bottom of a bay, and though larger than the extent of the iſland ſeems to deſerve, is very ill built; the houſes of the principal inhabitants are large, thoſe of the common people are ſmall, the ſtreets are narrow, and very badly paved. The harbour is defended by ſeveral batteries and a caſtle. It contains ſix pariſhes, ſeveral chapels, and ſix convents, with ſeveral hoſpitals. The churches are loaded with ornaments, among which are many pictures, and images of favourite ſaints, but the pictures are in general wretchedly painted, and the ſaints are dreſſed in lace clothes. Some of the convents are in a better taſte, eſpecially that of the Franciſcans, which is plain, ſimple, and neat in the higheſt degree. The infirmary is a model, which might be adopted in other countries with great advantage. In this is a ſmall chapel, the whole lining of which, both ſides and cieling, is compoſed of human ſculls and thigh bones.

The Portugueſe, though numerous, do not conſtitute the bulk of the inhabitants; the Engliſh and French Roman Catholics, who live in the Portugueſe manner, are juſtly ſuppoſed to exceed the others in number and wealth; under theſe there is a large multitude of Mulatto and Negro freemen. The principal trade of the inhabitants conſiſts in wine and ſweatmeats. The tides at this place flow at the full and change of the moon north and ſouth; the ſpring tides riſe ſeven feet perpendicular, and the neap-tides four. The refreſhments which ſhips may obtain here are water, wine, fruit of ſeveral ſorts, onions in plenty, and ſome

ſweetmeats: freſh meat and poultry are not to be had without leave of the governor, and at a high price.

FUNCHEON, a river of the county of Cork, Ireland, which riſes in the Galtie mountains, and paſſing near the town of Kilworth, waters the beautiful ſeat of lord Mountcaſhel, and then joins the Black-water a few miles below Fermoy.

FUNCTION, the act of doing ſomething for which the agent was appointed, or to which he was obliged.

FUNCTION is alſo uſed figuratively in ſpeaking of the offices, duties, or occupations in which a perſon is engaged.

The actions of an ambaſſador muſt be diſtinguiſhed from his functions; the one regard his character, the other his perſon.

FUNCTION, in *Analyſis*. The function of any quantity, as x, is any algebraic expreſſion of calculation into which x enters, mixed with other quantities that have invariable values; thus $\frac{1}{1+x}$, $(1+x^n)$, $(1+x)^{\frac{1}{2}}$, $(1+bx)^m \log. x$, &c. are all expreſſions which may be called functions of x: x is here ſuppoſed to be a variable quantity, and the object of the theory of analytic functions is to inveſtigate rules and proceſſes for determining in what manner certain variations of the quantity x will affect the values of the expreſſions, which, like the above, are functions of x.

Though the theory of analytic functions is ſo comprehenſive as to embrace the whole doctrine of variable quantities, or magnitudes, of what nature ſoever, yet it is nothing more than a continuation or branch of common algebra. It requires no new hypotheſis, but derives all its rules from the nature of the ſymbolical language adopted in that ſcience, and from the ſignification which by convention has been given to various analytical expreſſions. In its application to the inveſtigation of problems, it is analogous to the differential or fluxional calculus, but free from the objection ſo often urged againſt thoſe methods. Principles derived from the doctrine of bodies in motion, when applied to the inveſtigation of ſimple analytical expreſſions, ſeem evidently very remote from the ſubject in queſtion, and from that circumſtance alone we might very reaſonably be induced to ſuſpect the exiſtence of ſome other more appropriate method.

Surely it cannot be neceſſary to have recourſe to mechanical principles to ſhew what is the product of $a+x$ multiplied by $a+x$ a certain number of times, yet this is continually done by writers on fluxions, when they attempt to demonſtrate the binomial theorem by proceſſes derived from the principles of motion. It may ſometimes however happen that we are guided in our path to the diſcovery of general principles, from reflecting on the circumſtances which take place in partial inſtances. This has been the caſe in the doctrine of fluxions. The relation between the time employed and the ſpace deſcribed by a body in motion has given riſe to our idea of velocity; and from conſiderations drawn from theſe particular variable quantities, ſome principles have been deviſed, which it appears are applicable to variable quantities in general; yet the more logical method would certainly have been, firſt to have eſtabliſhed the law of variable magnitudes generally, and then to have ſhewn their application to the particular caſe of a body in motion.

It was a celebrated mathematician of our own country, Landen, who firſt propoſed to treat the fluxionary calculus as a branch of common algebra, but the method which he propoſes to ſubſtitute for it, is not only ſomewhat objectionable in its principle, but very incommodious in its practical application.

In the year 1772, M. Lagrange, in the Memoirs of the Academy of Berlin, firſt undertook to explain in what manner the fluxionary or differential calculus was included in the theory of the expanſion, in a ſeries of analytic functions. This celebrated work, entitled "Théorie des Fonctions Analytiques," appeared in 1796; it has ſince been illuſtrated and extended in another publication, "Leçons ſur le Calcul des Fonctions," 1806.

In theſe works the reader will find the whole theory of variable quantities completely developed, and applied to a great variety of important inveſtigations. Though we have no book in our own language which treats this ſubject on ſo extenſive a ſcale, yet the theory and principles on which the whole of this calculus depends, have been moſt ably explained by R. Woodhouſe, eſq. F.R.S. of Cambridge, in his "Principles of Analytical Calculation," a work which, for clearneſs, elegance, and perſpicuity, will probably for a long time remain unrivalled, and can never be excelled.

It is from theſe publications, and particularly the laſt, that the preſent abſtract is profeſſedly compoſed. But to enable the reader to comprehend the object propoſed, we ſhall endeavour to illuſtrate it by ſome very eaſy and ſimple examples.

Suppoſe $y = ax$, x being a variable quantity, y is then ſaid to be a function of x, ſince it depends on x for its value. If x aſſumes a new value, and becomes $x+\Delta x$ (Δx expreſſing the increment of x) y will require a new value, expreſſed in like manner by $y+\Delta y$. In this caſe we ſee immediately how the propoſed alteration in the value of x will affect the value of y; for ſubſtitute $x+\Delta x$ for x in the expreſſion ax, and it becomes $ax + a.\Delta x$. Therefore

$$y + \Delta y = ax + a.\Delta x;$$
$$\text{and} \quad \Delta y = a.\Delta x.$$

It appears, therefore, that in the above equation, $y = ax$, if any variation is made in the value of x, the correſponding alteration in the value of y is a times as great.

Again, ſuppoſe $y = x^3$;
let x become $x+\Delta x$; then

$$y + \Delta y = x^3 + 3x^2.\Delta x + 3x.(\Delta x)^2 + (\Delta x)^3$$
$$\text{and } \Delta y = 3x^2.\Delta x + 3x.(\Delta x)^2 + (\Delta x)^3.$$

In the firſt of the above examples, Δy, or the new value of y, conſiſts of a ſingle term, namely, Δx with a co-efficient. In the ſecond example, Δy conſiſts of a ſeries of ſeveral terms, the firſt of which is Δx, with a certain co-efficient; the others contain regular aſcending powers of Δx, Δx^2, Δx^3, with their reſpective co-efficients.

It will be ſeen that it is under this form that Δy, or the new value of φx or y, may be moſt commonly obtained.

The object of reſearch is to find one or more terms, and ſometimes the whole of this ſeries, from the given relation between φx and x, and ſometimes the reverſe; or to find from one or more of theſe terms the original relation that ſubſiſted between φx and x. Theſe two methods, namely, the direct and reverſe, are analogous to the finding fluxions and fluents in the uſual fluxionary calculus.

If y be any function of $x = \varphi x$, and its new value $y + \Delta y$ be obtained in the form of a ſeries aſcending according to the powers of Δx, then the firſt term of that ſeries, conſiſting of Δx and its co-efficient, is called the firſt derived function, or the differential of the variable quantity: it is the ſame as the fluxion of that quantity, but we do not obtain it in conſequence of any particular hypotheſis. The differential is only known to be the firſt term in conſequence of a previous definition, entirely arbitrary. The fluxion of a quantity is, on the contrary, obtained in conſequence of a particular theory; therefore, in whatever proceſs it is applied,

that whole proceſs becomes burthened with all the imperfections to which that original theory is liable. All this will be more diſtinctly ſeen hereafter; what is ſaid at preſent is only to introduce the ſubject, by appriſing the reader of the object of the ſcience.

The notation we ſhall adopt is the ſame as that uſed by Mr. Woodhouſe, after M. D'Arbogaſt. It differs materially from that of Lagrange.

Δ, denotes the entire difference,
d, the differential,
D, the differential co-efficient,
∂, the variation.

Thus, if $\overline{a+x}^m$ be expanded, the co-efficient of the term involving x is always found by multiplying the index (m) of the firſt term a^m, into that term, its index being diminiſhed by unity: D, therefore, denotes this operation; hence D a^m ſignifies $m a^{m-1}$, D a^{-m} ſignifies $-m a^{-m-1}$, &c.

D D D a^m, or $D^3 a^m$, denotes that three ſimilar operations are to be made, the firſt on a^m, the ſecond on the power of a that reſults after the firſt operation, the third on the power of a, which remains after the ſecond; hence $D^3 a^m$ ſignifies $m D^2 a^{m-1}$, or $m \cdot \overline{m-1} \cdot D\, a^{m-2}$, or $m \cdot \overline{m-1} \cdot \overline{m-2} \cdot a^{m-3}$.

Similarly, D D.....Da^m (n D's and $n \angle m$) ſignifies $m (m-1) (m-2) \ldots\ldots (m-n+1) a^{m-n}$.

Or, if D D D.....D (n) be abridgedly repreſented by D^n, $D^n a^m$ ſignifies $m (m-1) (m-2) \ldots\ldots\ldots\ldots (m-n+1) a^{m-n}$,

$D^2 a^2$, $3 \cdot 2 \cdot 1\, a^0$; $D^3 a^4$, $4 \cdot 3 \cdot 2\, a$;

$D^3 1^m$, $m \cdot (m-1) (m-2)\, 1^{m-3}$;

$D^2 1^{-\frac{1}{2}}$, $-\frac{1}{2} \cdot \frac{-3}{2} 1^{-\frac{5}{2}}$, or $\frac{3}{4} 1^{-\frac{5}{2}}$, or $\frac{3}{4}$;

$D^3 1^{\frac{1}{3}}$, $\frac{1}{3} \cdot \frac{-2}{3} \cdot \frac{-5}{3} 1^{-\frac{8}{3}}$, or $\frac{10}{27} 1^{-\frac{8}{3}}$ or $\frac{10}{27}$;

$D^2 a^{-m}$, $-m \cdot -m-1 \cdot a^{-m-2}$, or $m \cdot (m+1) \cdot a^{-(m+2)}$.

The propoſition aſſumed by Lagrange, and which forms the baſis of his whole work, is this, that if φx be any function whatever of a variable quantity x, and x changes its value, and becomes $x+i$, then the $\varphi (x+i)$ may be repreſented or reſolved into a ſeries of this form, $\varphi x + P i + Q i^2 + R i^3$, &c. in which the co-efficients of the powers of i are new functions of x, derived from the primitive function x independent of i, and moreover, that every co-efficient is derived from the preceding one, in the ſame manner as the firſt is derived from the original function.

Could ſuch a general propoſition as this be ſatisfactorily demonſtrated, it would, no doubt, lead us at once a great way in the ſcience. The binomial theorem, and other ſeries of frequent occurrence, would need no ſeparate inveſtigation, but would follow as particular caſes of a general rule.

But Mr. Woodhouſe, in the work alluded to, has clearly ſhewn that this aſſumption of Lagrange is much too general, and that no ſuch theory of ſeries can be eſtabliſhed which ſhall preclude the neceſſity of any farther examination of particular forms. Now the function of x or φx comprehends, under its general ſignification, a variety of combinations, ſuch as x^m, a^x, log. x, ſin. x, coſ. x, &c. It ſeems, therefore, eſſentially neceſſary in an elementary treatiſe to conſider theſe forms, and to ſhew in what manner, and with what reſtrictions, they may be included under any general expreſſion. The well-known binomial theorem we ſhall take for granted, but not as a propoſition derived from any abſtract principle, but as the reſult of inveſtigation depending in great meaſure on inſpection and trial. (See Manning's Algebra.)

Thoſe authors who endeavour to give it a higher origin, as capable of being deduced from principles of motion, as in many treatiſes on fluxions, ſeem to have been led into the error of ſuppoſing known what actually they were in ſearch of. Inſtances are to be found where the elementary rules of the ſcience of fluxions are founded on the law of the binomial theorem, and that theorem afterwards demonſtrated by the application of thoſe very rules which could not themſelves have been deviſed without the previous knowledge of the theorem to be inveſtigated.

But, however this may be, let us at preſent take the truth of this theorem for granted, and proceed to a farther inveſtigation of the ſubject.

Note.—For the purpoſe of a more commodious notation, D^n_c repreſents $\frac{D^n}{1 \cdot 2 \cdot 3 \ldots n}$; $\frac{D^2}{c} = \frac{D^2}{1 \cdot 2}$; $\frac{D^3}{c} = \frac{D^3}{1 \cdot 2 \cdot 3}$ &c.

$\overline{a+x}^m$ being then aſſumed equal $a^m + \frac{D}{c} a^m x + \frac{D^2}{c} a^{m-2} x^2 + \frac{D^3}{c} x^3$, &c. the next expreſſion to be conſidered is $\varphi x = a^x$.

Now, in the expreſſion a^x there is nothing indicative of any operation that can be performed in a manner analogous to that of $\overline{a+x}^n$, ſome artifice muſt be deviſed to change its form for that purpoſe; one of the moſt ſimple is, to make $1+b=a$, or a^x may be put under this form, $a^x = (1+(a-1))^x$: then by the preceding theorem, where $a=1$, $x=a-1$, $m=x$, $a^x = (1+(a-1))^x = 1 + x (a-1) + \frac{x \cdot (x-1)}{1 \cdot 2} (a-1)^2 + x \cdot \frac{(x-1) \cdot (x-2)}{1 \cdot 2 \cdot 3} (a-1)^3$, &c. &c.

$= 1 + x ((a-1) - \frac{1}{2} (a-1)^2 + \frac{1}{3} (a-1)^3 - \frac{1}{4} (a-1)^4 \ldots\ldots\ldots\ldots$ or $A x + \frac{x^2}{1 \cdot 2} ((a-1)^2 - (a-1)^3 + (a-1)^4 \ldots\ldots A_{,} x$

$= 1 + A x + A_{,} x^2 + A_{,,} x^3$;

in which ſeries the quantities A, A, $A_{,}$, $A_{,,}$, are conſtant co-efficients, but unknown. To determine the law of their connexion or dependance on each other, increaſe x by the indeterminate quantity z;

then $a^{x+z} = 1 + A (x+z) + A (x+z)^2 \ldots A_{n-1} (x+z)^n$;

or expanding the powers of $x+z$, ſtopping at the two firſt terms

$a^{x+z} = 1 + A (x+z) + A_{,} (x^2 + 2xz + \&c.) + A_{,,} (x^3 + 3x^2 z + \&c.)$

$A n-1 (x^n + n x^{n-1} z + \&c.) + A (x^{n+1} + (n+1) x^n z + \&c.)$

Again, $a^{x+z} = a^x = (1 + A x + A_{,} x^2 \ldots A_{n-1} x^n + \&c.)$

$\times (1 + A z + A_{,} z^2 \ldots A^{n-1} z^n + \&c.)$

$= 1 + A (x+z) + A_{,} x^2 + A_{,,} z \ldots\ldots + A^{n-1} x^2$

$+ A^2 xz + A_{,} A \cdot x^2 z \ldots + A^{n-1} \cdot A x^{n-1} z$.

Compare the correſponding terms in the two expanſions, and

$2 A_{,} = A^2$, and $A_{,} = \frac{A^2}{2}$, $3 A_{,,} = A A_{,} = \frac{A^3}{2}$, and $A_{,,,} = \frac{A^3}{1 \cdot 2 \cdot 3}$ $n A_{n-1} = A_{n-2} A$ or $A_{n-1} = \frac{A n-2 A}{n} = \frac{A^n}{1 \cdot 2 \cdot 3 \cdot 4}$

Hence, $a^x = 1 + A x + \frac{A^2 \cdot x^2}{1 \cdot 2} + \frac{A^3 x^3}{1 \cdot 2 \cdot 3} + \frac{A^4 x^4}{1 \cdot 2 \cdot 3 \cdot 4}$

If $x = 1$

$a =$

$$a = 1 + A + \frac{A^2}{1.2} + \frac{A^3}{1.2.3} + \&c.$$

If $x = \frac{1}{A}$

$a^{\frac{1}{A}} = 1 + 1 + \frac{1}{1.2} + \frac{1}{1.2.3} + \&c. = 2.718281824$,

and when $A = 1 . a = 1 + 1 + \frac{1}{1.2} + \frac{1}{1.2.3} =$ 2.71828 1824 $= e$, suppoſe therefore $a^{\frac{1}{A}} = e$, and $a = e^{A}$,

then $e^x = 1 + x + \frac{x^2}{1.2} + \frac{x^3}{1.2.3} + \frac{x^4}{1.2.3.4}$;

x is here ſuppoſed variable; let the difference between it and its ſucceſſive value be expreſſed by the ſymbol Δx.....

then $e^{\Delta x} = 1 + \Delta x + \frac{(\Delta x)^2}{1.2} + \frac{(\Delta x)^3}{1.2.3} + \&c.$

$e^{x+\Delta x} = e^x + e^x \Delta x + \frac{e^x (\Delta x)^2}{1.2} + \frac{e^x (\Delta x)^3}{1.2.3} + \&c.$

Since $e^{-x} = 1 - x + \frac{x^2}{1.2} - \frac{x^3}{1.2.3}$ &c.

$e^x + e^{-x} = 2 + \frac{2x^2}{1.2} + \frac{2x^4}{1.2.3.4}$;

or $\frac{e^x + e^{-x}}{2} = 1 + \frac{x^2}{1.2} + \frac{x^4}{1.2.3.4} + \frac{x^6}{1.2.3.4.5.6} + \&c.$

and $\frac{e^x - e^{-x}}{2} = x + \frac{x^3}{1.2.3} + \frac{x^5}{1.2.3.4.5} + \frac{x^7}{1.2.3.4.5.6.7}$ + &c.

Again $e^{x+\Delta x} + e^{-(x+\Delta x)} = (e^x - e^{-x}) + (e^x - e^{-x}) \Delta x + (e^x + e^{-x}) . \frac{(\Delta x)^2}{1.2} + \&c.$

And $e^{x+\Delta x} - e^{-(x+\Delta x)} = (e^x - e^{-x}) + (e^x + e^{-x}) \Delta x + (e^x - e^{-x}) . \frac{(\Delta x)^2}{1.2}$.

In the form for e^x for x ſubſtitute $\pm x\sqrt{-1}$, then the ſymbol $e^{x\sqrt{-1}}$ repreſents $1 + x\sqrt{-1} - \frac{x^2}{1.2} - \frac{x^3\sqrt{-1}}{1.2.3}$ &c

and $e^{-x\sqrt{-1}}$ repreſents $1 - x\sqrt{-1} - \frac{x^2}{1.2} + \frac{x^3\sqrt{-1}}{1.2.3}$ − &c.

and conſequently $\frac{e^{x\sqrt{-1}} + e^{-x\sqrt{-1}}}{2}$ is the ſymbol for $1 - \frac{x^2}{1.2} + \frac{x^4}{1.2.3.4}$ − &c.

and $\frac{e^{x\sqrt{-1}} - e^{-x\sqrt{-1}}}{2\sqrt{-1}}$ is the ſymbol for $x - \frac{x^3}{1.2.3} + \frac{x^5}{1.2.3.4.5}$ − &c.

again $e^{x\sqrt{-1}} \times e^{\Delta x\sqrt{-1}} = e^{x\sqrt{-1}} . \Delta x\sqrt{-1} - \frac{e^{x\sqrt{-1}}(\Delta x)^2}{1.2}$ − &c.

$e^{-x\sqrt{-1}} \times e^{-\Delta x\sqrt{-1}} = e^{-x\sqrt{-1}} - e^{-x\sqrt{-1}} . \Delta x\sqrt{-1} - \frac{e^{-x\sqrt{-1}}(\Delta x)^2}{1.2} + \&c.$

$\therefore \frac{e^{(x+\Delta x)\sqrt{-1}} + e^{-(x+\Delta x)\sqrt{-1}}}{2} = \frac{e^{x\sqrt{-1}} + e^{-x\sqrt{-1}}}{2} + \frac{e^{x\sqrt{-1}} - e^{-x\sqrt{-1}}}{2} . \Delta x\sqrt{-1} - \frac{e^{x\sqrt{-1}} + e^{-x\sqrt{-1}}}{1.2} (\Delta x) + \&c.$

The form for a^x being determined, ſuppoſe it were required to determine X in terms of x; in this equation $x = a^X$. Since $x = a^X$, $x^z = a^{Xz}$ (z being an independent arbitrary quantity,) conſequently from the laſt article, if $(x-1) - \frac{1}{2}(x-1)^2 + \frac{1}{3}(x-1)^3 - \&c.$ be put $= V$;

then $1 + Vz + \frac{(Vz)^2}{1.2} + \frac{(Vz)^3}{1.2.3} + \&c.$

$= 1 + AXz + \frac{(AXz)^2}{1.2} + \frac{(AXz)^3}{1.2.3}$, &c. Hence comparing the co-efficients affected with the ſame powers of z

$V = AX$ or $X = \frac{V}{A} = \frac{(x-1) - \frac{1}{2}(x-1)^2 + \frac{1}{3}(x-1)^3 - \&c.}{A}$

&c.

$= \frac{(x-1) - \frac{1}{2}(x-1)^2 + \frac{1}{3}(x-1)^3 - \&c.}{(a-1) - \frac{1}{2}(a-1)^2 + \frac{1}{3}(a-1)^3 - \&c.}$

Hence, if equations, as $x = a^X$, $1 + x = a^X$, &c. be thus denoted,

$x = a^{\varphi x}$, $1 + x = a^{\varphi(1+x)}$, we have

$$\varphi(1+x) = \frac{x - \frac{x^2}{2} + \frac{x^3}{3} - \&c.}{A}$$

In like manner $\varphi\left(1 + \frac{\Delta x}{x}\right)$

$= \frac{\frac{\Delta x}{x} - \frac{1}{2}\left(\frac{\Delta x}{x}\right)^3 + \frac{1}{3}\left(\frac{\Delta x}{x}\right)^3 - \&c.}{A}$

And ſince $x + \Delta x = x + \left(1 + \frac{\Delta x}{x}\right)$, $a^{\varphi(x+\Delta x)} = a^{\varphi x} \times a^{\varphi(1+\Delta x)}$.

Therefore $\varphi(x + \Delta x) = \varphi x + \varphi\left(1 + \frac{\Delta x}{x}\right)$,

or $\varphi(x + \Delta x) = \varphi x + \frac{\frac{\Delta x}{x} - \frac{1}{2}\left(\frac{\Delta x}{x}\right)^2 + \frac{1}{3}\left(\frac{\Delta x}{x}\right)^3 - }{A}$

&c.

If $x = a^{\varphi x}$, $x^{\frac{1}{2}} = a^{\frac{\varphi x}{2}}$, $x^{\frac{1}{3}} = a^{\frac{\varphi x}{3}}$, &c.

and generally $x^{\frac{1}{m}} = a^{\frac{\varphi x}{m}}$; then

$\varphi x = \frac{2}{A}\left(\left(x^{\frac{1}{2}} - 1\right) - \frac{1}{2}\left(x^{\frac{1}{2}} - 1\right)^2 + \frac{1}{3}\left(x^{\frac{1}{2}} - 1\right)^3 - \&c.\right)$

or $= \frac{3}{A}\left(\left(x^{\frac{1}{3}} - 1\right) - \frac{1}{2}\left(x^{\frac{1}{3}} - 1\right)^2 + \frac{1}{3}\left(x^{\frac{1}{3}} - 1\right)^3 - \&c.\right)$

or generally $= \frac{m}{A}\left(\left(x^{\frac{1}{m}} - 1\right) - \frac{1}{2}\left(x^{\frac{1}{m}} - 1\right)^2 + \frac{1}{3}\left(x^{\frac{1}{m}} - 1\right)^3 - \&c.\right)$

In the equation $x = a^X$, or $= a^{\varphi x}$, X or φx is called the logarithm of x, and a the baſe; if the value of a be ſuch that A or $(a-1) - \frac{1}{2}(a-1)^2 + \frac{1}{3}(a-1)^3 - \&c. = 1$, repreſenting this value of a by e $\left(= 1 + 1 + \frac{1}{1.2} + \frac{1}{1.2.3}\right.$

and

and = 2.7182818284, &c.); then in the equation $x = e^x$ or $e^{\phi x}$, X or ϕx is commonly called the hyperbolic logarithm, becauſe it can be repreſented by the area of an equilateral hyperbola between its aſymptotes: the name, however, is improperly given, ſince the connection between the theories of curve lines and logarithms is merely arbitrary and accidental.

It has appeared that

$$(x + \Delta x)^m = x^m + m x^{m-1} . \Delta x + \frac{m . (m-1)}{2} , x^{m-2} (\Delta x)^2 + \&c.$$
$$= x^m + D x^m . \Delta x + \overset{D^2}{c} x^m (\Delta x)^2 + \&c.$$

Likewiſe that $a^{x+\Delta x} = a^x . A . \Delta x + \frac{a^x . A^2 (\Delta x)^2}{1 . 2}$, &c.

$$e^{x+\Delta x} = e^x + e^x \Delta x + \frac{e^x (\Delta x)^2}{1 . 2} + \&c.$$

and that in the equations $x + \Delta x = a^{L.(x+\Delta x)}$, $x + \Delta x = e^{l(x+\Delta x)}$;

$$L . (x + \Delta x) = L . x + \frac{1}{A} . \left(\frac{\Delta x}{x}\right) - \tfrac{1}{2} \left(\frac{\Delta x}{x}\right) + \tfrac{1}{3} \left(\frac{\Delta x}{x}\right)^3 - \&c.;)$$

$$l (x + \Delta x) = l . x . + \frac{\Delta x}{x} - \tfrac{1}{2} \left(\frac{\Delta x}{x}\right)^2 + \tfrac{1}{3} \left(\frac{\Delta x}{x}\right)^3 - \&c.$$

In the above expreſſions L . x denotes the common, and $l . x$ the Napierean or hyperbolic logarithm of x.

Of the expanſions of the forms x^m, a^x, e^x, $l . x$, when x is increaſed to $(x + \Delta x)$, it appears then, that there are certain common properties which can be predicated, and it becomes an object of analytic concern to deſignate theſe expreſſions x^m, e^x, &c. by a common ſymbol and name, and to comprehend their expanſions under a general formula. The advantage of this generalization is ſufficiently obvious (if it can be effected,) ſince it will enable us to announce generally and conciſely what otherwiſe we muſt announce tediouſly, by enumerating particular caſes.

The expreſſions x^m, a^x, $l . x$, are called functions of x, and are thus ſymbolically repreſented by F x, ϕx, $f x$, or $\downarrow x$, &c; and conſequently F $(x + \Delta x)$ or $\phi (x + \Delta x)$ or $f (x + \Delta x)$, $\downarrow (x + \Delta x)$, &c. mean either $(x + \Delta x)^m$, $a^{(x+\Delta x)}$, or $l (x + \Delta x)$.

Now the ſymbol D has hitherto only denoted that operation by which the co-efficient of the ſecond term in the expanſion of $(a + x)^m$ or $(x + \Delta x)^m$ is formed. Let it now be made to denote the operation made on x^m, a^x, $l . x$, &c. by which the co-efficient of the ſecond term, in the expanſions of $(x + \Delta x)^m$ $(a^{x+\Delta x})$, L . $(x + \Delta x)$ $(x + \Delta x = a^{L.(x+\Delta x)})$ is formed then under this ſignification; its former one will be comprehended, but it will no longer denote a ſimilar operation, as when reſtricted to expreſſions ſuch as x^m; D, however, when applied to ϕx, generally repreſents the ſecond term of the ſeries that ariſes from expanding ϕx, when for x we ſubſtitute its new value $x + \Delta x$; and that ſecond term can always be known, ſince all the expreſſions which $\phi (x + \Delta x)$ is made generally to repreſent, have been previouſly expanded.

Thus, $D x^m = m x^{m-1}$,

$D a^x = A a^x$, $D e^x = e^x$

$$D L . x = \frac{1}{A x} \quad D . l . x = \frac{1}{x}.$$

Hence D D x^m or $D^2 x^m$ denotes $m . (m-1) x^{m-2}$,
D D a^x or $D^2 a^x$ denotes D $(A a^x)$ or $A^2 a^x$,
D D D a^x or $D^3 a^x$ denotes $A^3 a^x$.

Again, D D $l . x$ or $D^2 l . x$ denotes $D \frac{1}{x}$ or $-\frac{1}{x^2}$,

D D D or $D^3 . l . x$ denotes D $(D^2 l . x)$ or $D \left(\frac{1}{x^2}\right)$ or $\frac{2}{x^3}$.

In like manner $D^4 l . x$ denotes D $(D^3 l . x)$ or $-\frac{2 . 3}{x^4}$.

Hence, ſince

$$(x + \Delta x)^m = x^m + m x^{m-1} \Delta x + \&c.$$
$$a^{x+\Delta x} = a^x + A a^x . \Delta x + \frac{A^2 a^x (\Delta x)^2}{1 . 2} + \&c.$$
$$L . (x + \Delta x) = L . x + \frac{\Delta x}{A x} + \frac{(\Delta x)^2}{2 . A . x^2} + \&c.$$
$$\text{and } l (x + \Delta x) = l . x + \frac{\Delta x}{x} - \tfrac{1}{2} \left(\frac{\Delta x}{x}\right)^2 + \&c.$$

It appears that all theſe forms may be comprehended under the following:

$$\phi (x + \Delta x) = \phi x + D \phi x . \Delta x + \overset{D^2}{c} \phi x (\Delta x)^2 + \&c.$$
$$\text{or} = \phi x + D \phi x . \Delta x + \frac{D \phi x (\Delta x)^2}{1 . 2} + \&c.$$

which agrees with the theorem known by the name of Taylor's theorem, and given by that learned mathematician in his "Methodus Incrementorum," wherein he ſays that z flowing uniformly and becoming $z + v$, x becomes

$$x + \dot{x} . \frac{v}{1} \dot{z} + \ddot{x} . \frac{v^2}{1 . 2} \dot{z}^2 + \dddot{x} . \frac{v^3}{1 . 2 . 3} \dot{z}^3 + \&c.$$

The co-efficients of the ſecond, third, &c. terms, are repreſented by $D \phi x$, $\overset{D^2}{c} \phi x$, $\overset{D^3}{c} \phi x$, &c.; and when ϕx is of the form $l . x$, $(x = e^{l . x})$ then the firſt term is $l . x$, and the co-efficient of the ſecond is $\frac{1}{x}$; but $-\frac{1}{x^2}$, the co-efficient of the third term, is not formed from $\frac{1}{x}$ as $\frac{1}{x}$ is from $l . x$.

When $D \phi x$, $D^2 \phi x$, &c. are ſaid to be derived from each other by the ſame law, it ſhould always be previouſly defined, that by the ſame law is meant that which orders the ſecond term of the ſeries to be taken when the function of x, whatever it is, has been expanded after ſubſtituting $x + \Delta x$ for x.

Since $a^{\pm (x+\Delta x)}$ or $e^{\pm (x+\Delta x)}$ will likewiſe be included under the form $\phi (x + \Delta x) = \phi x + D \phi x . \Delta x + \overset{D^2}{c} \phi x (\Delta x)^2 + \&c.$ it is clear that if $\phi (x)$ be made to repreſent $e^x \pm e^{-x}$, that $e^{x+\Delta x} \pm e^{-(x+\Delta x)}$ will likewiſe be included under the above form $\phi (x + \Delta x)$, and its expanſion likewiſe under the ſame form as that of $\phi (x + \Delta x)$.

Again, if the ſymbol $\sqrt{-1}$ be employed, $e^{(\pm (x+\Delta x)\sqrt{-1}}$ may be included under the form $\phi (x + \Delta x = \phi x + D \phi x . \Delta x + \overset{D^2}{c} \phi x . (\Delta x)$, and conſequently if ϕx be made to repreſent $e^{x\sqrt{-1}} \pm e^{x-\sqrt{-1}}$; then $e^{(x\Delta+x)\sqrt{-1}} \pm e^{-(x+\Delta x)\sqrt{-1}}$ will be included under the form $\phi (x + \Delta x) = \phi x + D \phi x . \Delta x + \overset{D^2}{c} \phi x . (\Delta x)^2 + \&c.$

The ſymbols $2^{-1} (e^{x\sqrt{-1}} + e^{-x\sqrt{-1}})$; $(2\sqrt{-1})^{-1} (e^{x\sqrt{-1}} - e^{-x\sqrt{-1}})$ repreſent the coſine and ſine of an arc x, whoſe radius is unity, and conſequently with reference to their

their analytica repreſentation, the expreſſions cof. $(x + \Delta x)$, ſin. $(x + \Delta x)$ expanded may be ſaid to be included under the form $\varphi(x + \Delta x) = \varphi x + D\varphi x(\Delta x . + \frac{D^2}{c} \varphi x (\Delta x)^2 +$ &c. But ſtrictly there is no more reaſon for conſidering ſin. x cof. x as a ſimple analytical function of x diſtinct from e^x, than for conſidering $e^x \pm e^{-x}$, or generally $e^{\alpha x} + e^{\beta x} + e^{\gamma x}$, &c. ($\alpha, \beta, \gamma$, &c. being roots of $x^n \pm 1 = 0$) as functions of x diſtinct from e^x.

On the nature of the above analytical expreſſions for the ſine and coſine of an arc x, the reader is referred to a very learned paper in the Tranſactions of 1802 by Mr. Woodhouſe, and likewiſe to the Treatiſe of Trigonometry by Le Gendre, p. 354. Since this article was written Mr. Woodhouſe has publiſhed a Treatiſe on Trigonometry, to which the reader is referred.

The caſes which Mr. Woodhouſe next conſiders in his principles of analytical calculation are thoſe of fractions, whoſe numerators and denominators under particular circumſtances vaniſh. Let us take a ſimple caſe, that of $\frac{x^2 - a^2}{x - a}$; the ſignification of this expreſſion is, that $x^2 - a^2$ is to be divided by $x - a$; the reſult of that diviſion is $x + a$, or putting $x = a$, $a + a$, or $2a$. The reſult, however, is no direct and natural conſequence from the principles of calculation. To the queſtion, what does $\frac{x^2 - a^2}{x - a}$ become, when $x = a$; the obvious and logical anſwer is $\frac{a^2 - a^2}{a - a}$. And what would be the method of ſhewing that this value $\frac{a^2 - a^2}{a - a}$ was wrongly aſſigned? This, I apprehend; $x^2 - a^2 = (x - a)(x + a)$, $\therefore \frac{x^2 - a^2}{x - a} = \frac{(x - a)(x + a)}{(x - a)} = x + a = (x = a)$, $2a$; but herein is a manifeſt fallacy; $x^2 - a^2$ is not *generally* $= (x - a)(x + a)$: for inſtance, the particular caſe of $x = a$ is to be excluded; the proof eſſentially demanding this circumſtance, to wit, that $x - a$ be a quantity, or that x be greater than a;

By the inſtances ſubjoined, it will more fully appear, that the values of vaniſhing fractions are arbitrarily obtained, that is, obtained by extending a rule, and obſerving a certain order in the proceſs of calculation.

Suppoſe the fraction $\frac{\sqrt{x} - \sqrt{a} + \sqrt{(x - a)}}{\sqrt{(x^2 - a^2)}}$; for x, put $a + (x - a)$, then,

$$(a + x - a)^{\frac{1}{2}} = a^{\frac{1}{2}} + \frac{(x - a)}{2a^{\frac{1}{2}}} - \frac{(x - a)^2}{8a^{\frac{3}{2}}} + \&c.$$

$$\therefore \text{fraction} = \frac{(x - a)^{\frac{1}{2}} + \frac{(x - a)}{2a^{\frac{1}{2}}} - \frac{(x - a)^2}{8a^{\frac{3}{2}}} + \&c.}{(x^2 - a^2)^{\frac{1}{2}}}$$

$$= \frac{1 + \frac{1}{2}\left(\frac{x - a}{a}\right)^{\frac{1}{2}} - \&c.}{(x + a)^{\frac{1}{2}}}$$; in this part of the operation put $x = a$, and the expreſſion is reduced to $\frac{1}{(2a)^{\frac{1}{2}}}$.

This reſult is the ſame as what the rules derived from the differential calculus give: and that the reſult is obtained arbitrarily, by artifice, and by obſerving in the proceſs, an order not indicated in the expreſſion, appears ſimply thus; inſtead of putting $a + (x - a)$ for x, put $(x - a) + a$, and $\sqrt{x}$ becomes $(x - a)^{\frac{1}{2}} + \frac{a}{2(x - a)^{\frac{1}{2}}} -$ &c. by which method we could arrive at no finite concluſion, ſince putting $x = a$, the co-efficients of the terms of $(x - a + a)^{\frac{1}{2}}$ expanded, would be infinite: yet, without a particular purpoſe in view, the latter ſeries is as true as the former; and, inſtead of x is ſubſtituted not $(x - a) + a$, but $a + (x - a)$, for the ſame reaſon, as 9 would be put $(8 + 1)$, and not $(1 + 8)$, if it were required to compute $9\frac{1}{2}$ by the binomial theorem.

Let now the fraction (F) be $\frac{(2r^3 x - x^4)^{\frac{1}{2}} - (r x^3)^{\frac{1}{2}}}{r - (r x)^{\frac{1}{2}}}$ which is the inſtance given by Bernouilli, and ſubſequently by Landen in his Reſidual Analyſis; the value of the fraction (F) is required when $x = r$;

$$\text{now } F = \frac{\left((r^3 x + x(r^3 - x^3)\right)^{\frac{1}{2}} - (r x^3)^{\frac{1}{2}}}{r^{\frac{1}{2}}(r^{\frac{1}{2}} - x^{\frac{1}{2}})}$$

$$= \frac{(r^3 x)^{\frac{1}{2}} + \frac{x \cdot (r^3 - x^3)}{2(r^3 x)^{\frac{1}{2}}} + A(r^3 - x^3)^2 + \&c. - (r x^3)^{\frac{1}{2}}}{r^{\frac{1}{2}}(r^{\frac{1}{2}} - x^{\frac{1}{2}})}$$

(A the co-efficient of the third term)

$$= \frac{(r x)^{\frac{1}{2}} \times (r - x) + \frac{x(r^3 - x^3)}{2(r^3 x)^{\frac{1}{2}}} + A(r^3 - x^3)^2 + \&c.}{r^{\frac{1}{2}}(r^{\frac{1}{2}} - x^{\frac{1}{2}})}$$

$$= \frac{(r x)^{\frac{1}{2}} \cdot (r^{\frac{1}{2}} + x^{\frac{1}{2}}) + \frac{x^{\frac{1}{2}}}{2 r r^{\frac{1}{2}}}(r^2 + r x + x^2) \cdot (r^{\frac{1}{2}} + x^{\frac{1}{2}}) + A \cdot (r^3 - x^3) \times \&c. + \&c.}{r^{\frac{1}{2}}}$$

when $x = r$, $= r^{\frac{1}{2}}(r^{\frac{1}{2}} + r^{\frac{1}{2}}) + \frac{1}{2 r r^{\frac{1}{2}}}(r^2 + r^2 + r^2)(r^{\frac{1}{2}} + r^{\frac{1}{2}}) = 2r + \frac{3r \times 2r}{2r} = 5r.$

Again, let the fraction (F) be $\frac{(2a^2 + 2x^2)^{\frac{1}{2}} - 2a^{\frac{2}{3}} x^{\frac{1}{3}}}{x - a}$, an inſtance given by Euler; the value of this fraction is required, when $x = a$;

$$\text{now } F = \frac{2^{\frac{1}{2}}\left(2x^2 - (x^2 - a^2)\right)^{\frac{1}{2}} - 2a^{\frac{2}{3}} x^{\frac{1}{3}}}{x - a}$$

$$= \frac{2^{\frac{1}{2}} \times \left(2^{\frac{1}{2}} x - \frac{x^2 - a^2}{2(2x^2)^{\frac{1}{2}}} + A(x^2 - a)^2 + \&c.\right) - 2a^{\frac{2}{3}} x^{\frac{1}{3}}}{x - a}$$

$$= \frac{2x^{\frac{1}{3}}(x^{\frac{2}{3}} - a^2) - \frac{x^2 - a^2}{2x} + A(x^2 - a^2)^2 + \&c.}{x - a}$$

$$= \frac{2x^{\frac{1}{3}}(x^{\frac{1}{3}} + a^{\frac{1}{3}})}{x^{\frac{2}{3}} + a^{\frac{1}{3}} x^{\frac{1}{3}} + a^{\frac{2}{3}}} - \frac{x + a}{2x} + A(x^2 - a^2)(x + a),$$

&c. $= (x = a)\ \frac{4}{3} - 1$ or $\frac{1}{3}$.

The ſimple rule for finding the value of theſe fractions is to take the differentials of the numerator and denominator:

Thus, in $F = \frac{x^2 - a^2}{x - a}$, $d(x^2 - a^2) = 2x\, d\, x$, $d(x - a)$

$d(x-a) = dx \therefore F = \frac{2x\,dx}{dx} = 2x = 2a$,

again, in $F = \frac{\sqrt{(2a^3x - x^4)} - a^3\sqrt{a^2x}}{a - \sqrt[4]{ax^3}} \left(\frac{N}{D}\right) d(N)$

$= \left\{ (a^3 - 2x^3)\ (2a^3x - x^4)^{-\frac{1}{2}} - \frac{1}{3}a^{\frac{1}{3}}x^{-\frac{2}{3}} \right\}$

$dx\,d(D) = -\frac{3}{4}a^{\frac{1}{4}}x^{-\frac{1}{4}} . dx$

when $x = a$, $d(N) = \left(-a^3 . (a^1)^{\frac{1}{3}} - \frac{a}{3}\right) dx = -\frac{4a}{3}$

and $d(D) = -\frac{3}{4} . dx \therefore F = \frac{d(N)}{d(D)} = \frac{9a}{1b}$.

This rule is ſufficient for the generality of caſes; and the proceſs continued will give the value of F; this continuation of the proceſs is neceſſary when after the firſt differentiation, and the ſubſtitution of $x = a$, the numerator and denominator each $= 0$: an inſtance of this caſe is $\frac{a^3\sqrt{(4a^3 + 4x)} - ax - a^2}{\sqrt{(2a^2 + 2x^2)} - x - a}$.

If after the ſecond differentiation, N and D each $= 0$, then continue the differentiation as long as N and D ſhall $= 0$.

Generally to find the value of $\frac{fx}{Fx}$, when fx, and Fx, $= 0$ on making $x = a$; for x ſubſtitute $a + (x - a)$,

then $fx = f(a + (x - a)) = fa + Dfa . (x - a) + \underset{c}{D^2}fa . (x - a)^2 +$ &c.

and $Fx = F(a + (x - a)) = Fa + DFa(x - a) + \underset{c}{D^2}Fa\,(x - a)^2 +$ &c.

but when $x = a$, fx, Fx, or fa, $Fa = 0$,

$$\therefore \frac{fx}{Fx} = \frac{Dfa + \underset{c}{D^2}fa . (x - a) + \text{&c.}}{DFa + \underset{c}{D^2}Fa\,(x - a) + \text{&c.}}$$

$=$ (putting $x = a$), $\frac{Dfa}{DFa}$, except Dfa, DFa likewiſe $= 0$, and then $\frac{fx}{Fx} = \frac{\underset{c}{D^2}fa + \underset{c}{D^3}fa . (x - a) + \text{&c.}}{\underset{c}{D^2}Fa + \underset{c}{D^3}Fa\,(x - a) + \text{&c.}}$

$=$ (putting $x = a$) $\frac{\underset{c}{D^2}fa}{\underset{c}{D^2}Fa}$, and if $\underset{c}{D^2}fa$, $\underset{c}{D^2}Fa$ likewiſe $= 0$, then $\frac{fx}{Fx} = \frac{D^3fa}{DFa}$, and generally, if the terms of the expanded ſeries up to the n^{th} terms, to wit, $\underset{c}{D^n}fa$, $\underset{c}{D^n}Fa$, $= 0$, then $\frac{fx}{Fx}(x = a) = \frac{D^nfa}{D^nFa}$.

This rule may be demonſtrated thus:

Let $y = \frac{fx}{Fx} \therefore y . Fx = fx \therefore \frac{dy}{dx} . Fx + \frac{dFx}{dx} = \frac{d . fx}{dx}$

but when $x = a$, by hypotheſis $Fx = 0$,

$$\therefore y = \frac{dFx}{dx} = \frac{dfx}{dx}, \text{ or } y = \frac{D . fx}{D . Fx}$$

which is the firſt part of the rule.

If when $Fx = 0$, DFx, $DFx = 0$ alſo; then by taking the differential of equation (1)

$\frac{d^2y}{dx^2} . Fx + \frac{2\,dy}{dx} . D . Fx + y\,D^2 . Fx = D^2 . fx$;

but when $x = a$, Fx, DFx, $= 0$ or $y = \frac{D^2fx}{D^2Fx}$, which is the proof of the ſecond part of the rule 1, or of the proceſs continued.

The values then of fractions, ſuch as $\frac{fx}{Fx}$, whoſe numerators and denominators vaniſh, on aſſigning particular values to x, may be computed by the preceding proceſs: which proceſs is arbitrary, and not neceſſarily to be followed, from any thing contained in the ſignificancy of the expreſſion $\left(\frac{fx}{Fx}\right)$. Propoſe the queſtion ſeparately, what does $\frac{x^m - a^m}{x^n - a^n}$ become $x = a$? and the obvious anſwer to any mind undebauched with mathematical ſophiſtry, is $\frac{a^m - a^m}{a^n - a^n}$ or $\frac{0}{0}$. A different reſult can be obtained by a different proceſs: but why ought that proceſs to be followed? No ſatisfactory anſwer can be given to this queſtion, when it is abſtractedly propoſed to find the value of $\frac{fx}{Fx}$, and we can only remove our doubts by viewing the circumſtances under which, in the application of analyſis, it is neceſſary to compute $\frac{fx}{Fx}$.

Now the fact is, that in inveſtigating the properties of extenſion, or of motion, the nature of the caſe directs us to follow, in computing the value of a vaniſhing fraction, a proceſs exactly ſimilar to that by which $\frac{fx}{Fx}$ has been computed; thus, if y be the ordinate of a curve, and $= \frac{x^2}{b}$, and y' be another ordinate, at an interval $(x' - x)$, and $= \frac{x'^2}{b}$, then $\frac{\text{ordinate}}{L}$ (L being a part of the axis intercepted between the points where the ordinate and a ſecant of the curve cut the axis) $= \frac{1}{b}\left(\frac{x'^2 - x^2}{x' - x}\right) = \frac{1}{b}(x' + x)$. Here x' is greater than x, and the line L approaches more nearly to the value of the ſubtangent, the nearer the points of interſection are, or the leſs the difference is between x' and x; and the tangent being, what the ſecant becomes, when the two points of interſection unite, the value of $\frac{\text{ordinate}}{\text{ſubtangent}}$ is expreſſed by the limit of $\frac{1}{b}\left(\frac{x'^2 - x^2}{x' - x}\right)$, or by what $\frac{1}{b}(x' + x)$ becomes, when $x' = x$, or by $\frac{2x}{b}$.

Hence, too, it appears, why in finding the value of $\frac{fx}{Fx}$, $a + (x - a)$, is put for x and not $(x - a)$: for ſince, in finding the ſubtangent or velocity, an expreſſion is required near to the truth, and which approaches to it the more nearly, the leſs is the interval between x and a (or x' and x), it is neceſſary to expand $\frac{fx}{Fx}$ by a ſeries that converges, and it is plain that $f((x - a) + a)$ is the ſymbol of a diverging, and $f(a + (x - a))$ of a converging ſeries.

Theſe vaniſhing fractions have cauſed many diſcuſſions amongſt mathematicians; they have cauſed many falſe

reaſonings. It was not perceived that, to aſſign the value of $\frac{x^m - a^m}{x^n - a^n}$ $(x = a)$, there was an abſolute neceſſity of ſome definition, convention, or extenſion. The notion of an inherent ſignification, and of an eſſential value, belonging to ſuch an expreſſion, as $\frac{x^m - a^m}{x^n - a^n}$, bewildered men who valued themſelves on the clearneſs of their apprehenſion, and the juſtneſs of their inferences.

The method of limits, or of prime and ultimate ratios, Landen's method, the method of finding the value of $\frac{f x}{\mathrm{F} x}$ $(f x, \mathrm{F} x = 0)$ are related methods: they all demand the ſame arbitrary aſſumption, which has never been expreſsly made; they are all equally ſubject to an objection, which has never been ſatisfactorily removed.

Such is the theory of theſe quantities as given by Mr. Woodhouſe, and which is ſo clear and ſatisfactory as to ſuperſede the neceſſity of any further inveſtigation.

It has been ſhewn that if φx denote a ſimple analytical function of x, $\varphi (x + \Delta x)$ expanded may be expreſſed by this formula, $\varphi x + \mathrm{D} \varphi x \cdot \Delta x + \overset{\mathrm{D}^2}{\mathrm{c}} \varphi x (\Delta x)^2 +$ &c.; D being the note of an operation by which the co-efficient of the ſecond term of the expanded expreſſion is obtained; thus if φx reſpectively repreſents x^m, a^x, e^x, $l \cdot x$; $\mathrm{D} \varphi x$ repreſents $m x^{m-1}$, $\mathrm{A} a^x$, e^x, $\frac{1}{x}$; now in the expanded expreſſion of $\varphi (x + \Delta x)$, for Δx put the ſymbol $\mathrm{d} x$, then $\varphi (x + \mathrm{d} x) = \varphi x + \mathrm{D} \varphi x \cdot \mathrm{d} x + \overset{\mathrm{D}^2}{\mathrm{c}} \varphi x \cdot (\mathrm{d} x)^2 +$ &c. and let d denote that operation by which the ſecond term of $\varphi (x + \mathrm{d} x)$ is found, in which caſe it muſt alſo denote the firſt term of the entire difference of $\varphi (x + \mathrm{d} x)$ and φx. Hence $\mathrm{d} \cdot \varphi x = \mathrm{D} \varphi x \cdot \mathrm{d} x$, conſequently $\mathrm{D} \varphi x = \frac{\mathrm{d} \varphi x}{\mathrm{d} x}$; again $\mathrm{d} (\mathrm{d} \varphi x)$ = firſt term of $\left(\mathrm{D} \varphi (x + \mathrm{d} x) - \mathrm{D} \varphi x\right)$, $\mathrm{d} x$ expanded $= \mathrm{D}^2 \varphi x \cdot (\mathrm{d} x)^2$, conſequently $\mathrm{D}^2 \varphi x = \frac{\mathrm{d} \cdot (\mathrm{d} \varphi x)}{(\mathrm{d} x)^2} = \frac{\mathrm{d}^2 \varphi x}{\mathrm{d} x^2}$ (employing $\mathrm{d} x^2$, $\mathrm{d} x^3$..... $\mathrm{d} x^n$ to repreſent $(\mathrm{d} x)^2$ $((\mathrm{d} x)^3$ ..... $(\mathrm{d} x)^n)$; again $\mathrm{d} (\mathrm{d}^2 \varphi x)$ or $\mathrm{d}^2 \varphi x = \mathrm{D} (\mathrm{d}^2 \varphi x) \mathrm{d} x = \mathrm{D} (\mathrm{D}^2 \varphi x \cdot \mathrm{d} x^2) \cdot \mathrm{d} x = \mathrm{D}^3 \varphi x \cdot \mathrm{d} x^3$; conſequently $\mathrm{D}^3 \varphi x = \frac{\mathrm{d}^3 \varphi x}{\mathrm{d} x^3}$; and generally $\mathrm{D}^n \varphi x = \frac{\mathrm{d}^n \varphi x}{\mathrm{d} x^n}$. The expanded form for $\varphi (x + \Delta x)$ may then be thus repreſented;

$$\varphi x + \frac{\mathrm{d} \varphi x}{\mathrm{d} x} \cdot \Delta x + \frac{\overset{\mathrm{d}^2}{\mathrm{c}} \varphi x}{\mathrm{d} x^2} \cdot (\Delta x)^2 + \&\mathrm{c.}$$

and ſimilarly

$$\varphi (x + \mathrm{d} x) = \varphi x + \frac{\mathrm{d} \varphi x}{\mathrm{d} x} \cdot \mathrm{d} x + \frac{\overset{\mathrm{d}^2}{\mathrm{c}} \varphi x}{\mathrm{d} x^2} \cdot \mathrm{d} x^2 + \&\mathrm{c.}$$

The difference between $\varphi (x + \mathrm{d} x)$ and φx is called the *entire difference*, and its note or ſymbol is Δ; thus $\Delta \varphi x$ or $\varphi (x + \mathrm{d} x) - \varphi x = \frac{\mathrm{d} \varphi x}{\mathrm{d} x} \cdot \mathrm{d} x + \frac{\overset{\mathrm{d}^2}{\mathrm{c}} \varphi x}{\mathrm{d} x^2} +$ &c. A part of this entire difference, *viz.* the ſecond term, is called the *differential*, and its note or ſymbol is d; thus $\mathrm{d} (\varphi x) = \frac{\mathrm{d} \varphi x}{\mathrm{d} x} \mathrm{d} x$, or $\mathrm{D} \varphi x \cdot \mathrm{d} x$; the ſecond, third, &c. nth terms of the ſeries for $\Delta \varphi x$ (abſtracting the numerical part of the co-efficients) are called the 2d, 3d, &c. nth differentials; thus,

$$\Delta \varphi x = \frac{\mathrm{d} \varphi x}{\mathrm{d} x} \cdot \mathrm{d} x + \frac{\mathrm{d}^2 \varphi x}{1 \cdot 2 \cdot \mathrm{d} x^2} \cdot \mathrm{d} x^2 + \frac{\mathrm{d}^3 \varphi x}{1 \cdot 2 \cdot 3 \cdot \mathrm{d} x^3} \cdot \mathrm{d} x^3 + \&\mathrm{c.}$$

and $\frac{\overset{\mathrm{d}^2}{\mathrm{c}} \varphi x}{\mathrm{d} x^2} \cdot \mathrm{d} x^2$, $\frac{\overset{\mathrm{d}^3}{\mathrm{c}} \varphi x}{\mathrm{d} x^3} \cdot \mathrm{d} x^3$ &c. $\frac{\overset{\mathrm{d}^n}{\mathrm{c}} \varphi x}{\mathrm{d} x^n} \cdot \mathrm{d} x^n$ are the ſecond, third, nth, &c. differentials.

Since Δ is the note of the entire difference, and d of the firſt term of that difference, when theſe notes are applied to a ſimple quantity, as x, they are equally ſignificant; thus $\Delta x = \mathrm{d} x$. $\frac{\mathrm{d} \varphi x}{\mathrm{d} x}, \frac{\mathrm{d}^2 \varphi x}{\mathrm{d} x^2}$, &c. are to be conſidered as types of calculation; thus $\frac{\mathrm{d} \varphi x}{\mathrm{d} x}$ denotes, that in φx, for x, $x + \mathrm{d} x$ is to be put, and the co-efficient of the ſecond term of $\varphi (x + \mathrm{d} x)$ expanded to be taken; $\frac{\mathrm{d} \varphi x}{\mathrm{d} x}, \frac{\mathrm{d}^2 \varphi x}{\mathrm{d} x^2}$, &c. are called the differential co-efficients.

A few inſtances will ſhew the ſignification of the ſymbols Δ, D, d;

$$\Delta x^m = m x^{m-1} \cdot \Delta x + \frac{m \cdot (m-1)}{1 \cdot 2} x^{m-2} \cdot (\Delta x)^2 + \&\mathrm{c.}$$

when $\Delta x^m = (x + \Delta x)^m - x^m$, or $= m x^{m-1} \cdot \mathrm{d} x + \frac{m \cdot (m-1)}{1 \cdot 2} x^{m-2} \cdot \mathrm{d} x^2 +$ &c.

when $\Delta x^m = (x + \mathrm{d} x)^m - x^m$;

$\mathrm{D} x^m = m x^{m-1}$, ſince $\mathrm{D} x^m$ denotes the ſecond term of $(x + 1)^m$ expanded, to be taken

$\mathrm{d} (x^m) = m x^{m-1} \mathrm{d} x$; x^m is included within brackets to prevent ambiguity, ſince $\mathrm{d} x^m$ has already been uſed to denote $(\mathrm{d} x)^m$.

Again, if $x + \Delta x$ be put for x, $\Delta a^x = \mathrm{A} a^x \cdot \Delta x + \frac{\mathrm{A}^2 a^x}{1 \cdot 2} \cdot (\Delta x)^2 +$ &c.;

if $x + \mathrm{d} x$ be put for x, $\Delta a^x = \mathrm{A} a^x \cdot \mathrm{d} x + \frac{\mathrm{A}^2 a^x}{1 \cdot 2} \cdot (\mathrm{d} x)^2 +$ &c.

$\mathrm{D} a^x =$ (ſecond term of a^{x+1} expanded) $= \mathrm{A} a^x$, $\mathrm{d} (a) = \mathrm{A} a^x \cdot \mathrm{d} x$, and $\mathrm{d} (e) = e^x \cdot \mathrm{d} x$.

Again, $l \cdot x$ being dependant on the equation $x = e^{l \cdot x}$, $\Delta l \cdot x =$ (the difference between two ſucceſſive values of x being Δx)

$$\frac{\Delta x}{x} - \tfrac{1}{2} \cdot \left(\frac{\Delta x}{x}\right)^2 + \tfrac{1}{3} \cdot \left(\frac{\Delta x}{x}\right)^3 - \&\mathrm{c.}$$

$$\mathrm{D} l \cdot x = \frac{1}{x},$$

$$\mathrm{d} (l \cdot x) = \frac{\mathrm{d} x}{x}.$$

Generally, if y be any function (φx) of x, and $y + \Delta y$ be what y becomes, when $x + \Delta x$ is put for x; then $\Delta y = \varphi (x + \Delta x) - \varphi x = \mathrm{D} \varphi x \cdot \Delta x + \overset{\mathrm{D}^2}{\mathrm{c}} \varphi x \cdot (\Delta x)^2 +$ &c. or $= \frac{\mathrm{d} y}{\mathrm{d} x} \Delta x + \frac{\overset{\mathrm{d}^2}{\mathrm{c}} y}{\mathrm{d} x^2} (\Delta x)^2 +$ &c.; in which formula $\frac{\mathrm{d} y}{\mathrm{d} x}, \frac{\overset{\mathrm{d}^2}{\mathrm{c}} y}{\mathrm{d} x^2}$, &c. are to be conſidered as types of calculation, $\frac{\mathrm{d} y}{\mathrm{d} x}$ denoting that in y a function of x, $x + \mathrm{d} x$ is to

to be put for x, and the co-efficient of the ſecond term of the expanded expreſſion is to be taken.

To find the entire difference, and the differential of y, a function of p, q, r, s, &c. when p, q, r, s, &c. are ſimple functions of x.

Then when x becomes $x + \Delta x$, p becomes $p + \Delta p$, q becomes $q + \Delta q$, &c. and y becomes $y + \Delta y$; and

$$y + \Delta y = y^{2} + \mathrm{D}y \cdot \Delta x + \overset{\mathrm{D}^{2}}{c} y\,(\Delta x)^{2} + \overset{\mathrm{D}^{3}}{c} y\,(\Delta x)^{3}$$

$$p + \Delta p = p^{2} + \mathrm{D}p \cdot \Delta x + \overset{\mathrm{D}^{2}}{c} p\,(\Delta x)^{2} + \overset{\mathrm{D}^{3}}{c} p\,(\Delta x)^{3}$$

$$q + \Delta q = q^{2} + \mathrm{D}q \cdot \Delta x + \overset{\mathrm{D}^{2}}{c} q\,(\Delta x)^{2} + \overset{\mathrm{D}^{3}}{c} q\,(\Delta x)^{3}$$

$$r + \Delta r = r^{2} + \mathrm{D}r \cdot \Delta x + \overset{\mathrm{D}^{2}}{c} r\,(\Delta x)^{2} + \overset{\mathrm{D}^{3}}{c} r\,(\Delta x)^{3}$$

Therefore in the expreſſion for the value of y ſubſtitute the new values of p, q, r, &c. and the co-efficient of Δx ſhall be equal $\mathrm{D}y$, or the differential co-efficient of y.

Example 1ſt.—Let $y = ap + q + r$ &c.

Then ſince $y + \mathrm{D}y \cdot \Delta x + \overset{\mathrm{D}^{2}}{c} y\,(\Delta x)^{2}$

$$= p + \mathrm{D}p \cdot \Delta x + \overset{\mathrm{D}^{2}}{c} p\,(\Delta x)^{2} \text{ &c.}$$
$$+ q + \mathrm{D}q \cdot \Delta x + \overset{\mathrm{D}^{2}}{c} q\,(\Delta x)^{2} \text{ &c.}$$
$$+ r + \mathrm{D}r \cdot \Delta x + \overset{\mathrm{D}}{c} r\,(\Delta x)^{2} \text{ &c.}$$
$$\mathrm{D}y = \mathrm{D}p + \mathrm{D}q + \mathrm{D}r \text{ &c.}$$

Therefore

$$\mathrm{d}y = \mathrm{D}y \cdot \mathrm{d}x = \mathrm{D}p \cdot \mathrm{d}x + \mathrm{D}q \cdot \mathrm{d}x + \mathrm{D} \cdot r \cdot \mathrm{d}x \text{ &c.}$$
$$= \frac{\mathrm{d}y}{\mathrm{d}x} \cdot \mathrm{d}x = \frac{\mathrm{d}p}{\mathrm{d}x} \cdot \mathrm{d}x + \frac{\mathrm{d}y}{\mathrm{d}x}\,\mathrm{d}x + \frac{\mathrm{d}r}{\mathrm{d}x} \text{ &c.}$$

The entire difference $\Delta y =$ evidently

$$\Delta (p + q + r + \text{&c.}) = (\mathrm{D}p + \mathrm{D}q + \mathrm{D}r)\,\Delta x + (\overset{\mathrm{D}^{2}}{c} p + \overset{\mathrm{D}^{2}}{c} q + \overset{\mathrm{D}}{c} r \text{ &c})\,\Delta x^{2} + \text{&c.}$$

Let y be a ſimple function of p, then p becomes $p + \Delta p$; y becomes $y + \frac{\mathrm{d}y}{\mathrm{d}p} \cdot \Delta p + \frac{\mathrm{d}^{2}y}{\mathrm{d}p^{2}} \cdot \frac{\Delta p^{2}}{1.2} + \frac{\mathrm{d}^{3}y}{\mathrm{d}p^{3}} \cdot \frac{\Delta p^{3}}{1.2.3}$.

If p be at the ſame time ſuppoſed a function of x, then x becoming $x + \Delta x$, y becomes likewiſe $y + \Delta y = y + \frac{\mathrm{d}y}{\mathrm{d}x} \cdot \Delta x + \frac{\mathrm{d}^{2}y}{\mathrm{d}x^{2}} \cdot \frac{\Delta x^{2}}{1.2} + \frac{\mathrm{d}^{3}y}{\mathrm{d}x^{3}} \cdot \frac{\Delta x^{3}}{1.2.3}$.

Now p being conſidered as a function of x, x becoming $x + \Delta x$, p becomes

$$p + \frac{\mathrm{d}p}{\mathrm{d}x} \cdot \Delta x + \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} \cdot \frac{\Delta x^{2}}{1.2} + \frac{\mathrm{d}^{3}p}{\mathrm{d}x^{3}} \cdot \frac{\Delta x^{3}}{1.2.3} \text{ &c.}$$

$$\therefore \Delta p = \frac{\mathrm{d}p}{\mathrm{d}x} \cdot \Delta x + \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} \cdot \frac{\Delta x^{2}}{1.2} + \frac{\mathrm{d}^{3}p}{\mathrm{d}x^{3}} \cdot \frac{\Delta x^{3}}{1.2.3} \text{ &c.}$$

Now ſubſtitute this value of Δp in the equation for the value of $y + \Delta y$,

$$y + \Delta y = y + \frac{\mathrm{d}y}{\mathrm{d}p} \cdot \frac{\mathrm{d}p}{\mathrm{d}x} \cdot \Delta x + \frac{\mathrm{d}y}{\mathrm{d}p} \cdot \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} \cdot \frac{\Delta x^{2}}{1.2} + \frac{\mathrm{d}y}{\mathrm{d}p} \cdot \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} \cdot \frac{\Delta x^{3}}{1.2.3} + \text{&c.} + \frac{\mathrm{d}^{2}y}{\mathrm{d}p^{2}} \cdot \frac{1}{2}\left(\frac{\mathrm{d}p}{\mathrm{d}x} \cdot \Delta x + \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} \cdot \frac{\Delta x^{2}}{1.2} + \text{&c.}\right)^{2} + \text{&c.}$$

Then by comparing the co-efficients of Δx in the two values of y,

$$\frac{\mathrm{d}y}{\mathrm{d}x} = \frac{\mathrm{d}y}{\mathrm{d}p} \cdot \frac{\mathrm{d}p}{\mathrm{d}x} \quad \therefore \frac{\mathrm{d}y}{\mathrm{d}p} = \frac{\frac{\mathrm{d}y}{\mathrm{d}x}}{\frac{\mathrm{d}p}{\mathrm{d}x}}$$

$$\frac{\mathrm{d}^{2}y}{\mathrm{d}x^{2}} = \frac{\mathrm{d}y}{\mathrm{d}p} \cdot \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} + \frac{\mathrm{d}^{2}y}{\mathrm{d}p^{2}}\left(\frac{\mathrm{d}p}{\mathrm{d}x}\right)^{2}$$

$$\text{And } \frac{\mathrm{d}^{2}y}{\mathrm{d}p^{2}} = \frac{\frac{\mathrm{d}y^{2}}{\mathrm{d}x^{2}} - \frac{\mathrm{d}y}{\mathrm{d}p} \cdot \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}}}{\left(\frac{\mathrm{d}p}{\mathrm{d}x}\right)^{2}}$$

$$= \frac{\frac{\mathrm{d}^{2}y}{\mathrm{d}x^{2}} - \frac{\frac{\mathrm{d}y}{\mathrm{d}x}}{\frac{\mathrm{d}p}{\mathrm{d}x}} \cdot \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}}}{\left(\frac{\mathrm{d}p}{\mathrm{d}x}\right)^{2}}$$

$$= \frac{\frac{\mathrm{d}^{2}y}{\mathrm{d}x^{2}}}{\left(\frac{\mathrm{d}p}{\mathrm{d}x}\right)^{3}} - \frac{\frac{\mathrm{d}y}{\mathrm{d}x} \cdot \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}}}{\left(\frac{\mathrm{d}p}{\mathrm{d}x}\right)^{3}}$$

Example 2d.—Let $y = (ax - x^{2})^{\frac{1}{2}}$ required the values of $\frac{\mathrm{d}y}{\mathrm{d}x}, \frac{\mathrm{d}^{2}y}{\mathrm{d}x^{2}}, \frac{\mathrm{d}^{3}y}{\mathrm{d}x^{3}}$, &c. Put $ax - x^{2} = p$:

$$\frac{\mathrm{d}p}{\mathrm{d}x} = a - 2x$$

$$\frac{\mathrm{d}y}{\mathrm{d}p} = \tfrac{1}{2}p^{-\frac{1}{2}} = \frac{1}{2\sqrt{ax - x^{2}}}$$

$$\therefore \frac{\mathrm{d}y}{\mathrm{d}x} = \frac{\mathrm{d}y}{\mathrm{d}p} \cdot \frac{\mathrm{d}p}{\mathrm{d}x} = \frac{a - 2x}{2\sqrt{ax - x^{2}}}.$$

Again $\frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} = 2 \therefore \frac{\mathrm{d}y}{\mathrm{d}p} \cdot \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} = \frac{1}{\sqrt{ax - x^{2}}} =$ 1ſt term

$$\left(\frac{\mathrm{d}p}{\mathrm{d}x}\right)^{2} = \overline{a - 2x}^{2}$$

$$\frac{\mathrm{d}^{2}y}{\mathrm{d}p^{2}} = -\tfrac{1}{4}p^{-\frac{3}{2}} = -\frac{1}{4\sqrt{(ax - x^{2})^{3}}}$$

$$\therefore \left(\frac{\mathrm{d}p}{\mathrm{d}x}\right)^{2} \cdot \frac{\mathrm{d}^{2}y}{\mathrm{d}p^{2}} = -\frac{(a - 2x)^{2}}{4\sqrt{(ax - x^{2})^{3}}}$$

$$\therefore \frac{\mathrm{d}^{2}y}{\mathrm{d}x^{2}} = \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} \cdot \frac{\mathrm{d}y}{\mathrm{d}p} + \left(\frac{\mathrm{d}p}{\mathrm{d}x}\right)^{2} \cdot \frac{\mathrm{d}^{2}y}{\mathrm{d}p^{2}} = \frac{1}{\sqrt{ax - x^{2}}} - \frac{(a - 2x)^{2}}{4\sqrt{(ax - x)^{3}}}$$

Example 3d: $y = (x^{2} - a^{2})^{\frac{1}{2}}$ $p = (x^{2} - a^{2})$

$$\frac{\mathrm{d}p}{\mathrm{d}x} = 2x$$

$$\frac{\mathrm{d}y}{\mathrm{d}p} = \tfrac{1}{2}p^{-\frac{1}{2}} = \frac{1}{2\sqrt{x^{2} - a^{2}}}$$

$$\frac{\mathrm{d}y}{\mathrm{d}x} = \frac{x}{\sqrt{x^{2} - a^{2}}}$$

$$\frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} = 2; \quad \frac{\mathrm{d}y}{\mathrm{d}p} \cdot \frac{\mathrm{d}^{2}p}{\mathrm{d}x^{2}} = \frac{1}{\sqrt{x^{2} - a^{2}}} = \text{1ſt term}$$

$$\left(\frac{\mathrm{d}p}{\mathrm{d}x}\right)^{2} = 4x^{2}$$

$$\frac{\mathrm{d}^{2}y}{\mathrm{d}p^{2}} = -\tfrac{1}{4}p^{-\frac{3}{2}} = -\frac{1}{4(x^{2} - a^{2})^{\frac{1}{2}}}$$

$$\left(\frac{\mathrm{d}p}{\mathrm{d}x}\right)^{2}$$

$\left(\frac{d p}{d x}\right)^2 \cdot \frac{d^2 y}{d p^2} = \frac{-x^2}{(x^2 - a^2)^{\frac{1}{2}}}$ = 2d term

$\frac{d^2 y}{d x^2} = \frac{1}{\sqrt{x^2 - a^2}} - \frac{x^2}{(x^2 - a^2)^{\frac{1}{2}}}$

Example 4th.—Let $y = b + (r^2 - (a - x)^2)^{\frac{1}{2}}$

Suppoſe $(a - x)^2 = p$; then $y = (r^2 - p)^{\frac{1}{2}}$ required the value of $\frac{d y}{d x}$ and $\frac{d^2 y}{d x^2}$

$\frac{d p}{d x} = 2x - 2a$

$\frac{d y}{d p} = \frac{1}{2}(r^2 - p)^{-\frac{1}{2}} \therefore \frac{d p}{d x} \cdot \frac{d y}{d p} = \frac{d y}{d x} = \frac{x - a}{(r^2 - (a-x)^2)^{\frac{1}{2}}}$

$\frac{d^2 p}{d x^2} = 2 \therefore \frac{d y}{d p} \cdot \frac{d^2 p}{d x^2} = \frac{1}{\sqrt{r^2 - (a - x)^2}}$

$\left(\frac{d p}{d x}\right)^2 = 4(a - x)^2$

$\frac{d^2 y}{d p^2} = -\frac{1}{4}(r^2 - p)^{-\frac{3}{2}} = \frac{1}{4(r^2 - (a-x)^2)^{\frac{3}{2}}}$

$\left(\frac{d p}{d x}\right)^2 \cdot \frac{d^2 y}{d p^2} = -\frac{(a-x)^2}{(r^2 - (a-x)^2)^{\frac{1}{2}}}$

$\therefore \frac{d^2 y}{d x^2} = \frac{1}{\sqrt{r^2 - (a-x)^2}} + \frac{-(a-x)^2}{(r^2 - (a-x)^2)^{\frac{3}{2}}}$

$= \frac{r^2 - (a-x)^2}{(r^2 - (a-x)^2)^{\frac{3}{2}}} + \frac{(a-x)^2}{(r^2 - (a-x)^2)^{\frac{3}{2}}} = \frac{r^2}{(r^2 - (a-x)^2)^{\frac{1}{2}}}$

Example 5th. Let $y = (x - a)^2 \cdot \sqrt{x - b}$

$p = (x - a)^2$
$q = (x - b)^{\frac{1}{2}}$

$\frac{d y}{d x} = p \cdot \frac{d q}{d x} + q \cdot \frac{d p}{d x}$

$= (x-a)^2 \cdot \frac{1}{2}(x-b)^{-\frac{1}{2}} + (x-b)^{\frac{1}{2}} \cdot 2(x-a)^1$

$= \frac{(x-a)^2}{2\sqrt{x-b}} + 2(x-a) \cdot \sqrt{x-b}$

$\frac{d^2 y}{d x^2} = p \cdot \frac{d q}{d x^2} + q \cdot \frac{d^2 p}{d x^2} + 2\left(\frac{d p}{d x} \cdot \frac{d q}{d x}\right)$

$= (x-a)^2 \cdot \frac{1}{4}(x-b)^{-\frac{3}{2}} + (x-b)^{\frac{1}{2}} \cdot 2(x-a)^{1-1}$
$+ 2(x-a) \cdot \frac{1}{2}(x-b)^{-\frac{1}{2}}$

$= 2\sqrt{x-b} + \frac{2(x-a)}{\sqrt{x-b}} - \frac{(x-a)^2}{4(x-b)^{\frac{3}{2}}}$

Let it now be required to find the differential of $\varphi(p, q)$, p and q being functions of x.

Let p become $p + \Delta p$, and q, $q + \Delta q$, then $\varphi(p, q)$ becomes $q(p + \Delta p, q + \Delta q)$, in which latter form $p + \Delta p$, $q + \Delta q$, are to be combined in the ſame manner as p, q are in $\varphi(p, q)$, hence expanding $\varphi(p + \Delta p, q + \Delta q)$, according to the powers of Δp,

$\varphi(p + \Delta p, q + \Delta q) = \varphi(p, q + \Delta q) + \frac{d(\varphi p, q + \Delta q)}{d p} \cdot \Delta p$
$+ \frac{d^2 \varphi(p, q + \Delta q)}{1 \cdot 2 \cdot d p^2} \cdot (\Delta p)^2 + \&c.$

= (expanding $\varphi(p, q + \Delta q)$, &c.)

$\varphi(p, q) + \frac{d \varphi(p, q)}{d q} \cdot \Delta p + \frac{d^2 \varphi(p, q)}{1 \cdot 2 \cdot d q^2} (\Delta q)^2 + \&c.$
$+ \frac{d \varphi(p, q)}{d p} \cdot \Delta p + \frac{d^2 \varphi(p, q)}{d p \cdot d q} \cdot \Delta p \cdot \Delta q + \&c.$

in which form the ſymbols $\frac{d \varphi(p, q)}{d q}$, $\frac{d \varphi(p, q)}{d p}$, reſpectively denote the differential co-efficients of $\varphi(p, q)$, on the hypotheſis, that q is alone variable in $\varphi(p, q)$, and that p is alone variable in $\varphi(p, q)$; hence putting $d q$, $d p$, for Δq, Δp, the differential of $\varphi(p, q)$, or the term affected with $d x$ (ſince $d p = \frac{d p}{d x} \cdot d x$, $d q = \frac{d q}{d x} \cdot d x$) $= \frac{d \varphi(p, q)}{d q} \cdot d q + \frac{d \varphi(p, q)}{d p} \cdot d p$.

If P be put for $\varphi(p, q)$, then the ſymbols $\frac{d \varphi(p, q)}{d q}$, $\frac{d \varphi(p, q)}{d p}$ are expreſſed by $\frac{d P}{d q}$, $\frac{d P}{d p}$, conſequently the differential of P or $d P = \frac{d P}{d q} \cdot d q + \frac{d P}{d p} \cdot d p$.

In like manner, if P denote a function of p, q, r, s, &c. or $= \varphi(p, q, r, s, \&c.)$ then its differential $= \frac{d P}{d p} \cdot d p + \frac{d P}{d q} \cdot d q + \frac{d P}{d r} \cdot d r + \frac{d P}{d s} \cdot d s + \&c.$

The expreſſions $\frac{d P}{d p} \cdot d p$, $\frac{d P}{d q} \cdot d q$, &c. are called partial differentials of the function P, and $\frac{d P}{d p}$, $\frac{d P}{d q}$, &c. partial differential co-efficients.

Ex. Let $\varphi(p, q)$ or P be repreſented by $(1 + p^2)^m \cdot e^q$, then $\frac{d P}{d q} = 2mp \cdot (1 + p^2)^{m-1} e^q$ $\frac{d P}{d q} = (1 + p^2)^m \cdot e^q$,

$\therefore d P = 2mp\, d q \cdot (1 + p^2)^{m-1} \cdot e^q + e^q d q \cdot (1 + p^2)^m$; again, let $P = p^2 (2pq + q^2)^{\frac{1}{2}}$,

then $\frac{d P}{d q} = (2pq + q^2)^{\frac{1}{2}} + \frac{qp}{(2pq + q^2)^{\frac{1}{2}}} = \frac{3pq + q^2}{(2pq + q^2)^{\frac{1}{2}}}$

$\frac{d P}{d q} = \frac{p^2 + pq}{(2pq + q^2)^{\frac{1}{2}}}$

$\therefore d P = \frac{3pq + q^2}{(2pq + q^2)^{\frac{1}{2}}} \cdot d p + \frac{p^2 + pq}{(2pq + q^2)^{\frac{1}{2}}} \cdot d q$.

Suppoſe now y to be determined by an equation between x and y, as in $y^2 - 2xy + x^2 - a^2 = 0$, $x^3 - axy + y^3 = 0$; in which caſes y is ſaid to be an implicit function of x, the explicit functions being thoſe which are under the form $y = ax + bx^2 + cx^3 + \&c.$ $y = \frac{1 + \alpha x}{1 + \beta x^2 + \gamma x^3}$ &c.; and let the equation on which the value of the implicit function of y depends, be generally repreſented by $\varphi(x, y) = 0$; then if y can thence be determined to be a function of x, when x becomes $x + \Delta x$, y becomes $y + D \cdot y \cdot \Delta x + \frac{D^2}{c} \cdot y \cdot (\Delta x)^2 + \&c.$

$\therefore$ Subſtituting in the equation $\varphi(x, y) = 0$, for x and y the above values, we have $\varphi\left(x + \Delta x, y + D \cdot y \cdot \Delta x + \frac{D^2}{c} y \cdot (\Delta x)^2 + \&c.\right) = 0$; or putting $\varphi(x, y) = X$, and expanding $X + \frac{d(X)}{d x} \cdot \Delta x + \frac{d^2(X)}{d x^2} \cdot (\Delta x)^2$ &c. $= 0$,

and as this equation ſubſiſts, whatever Δx is, each ſeparate co-efficient affected with a different power of Δx muſt be put $= 0$;

hence $\frac{d(X)}{dx} = 0$, or $\frac{dX}{dy} \cdot \frac{dy}{dx} + \frac{dX}{dx} = 0$;

again $\frac{d^2X}{dx^2} = 0$, or

$$\frac{dX}{dy} \cdot \frac{d^2y}{dx^2} + \frac{dX}{dy \cdot dx} \cdot \frac{dy}{dx} + \frac{d^2X}{dy^2}\left(\frac{dy}{dx}\right) + \frac{d^2X}{dx^2} = 0;$$

again $\frac{d^3X}{dx^3} = 0$, or &c. &c.

in which forms $\frac{dX}{dy}$ means the partial differential co-efficient of X, or $\varphi(x, y)$ relatively to y, $\frac{d^2X}{dx \cdot dy}$ the partial differential co-efficient of X, when the differential is taken twice, firſt relatively to x, and next relatively to y.

Hence it follows, that when there is an equation between two variable quantities x, y, the equation likewiſe ſubſiſts between their firſt differential equations, between their ſecond differential equations, &c. and ſo on.

Ex. $y^2 + 2xy + m^2x^2 - a^2 = 0$

$\therefore 2y\,dy + 2x\,dy + 2y\,dx + 2m^2x\,dx = 0$

$\therefore \frac{dy}{dx} = -\frac{y + m^2x}{y + x}$.

Again, let $y^3 + 3axy + x^3 = 0$

$\therefore 3y^2\,dy - 3ax\,dy - 3ay\,dx + 3x^2\,dx = 0$

$\therefore \frac{dy}{dx} = \frac{3ay - 3x^2}{3y^2 - 3ax} = \frac{ay - x^2}{y^2 - ax}$.

When $y = \frac{fx}{Fx}$, or when y repreſents ſuch a function of x as $\frac{fx}{Fx}$, $y\,Fx = fx$.

But it has been ſhewn that $d(y\,Fx) = d(fx)$; or expanding $Fx \cdot \frac{dy}{dx} \cdot dx + y\frac{dFx}{dx} \cdot dx = \frac{dfx}{dx} \cdot dx$; or ſince $Dy = \frac{dy}{dx}$, $DFx = \frac{dFx}{dx}$, &c.

$Fx \cdot D \cdot y + y \cdot DFx = Dfx$.

Suppoſe now $\frac{fx}{Fx}$ to be one of thoſe fractions whoſe numerators and denominators vaniſh on giving x a particular value (a); put $x = a$, then $Fx = 0$, and the preceding equation becomes

$$y \cdot \frac{dFx}{dx} = \frac{dfx}{dx} \qquad \text{and } y = \frac{\frac{dfx}{dx}}{\frac{dFx}{dx}}$$

$$\text{or} = \frac{Dfx}{DFx},$$

which is the ſame reſult as was found above, as indeed it muſt neceſſarily be, ſince each method is derived from the ſame ſource, and conducted by a like reaſoning.

If it ſo happens that Dfx, DFx, become nothing when $x = a$, then the ſecond differential of the equation $y\,Fx = fx$ muſt be taken, thus ſince it has been proved that $Fx \cdot D \cdot y + y \cdot DFx = Dfx$,

$$d(Fx \cdot D \cdot y) + d(y \cdot DFx) = d(Dfx),$$

or $dFx \cdot D \cdot y + Fx \cdot d(D \cdot y) + dy \cdot DFx + y\,d(DFx) = d(Dfx)$,

or $DFx \cdot D \cdot y + Fx \cdot D^2 \cdot y + D \cdot y \cdot DFx + y \cdot D^2Fx = D^2fx$, (putting for dFx, dy, their values $DFx \cdot dx$, $D \cdot y \cdot dx$, and dividing every term by dx),

or $2\,DFx \cdot D \cdot y + Fx \cdot D^2 \cdot y + y \cdot DFx = D^2fx$;

putting $x = a$, ſince by hypotheſes fx, Fx, Dfx, $DFx = 0$, the above equation is reduced to $y \cdot D^2Fx = D^2fx$, and conſequently $y = \frac{D^2fx}{DFx}$, the ſame reſult as already given, and the two reſults muſt neceſſarily agree, being derived from the ſame principle, and by the ſame proceſs.

If D^2fx, D^2Fx, putting $x = a$, likewiſe become 0, then the third differential of the equation $y\,Fx = fx$ muſt be taken, and then we ſhall obtain $y\frac{D^3fx}{D^3Fx}$, and ſo on.

The following inveſtigation of the differential of the ſines and coſines of angles is given by Lagrange, but the notation uſed by Mr. Woodhouſe is ſubſtituted inſtead of that given in the "Fonctions Analytiques."

$$\text{ſin.}(x + y) = \text{ſin. } x \cdot \text{coſ. } y + \text{coſ. } x \cdot \text{ſin. } y$$
$$\text{coſ.}(x + y) = \text{coſ. } x \cdot \text{coſ. } y - \text{ſin. } x \cdot \text{ſin. } y$$

For x ſubſtitute $x + \Delta x$, and expand the functions ſin. $(x + \Delta x)$ and coſ. $(x + \Delta x)$ according to the powers of Δx; the co-efficients of Δx in theſe expanſions will be the derived functions or differential co-efficients required. By the preceding formulæ

$$\text{ſin.}(x + \Delta x) = \text{ſin. } x \cdot \text{coſ. } \Delta x + \text{coſ. } x \cdot \text{ſin. } \Delta x$$
$$\text{coſ.}(x + \Delta x) = \text{coſ. } x \cdot \text{coſ. } \Delta x - \text{ſin. } x \cdot \text{ſin. } \Delta x$$

It remains now to expand into ſeries the quantities ſin. Δx, coſ. Δx.

Aſſuming with Lagrange that the ſeries for the ſin. Δx muſt be of this form $A(\Delta x)^m + B(\Delta x)^n +$ &c. m and n being whole numbers and increaſing, then making x and $y = \Delta x$

ſin. $2 \cdot \Delta x = 2$ ſin. $\Delta x \cdot$ coſ. $\Delta x = 2$ ſin. $\Delta x \sqrt{1 - \text{ſin.}^2 \Delta x}$; and ſince the ſine of $\Delta x = A(\Delta x)^m + B\Delta x^n +$ &c.

ſin. $2\Delta x = 2^m \cdot A(\Delta x)^m + 2^n \cdot B(\Delta x)^n +$ &c.

Alſo, ſin.$^2 \Delta x = A^2(\Delta x)^{2m} + 2A \cdot B \cdot (\Delta x)^{m+n}$ &c. and $\sqrt{1 - \text{ſin.}^2 \Delta x} = (1 - \text{ſin.}^2 \Delta x)^{\frac{1}{2}} = 1 - \frac{1}{2}A^2\Delta x^{2m} - A \cdot B \cdot (\Delta x)^{m+n} -$ &c. therefore $2\,\text{ſin.}\,\Delta x \sqrt{1 - \text{ſin.}^2 \Delta x} = 2A(\Delta x)^m + 2B(\Delta x)^n +$ &c. $- A^3(\Delta x)^{3m} -$ &c. which ſeries being identical with the following:

$$2^m A(\Delta x)^m + 2^n B(\Delta x)^n + \text{&c.}$$

which expreſſes the value of ſin. $2\Delta x$; the compariſon of the firſt terms which contain the ſame power $(\Delta x)^m$ will give

$$2A = 2^m A; \text{ hence } m = 1.$$

Hence it appears that the firſt term of the ſeries of ſin. Δx is $A \cdot \Delta x$, conſequently, the two firſt terms of the ſeries for coſ. Δx will be $1 - \frac{A^2\Delta x^2}{2}$, making theſe ſubſtitutions in the expreſſions ſin. $(x + \Delta x)$ and coſ. $(x + \Delta x)$, and conſidering only the firſt power of Δx,

$$\text{ſin.}(x + \Delta x) = \text{ſin. } x + A \cdot \Delta x \cdot \text{coſ. } x + \text{&c.}$$
$$\text{coſ.}(x + \Delta x) = \text{coſ. } x - A \cdot \Delta x \text{ ſin. } x + \text{&c.}$$

Hence the derived function, or differential co-efficient of ſin. x will be $A \cdot$ coſ. x, and that of coſ. x will be $-A \cdot$ ſin. x.

The co-efficient A is an unknown conſtant quantity, to be determined by the nature of the circle.

Having thus found the firſt differential co-efficients, the others may be found in the ſame manner; thus, $D \cdot$ ſin. x being A coſ. x, $D^2 \cdot$ ſin. x will be $-A^2$ ſin. x, and $D^3 \cdot$ ſin. x will be $-A^2$ coſ. x.

Therefore,

Therefore, in general, if y or $\varphi x = \text{fin. } x$

$\frac{dy}{dx} = A \cdot \text{cof. } x$; $\frac{d^2y}{dx^2} = A^2 \cdot \text{fin. } x$; $\frac{d^3y}{dx^3} = -A^3 \text{ cof. } x$ &c.

Making theſe ſubſtitutions in the expanded ſeries for $\varphi(x + \Delta x)$

$$\text{fin. } (x + \Delta x) = \text{fin. } x + A \cdot \Delta x \cdot \text{cof. } x - \frac{A^2 \Delta x^2}{2} \text{ fin. } x - \frac{A^3 \Delta x^3}{2 \cdot 3} \text{ cof. } x + \frac{A^4 \Delta x^4}{2 \cdot 3 \cdot 4} \text{ fin. } x + \text{ &c.}$$

In the ſame manner, if y or $\varphi x = \text{cof. } x$

$\frac{dy}{dx} = -A \text{ fin. } x$; $\frac{d^2y}{dx^2} = -A^2 \text{ cof. } x$; $\frac{d^3y}{dx^3} = A^3 \text{ fin. } x$; $\frac{d^4y}{dx^4} = A^4 \text{ cof. } x$, &c.

And theſe ſubſtitutions will give

$$\text{cof. } x + \Delta x = \text{cof. } x - A \cdot (\Delta x) \text{ fin. } x - \frac{A^2 (\Delta x)^2}{2} \text{cof. } x + \frac{A^3 (\Delta x)^3}{2 \cdot 3} \text{ fin. } x + \frac{A^4 (\Delta x)^4}{2 \cdot 3 \cdot 4} \text{ cof. } x - \text{ &c.}$$

Let $P = A \cdot \Delta x - \frac{A^3 (\Delta x)^3}{2 \cdot 3} + \frac{A^5 (\Delta x)^5}{2 \cdot 3 \cdot 4 \cdot 5}$ &c.

$$Q = 1 - \frac{A^2 (\Delta x)^2}{2} + \frac{A^4 (\Delta x)^4}{2 \cdot 3 \cdot 4} - \frac{A^6 (\Delta x)^6}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} + \text{ &c.}$$

Then $\text{fin. } (x + \Delta x) = Q \text{ fin. } x + P \text{ cof. } x$

$\text{cof. } (x + \Delta x) = Q \text{ cof. } x - P \text{ fin. } x$

Hence $\text{fin. } \Delta x = P$, and $\text{cof. } \Delta x = Q$.

Thus, whatever be the angle Δx

$$\text{fin. } \Delta x = A \cdot \Delta x - A^3 \frac{(\Delta x)^3}{2 \cdot 3} + A^5 \frac{(\Delta x)^5}{2 \cdot 3 \cdot 4 \cdot 5} - \text{ &c.}$$

$$\text{cof. } \Delta x = 1 - A^2 \frac{(\Delta x)^2}{2} + A^4 \frac{(\Delta x)^4}{2 \cdot 3 \cdot 4} - \text{ &c.}$$

It is evident that theſe ſeries are both of them convergent, provided the angle Δx is ſuch that $A \cdot \Delta x$ be leſs or equal to unity; in that caſe

$$\text{fin. } \Delta x \angle A \cdot \Delta x \text{ and } \rangle A \cdot \Delta x - \frac{A^3 \cdot \Delta x^3}{2 \cdot 3}$$

for the terms having alternate ſigns and continually diminiſhing, the ſum of the ſecond and third of the fourth and fifth, &c. will be all negative, and on the contrary, the ſums of the third and fourth, the fifth and ſixth, &c. will be all poſitive.

Now by the theorem of Archimedes, we may aſſume, that the ſine is always leſs than the arc, and the tangent always greater. Hence

$$\text{fin. } \Delta x < \Delta x, \text{ and } \frac{\text{fin. } \Delta x}{\text{cof. } \Delta x} > \Delta x$$

but $\text{cof. } \Delta x = \sqrt{1 - \text{fin.}^2 \Delta x}$

therefore $\frac{\text{fin. } \Delta x}{\sqrt{1 - \text{fin.}^2 \Delta x}} > \Delta x$; $\text{fin.}^2 \Delta x > (\Delta x)^2 \cdot (1 - \text{fin.}^2 \Delta x)$

$$\text{hence } \text{fin. } \Delta x > \frac{\Delta x}{\sqrt{1 + (\Delta x)^2}}$$

And from the property of the circle

$$\text{fin. } \Delta x < \Delta x, \text{ and } > \frac{1}{\sqrt{1 + (\Delta x)^2}}$$

If the angle Δx be taken leſs than 90°, and ſo ſmall that $A \cdot \Delta x$ be leſs than unity, then

$$\text{fin. } \Delta x < A \cdot \Delta x, \text{ and } > \frac{1}{\sqrt{1 + (\Delta x)^2}}$$

and conſequently $A \cdot \Delta x > \frac{1}{\sqrt{1 + \Delta x^2}}$ and $A > \frac{1}{\sqrt{1 + (\Delta x)^2}}$; likewiſe $\text{fin. } \Delta x > A \cdot \Delta x - \frac{A^3 \Delta x^3}{2 \cdot 3}$ and $< \Delta x$, and conſequently $A \Delta x - \frac{A^3 \cdot (\Delta x)^3}{2 \cdot 3} < \Delta x$ and $A - \frac{A^3 (\Delta x)^3}{2 \cdot 3} < \Delta x$, or $A < 1 + \frac{A^3 (\Delta x)^3}{2 \cdot 3}$.

As theſe conditions muſt take place however ſmall Δx, it reſults that A cannot be leſs than unity, for if $A < 1$ we ſhould have $\frac{1}{A} > 1$; but the condition $A > \frac{1}{\sqrt{1 + (\Delta x)^2}}$ gives $\frac{1}{A} < \sqrt{1 + (\Delta x)^2}$; therefore if $\frac{1}{A}$ ſurpaſſes unity by ever ſo ſmall a quantity, it will be always poſſible to take Δx ſuch, that $\sqrt{1 + (\Delta x)^2} < \frac{1}{A}$, whereas this quantity muſt always be $> \frac{1}{A}$.

It appears from the ſecond condition that A cannot be greater than unity, for if A ſurpaſſes unity by ever ſo ſmall a quantity, it will always be poſſible to take Δx ſo ſmall, that $1 + \frac{A^3 (\Delta x)^3}{2 \cdot 3} < A$, whereas we ſhould always have $1 + \frac{A^3 (\Delta x)^3}{2 \cdot 3} > A$.

Therefore ſince A can neither be leſs or greater than unity, it follows that $A = 1$.

Therefore the derived function of the differential co-efficient of $\text{fin. } x$ is ſimply $= \text{cof. } x$;

and that of $\text{cof. } x = -\text{fin. } x$; x denoting any angle whatever, that is, an arc of a circle whoſe rad. $= 1$. Therefore for any angle Δx

$$\text{fin. } \Delta x = \Delta x - \frac{(\Delta x)^3}{2 \cdot 3} + \frac{(\Delta x)^5}{2 \cdot 3 \cdot 4 \cdot 5} + \frac{(\Delta x)^7}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7} + \text{ &c.}$$

$$\text{cof. } \Delta x = 1 - \frac{(\Delta x)^2}{2} + \frac{(\Delta x)^4}{2 \cdot 3 \cdot 4} + \frac{(\Delta x)^6}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} + \text{ &c.}$$

which well known formulæ were diſcovered by Newton. In the ſame manner as the ſine and co-ſine are functions of the angle; the angle itſelf may be conſidered as a function of the ſine or co-ſine and its differential found.

Let $\varphi x z =$ angle of ſine x; then $\text{fin. } \varphi x = x$; let x become $x + \Delta x$, and ſuppoſe

$$\frac{dz}{dx} \cdot \Delta x + \frac{d^2 z}{2 \cdot dx^2} \cdot (\Delta x)^2 + \frac{d^3 x}{2 \cdot 3 \cdot dx^2} (\Delta x)^3 + \text{ &c.}$$

$= n$; then $\text{fin. } (\varphi x + n) = x + \Delta x = \text{fin. } (\varphi x) \text{ cof. } n + \text{cof. } (\varphi x) \cdot \text{fin. } n$; and $\text{fin. } (\varphi x) = x$; $\text{cof. } (\varphi x) = \sqrt{1 - \text{fin.}^2 \varphi x} = \sqrt{1 - x^2}$.

Moreover by the above formulæ

$$\text{fin. } n = n - \frac{n^3}{2 \cdot 3} + \text{ &c. and } \text{cof. } n = n - \frac{n}{2} + \text{ &c.}$$

Making

Making therefore theſe ſubſtitutions, and reſtoring the value of n, we ſhall have

$$x + \Delta x = x + \Delta x \sqrt{(1 - x^2)} \cdot \frac{dz}{dx} + \frac{(\Delta x)^2}{2}$$

$\left(\sqrt{(1-x)} \cdot \frac{d^2 z}{dx^2}\right)$ + &c. which, by comparing the firſt terms affected with Δx, gives

$$1 = \sqrt{(1 - x^2)} \cdot \frac{dz}{dx}, \text{ from which reſults}$$

$$\frac{dz}{dx} = \frac{1}{\sqrt{1 - x^2}}$$

The compariſon of the other terms will give the ſecond and third, &c. differentials.

In like manner, if

φx = angle cof. x; x = cof. (φx)

for x put $x + \Delta x$, and $\varphi x + n$ for φx; then

$x + \Delta x$ = cof. $(\varphi x + n)$ = cof. (φx) . cof. n − ſin. (φx) ſin. n; and cof. $(\varphi x) = x$, and ſin. $(\varphi x) = \sqrt{(1 - \text{cof.}^2 (\varphi x))} = \sqrt{1 - x^2}$.

Making theſe ſubſtitutions, and putting for ſin. n . cof. n, their values in ſeries, $n - \frac{n^3}{2 \cdot 3}$ &c.

and $1 - \frac{n^2}{2}$ + &c. as in the former example; then

$$x + \Delta x = x - \Delta x \sqrt{(1 - x^2)} \frac{dz}{dx} - \frac{(\Delta x)^2}{2}$$

$\left(\sqrt{(1-x^2)} \frac{d^2 z}{dx}\right)$ + &c. which gives $1 = -\sqrt{(1-x^2)}$ $\frac{dz}{dx}$ and $\frac{dz}{dx} = -\frac{1}{\sqrt{1-x}}$.

Since therefore x being the ſine of an angle, $\sqrt{1-x^2}$ is the coſine, and x being the coſine, $\sqrt{1-x^2}$ is the ſine; it follows from the above inveſtigation, that the differential of an angle expreſſed by its ſine is equal to unity divided by its coſine, and the differential of an angle expreſſed by its coſine is equal to unity divided by its ſine, taken with a negative ſign.

On the uſe of differential Equations in the transformation of Functions —When the function of a variable quantity is preſented under two different forms, by equalling theſe expreſſions we obtain what is called an identical equation, becauſe of the identity of the value, and which muſt ſubſiſt independently of the variable quantity, that is, we may aſſign to the variable quantity x any value Δx whatever.

Let $\varphi x = 0$ be a ſimilar equation, then

$\varphi (x + \Delta x) = 0$, and

$\varphi x + D \varphi x . \Delta x + \overset{D^2}{c} \varphi x . (\Delta x)^2 + \text{&c.} = 0$;

and therefore ſeparately

$\varphi x = 0$; $D \varphi x = 0$; $\overset{D^2}{c} \varphi x = 0$, &c.

The ſame equation therefore ſubſiſts between the differentials of any order whatever,

Suppoſe now an equation, as $\varphi (x,y) = 0$ between two variable quantities x and y, in which y muſt be ſome function of x, then from what has been ſaid it follows that the ſame equation ſubſiſts between all the differential equations of any order whatever.

And in general, firſt and ſecond differential equations, &c. are ſo termed, not only when they are directly deduced from the primitive equation, but when they conſiſt of any combination of the differential and primitive equation; thus, when the primitive equation contains x and y, the firſt differential equation will contain x, y, and $\frac{dy}{dx}$, the ſecond, y, x, $\frac{dy}{dx}$, $\frac{d^2 y}{dx^2}$ and ſo on; and by what has preceded, one of thoſe ſyſtems of equations may always be transformed into another.

To illuſtrate the uſe of theſe equations in the transformation of functions by an example, let us take the caſe of ſin. x, and coſ. x, the differentials of which have been already inveſtigated.

Let y = ſin. x; z = coſ. x; then

$\frac{dy}{dx}$ = coſ. x, and $\frac{dz}{dx} = -$ ſin. x, conſequently

$\frac{dy}{dx} = z$, and $\frac{dz}{dx} = -y$.

If we multiply the firſt of theſe equations by $\sqrt{-1}$, and then add it to the ſecond, $\frac{dz}{dx} + \frac{dy}{dx}\sqrt{-1} = z\sqrt{-1}$

$-y = (z + y\sqrt{-1})\sqrt{-1}$;

hence the equation

$$\frac{\frac{dz}{dy} + \frac{dy}{dx}\sqrt{-1}}{z + y\sqrt{-1}} = \sqrt{-1}$$

Now from what has preceded, it appears that if p be any function of x, $\frac{\frac{dp}{dx}}{p}$ is the differential of the log. p; therefore log. $(z + y\sqrt{-1}) = x\sqrt{-1} + k$ will be the primitive equation from which the preceding one may be conſidered as derived; k is an arbitrary conſtant quantity to be determined by the nature of the functions y and z, conformably to the method of what we call finding fluents.

For this purpoſe we may obſerve that on making $x = 0$, we have ſin. $x = 0$, and coſ. $x = 1$; therefore $y = 0$, $z = 1$.

It is therefore neceſſary that the equation above found ſatisfies theſe ſuppoſitions; but in this caſe it becomes log. $1 = k$, and ſince log. $1 = 0$; $k = 0$; the equation therefore will ſimply be log. $(z + y\sqrt{-1}) = x\sqrt{-1}$; hence $z + y\sqrt{-1} = e^{x\sqrt{-1}}$; e being the number whoſe Naperian log. is unity.

For y and z ſubſtitute their values ſin. x, coſ. x, and we obtain this remarkable formula

$$\text{coſ. } x + \text{ſin. } x\sqrt{-1} = e^{x\sqrt{-1}}$$

which from the double ſignification of the radical $\sqrt{-1}$ gives equally

$$\text{coſ. } x - \text{ſin. } x\sqrt{-1} = e^{x\sqrt{-1}}$$

and theſe equations combined are ſufficient to determine the values of ſin. x and coſ. x. For by adding them or ſubtracting them we have

$$\text{coſ. } x = \frac{e^{x\sqrt{-1}} + e^{-x\sqrt{-1}}}{2}$$

$$\text{ſin. } x = \frac{e^{x\sqrt{-1}} - e^{-x\sqrt{-1}}}{2}$$

in

in which the ſine and coſine is expreſſed in terms of imaginary exponentials, which may be conſidered as one of the moſt curious analytical diſcoveries of the laſt century.

Theſe formulæ may likewiſe be derived immediately from the ſeries already given which expreſs the functions ſin. x, coſ. x, e^x. It is in this manner that Euler has given them in vol. viſ. of the Miſcellanea Berolinenſia.

The expreſſion for the value of arcs in imaginary logarithms was diſcovered by John Bernouilli, who has given it in the Memoirs of the Academy of Sciences for 1702. He obtained it by integrating by means of logarithms the elements of the arc expreſſed in terms of the tangent in the ſame manner as Leibnitz had found the ſeries which expreſſes the arc by the tangent, by integrating the ſame element in ſeries.

The equation coſ. x + ſin. $x\sqrt{-1} = e^{x\sqrt{-1}}$, where the radical $\sqrt{-1}$ may equally have the ſign + or −, forms the baſis of the theory of the calculation of angles; for by multiplying this equation by the ſimilar equation coſ. y + ſin. $y\sqrt{-1} = e^{y\sqrt{-1}}$ we have $(\text{coſ. } x + \text{ſin. } x\sqrt{-1})\ (\text{coſ. } y + \text{ſin. } y\sqrt{-1} = e^{(x+y)\sqrt{-1}}$, and ſubſtituting in the ſame equation $x + y$ in the place of x,

$\text{coſ. } (x+y) + \text{ſin. } (x+y)\sqrt{-1} = e^{(x+y)\sqrt{-1}}$;

comparing and expanding the product,

coſ. x . coſ. y − ſin. x . ſin. y + (coſ. x . ſin. y + coſ. y ſin. x) $\sqrt{-1}$ = coſ. $(x+y)$ + ſin. $(x+y)\sqrt{-1}$;

and as this equation muſt ſubſiſt for the two ſigns of $\sqrt{-1}$ it follows that ſeparately

coſ. x . coſ. y − ſin. x . ſin. y = coſ. $(x+y)$
coſ. x ſin. y + ſin. x coſ. y = ſin. $(x+y)$

which formulæ may be demonſtrated geometrically, and form the baſis of the theory of angles.

In addition to the following inveſtigation of what is uſually called the inverſe method of fluxions, as given by Mr. Woodhouſe, the reader is referred to the article FLUENT, the ſubſtance of which is likewiſe taken from the works of this learned analyſt.

In contradiſtinction to the direct operations of multiplication and involution, diviſion and evolution are called reverſe operations; but when all the reſults of theſe operations are comprehended under a common formula ($\varphi x + \mathrm{D}\,\varphi x \,.\, \Delta x$ + &c.), or expreſſed by a general method, it is commodious to conſider the latter method by which algebraic functions are expanded, and any term aſſigned as a direct method; and the method by which, from any term of an expanded function, we aſcend to the original function, a reverſe method.

On the former method depends the *differential calculus*, by which from φx the ſecond, third, &c. terms of $\varphi(x + \mathrm{d}x)$ expanded, are aſſigned; on the reverſe depends the *integral calculus*, by which from $\mathrm{X}\,.\,\mathrm{d}x$, $\mathrm{X}'\,.\,\mathrm{d}x^2$, &c. the functions fx, $f'x$, of which functions $\mathrm{X}\,.\,\mathrm{d}x$, $\mathrm{X}'\,.\,\mathrm{d}x^2$ &c. are the firſt, ſecond differentials, &c. or are the ſecond, third, &c. terms of $f(x + \mathrm{d}x)$, $f'(x + \mathrm{d}x)$ &c. expanded, are to be aſſigned. The integral calculus is unable, however, in all caſes, to aſſign the original or primitive functions of fx, from which a differential $\mathrm{X}\,\mathrm{d}x$ is derived; its rules (like thoſe for the extraction of roots) are eſtabliſhed by inſpection of the direct proceſs, by which, from primitive functions, differentials are obtained; thus $\mathrm{d}(x^m) = m x^{m-1}\,.\,\mathrm{d}x$, ∴ from $m x^{m-1}\,.\,\mathrm{d}x$ we may aſcend to x^m by this proceſs; increaſe the index $(m-1)$ of the power of the variable quantity (x) in the differential $(m x^{m-1}\,.\,\mathrm{d}x)$ by 1; and then divide the differential by the index ſo increaſed (m), and by the differential $(\mathrm{d}x)$ of the variable quantity (x): the reſult of this proceſs is the integral or primitive function (x^m). Let d^{-1} be the ſymbol of the operation by which the integral is obtained, (the reverſe of that operation which d indicates),

then $\mathrm{d}^{-1}(m x^{m-1}\,\mathrm{d}x) = x^m$, or $\mathrm{d}^{-1}\,\mathrm{d}(x^m) = x^m$,

Again, $\mathrm{d}^{-1}(x^{\frac{m}{n}}\,\mathrm{d}x) = \dfrac{x^{\frac{m}{n}+1}}{\frac{m}{n}+1}$; and $\mathrm{d}^{-1}(x^{r-1} = \dfrac{x^r}{r\,.\,\mathrm{d}x}$

Again, from what has preceded it appears, that if p be a function of x, the differential of $\varphi p = \mathrm{D}\,\varphi p\,.\,\mathrm{d}p$ or $= \dfrac{\mathrm{d}\,\varphi p}{\mathrm{d}p}\,.\,\mathrm{d}p$; hence to find the integral or primitive function of ſuch a differential as $\mathrm{D}\,\varphi p\,.\,\mathrm{d}p$, we have only to find the function of which $\mathrm{D}\,\varphi p$ is the differential co-efficient: but it muſt be obſerved, that the integral of a differential, as $fp\,.\,\mathrm{d}q$ (q a function of x) can only be found under certain conditions: for if $\mathrm{F}p$ be the function of which fp is the differential co-efficient, then $fp = \dfrac{\mathrm{d}\,\mathrm{F}p}{\mathrm{d}p}$

$\therefore fp\,.\,\mathrm{d}q = \dfrac{\mathrm{d}\,\mathrm{F}p}{\mathrm{d}q}\,.\,\mathrm{d}q$ ∴ if $\mathrm{d}p = a\,\mathrm{d}q$, a an invariable quantity, the integral can be found: but if $\mathrm{d}p$ does not $= \mathrm{d}q$, the integral cannot be found, at leaſt not immediately: for inſtance, let $fp\,.\,\mathrm{d}q = (a + bx + cx^2)^m\,.\,(b\,\mathrm{d}x + 2cx\,\mathrm{d}x)$, then $p = a + bx + cx^2$, and ∴ $\mathrm{d}p = b\,\mathrm{d}x + 2cx\,\mathrm{d}x$; but $\mathrm{d}q = b\,\mathrm{d}x + 2cx\,\mathrm{d}x$, conſequently the integral can be found $= \dfrac{(a + bx + cx^2)^{m+1}}{m+1}$;

again let $fp\,.\,\mathrm{d}q = (a + bx^n)^m\,.\,x^r\,\mathrm{d}x$, then $p = a + bx^n$, and $\mathrm{d}p = nbx^{n-1}\,\mathrm{d}x$, and $\mathrm{d}q = x^r\,\mathrm{d}x$, conſequently the integral cannot be found (at leaſt not immediately) except $r = n - 1$, or except the index of the power of the variable quantity, without the vinculum, be leſs by unity than the index of the power of the variable quantity under the vinculum;

again, if $fp\,.\,\mathrm{d}q = (a + bx^n + cx^r)^m\,(nbx^t + rcx^t)\,\mathrm{d}x$, ∴ $p = a + bx^n + cx^n$ and ∴ $\mathrm{d}p = nbx^{t-1}\,\mathrm{d}x + rcx^{r-1}\,\mathrm{d}x$; but $\mathrm{d}q = nbx^t\,\mathrm{d}x + rcx^t\,\mathrm{d}x$, conſequently the integral of $fp\,.\,\mathrm{d}q$ cannot be aſſigned (at leaſt not immediately) except $t = n - 1$, and $s = r - 1$; again, if $fp\,.\,q = e^{x^2}\,.\,x\,\mathrm{d}x$, $p = x^2$, $fp = e^{x^2}$, $\mathrm{d}p = 2x\,\mathrm{d}x$, but $\mathrm{d}q = x\,\mathrm{d}x$, conſequently the integral of e^{x^2}, $x\,\mathrm{d}x$ can be found $\left(= \dfrac{e^{x^2}}{2}\right)$

The integrals of $a^x\,.\,\mathrm{d}x$, $e^x\,.\,\mathrm{d}x$, are $\dfrac{a^x}{\mathrm{A}}$, e^x, and are obtained on the ſame grounds as the integrals of $x^{n-1}\,\mathrm{d}x$, $(a + bx^n)^m\,.\,x^{n-1}\,\mathrm{d}x$, &c. are; that is, by inſpection of the reſults, which the operation of *differentiation* performed on known functions, gives

$\mathrm{d}(a + bx) = b\,\mathrm{d}x$, $\mathrm{d}(a' + bx) = b\,\mathrm{d}x$,
$\mathrm{d}(a'' + bx) = b\,\mathrm{d}x$, &c.

Hence, reverſely, $\mathrm{d}^{-1}(b\,\mathrm{d}x) = a + bx$, or $= a' + bx$, or $= a'' + bx$, or = &c.

Theſe conſtant quantities a, a', a'', &c. are called *corrections*, and in integrating ſuch an expreſſion as $b\,\mathrm{d}x$, which of the corrections a, a', a'' is to be uſed, muſt be determined

by

by the nature of the inveſtigation, in which ſuch an expreſſion as $b\,\mathrm{d}\,x$ occurs.

Let $x^2 - 2ay + y^2 = 0$, then $x\,\mathrm{d}\,x - a\,\mathrm{d}\,y + y\,\mathrm{d}\,y = 0$; but from the original equation $a = \frac{x^2 + y^2}{2y}$; and ſubſtituting

$$x\,\mathrm{d}\,x - \frac{x^2 + y^2}{2y}\,\mathrm{d}\,y + y\,\mathrm{d}\,y = 0;$$

$$\text{or } 2y\,x\,\mathrm{d}\,x - x^2\,\mathrm{d}\,y + y^2\,\mathrm{d}\,y = 0;$$

in which differential equation the arbitrary quantity a does not appear.

In like manner, if the equation were $x^2 - 2ay + by^2 = 0$, the firſt differential equation would be $x\,\mathrm{d}\,x - a\,\mathrm{d}\,y + b\,y\,\mathrm{d}\,y = 0$; the ſecond differential equation

$$x\,\mathrm{d}^2 x + \mathrm{d}\,x^2 - a\,\mathrm{d}^2 y + by\,\mathrm{d}^2 y + b\,\mathrm{d}\,y^2 = 0;$$

from which three equations the two arbitrary quantities a and b may be eliminated, and the reſulting differential equation will be of the ſecond order, containing neither a nor b.

Generally, ſuppoſe $\varphi\,(x, y) = 0$, an equation between x and y to contain arbitrary quantities a, b, c, &c. then theſe arbitrary quantities will be the ſame in the firſt, ſecond, &c. differential equations deſignated by $\mathrm{d}\,(\varphi\,(x, y)) = 0$, $\mathrm{d}^2\,(\varphi\,(x, y)) = 0$, $\mathrm{d}^3\,(\varphi\,(x, y)) = 0$, &c. Now from $\varphi\,(x, y) = 0$, and $\mathrm{d}\,(\varphi\,(x, y)) = 0$, a conſtant quantity as a, may be eliminated, and the reſulting equation will be a differential equation of the firſt order, between x, y, $\frac{\mathrm{d}\,y}{\mathrm{d}\,x}$, containing a conſtant arbitrary quantity, leſs than the original equation; again, from $\varphi\,(x, y) = 0$, $(\varphi\,(x, y)) = 0$, $\mathrm{d}^2\,(\varphi\,(x, y)) = 0$, two conſtant quantities a and b may be eliminated, and the reſulting equation will be of the ſecond order between x, y, $\frac{\mathrm{d}\,y}{\mathrm{d}\,x}$, $\frac{\mathrm{d}^2 y}{\mathrm{d}\,x^2}$, and containing two conſtant quantities leſs than the original or primitive equation, and ſo on.

Hence, ſince a differential equation of the firſt order may contain a conſtant quantity leſs than the primitive equation, and ſince a differential equation of the ſecond order may contain two conſtant quantities leſs than the primitive equation, &c.; reverſely, a primitive equation ought to have one more conſtant quantity than the differential equation of the firſt order, two more conſtant quantities than the differential equation of the ſecond order, and ſo on; and it cannot contain more, ſince if you ſuppoſe $\varphi\,(x, y)$ to contain three more than the differential equation of the ſecond order, it is plain that from $\varphi\,(x, y) = 0$, $\mathrm{d}\,(\varphi\,(x, y)) = 0$, $\mathrm{d}^2\,(\varphi\,(x, y)) = 0$, no more than two can be eliminated, conſequently one muſt remain in the equation betwecn x, y, $\frac{\mathrm{d}\,y}{\mathrm{d}\,x}$, $\frac{\mathrm{d}^2 y}{\mathrm{d}\,x^2}$, &c.

Theſe conſtant quantities are arbitrary, that is, they are to be expreſſed by general characters; what their values are to be muſt depend on the nature of the ſubject inveſtigated.

It does not neceſſarily happen that the primitive equation has one more conſtant quantity than the differential equation, or two more conſtant quantities than the ſecond differential equation; only as it may have, in taking the integral, you aſſign the primitive equation in its moſt general form; and if, inſtead of arbitrary quantities, it really has only $n - n'$, then the proceſs for determining the value of the arbitrary quantities will ſhew, that n' ſuch are equal to 0; hence no error or ambiguity can ariſe from introducing into the primitive equation by the proceſs of integration as many conſtant arbitrary quantities as it *can* have more than the differential equation.

Thus ſuppoſe $\frac{y\,\mathrm{d}^2 y}{\mathrm{d}\,x^2} + \frac{\mathrm{d}\,y^2}{\mathrm{d}\,x^2} - \frac{x\,\mathrm{d}^2 y}{\mathrm{d}\,x^2} - \frac{2\,\mathrm{d}\,y}{\mathrm{d}\,x} + 1 = 0$ (y a function of x), then integrating $\frac{y\,\mathrm{d}\,y}{\mathrm{d}\,x} - \frac{x\,\mathrm{d}\,y}{\mathrm{d}\,x} - y + x = a$,

$$\text{or } y\,\mathrm{d}\,y - x\,\mathrm{d}\,y - y\,\mathrm{d}\,x + x\,\mathrm{d}\,x = a\,\mathrm{d}\,x.$$

Again, integrating $\frac{y^2}{2} - xy + \frac{x^2}{2} = ax + b$.

Now the arbitrary conſtant quantities a and b are to be determined by the nature of the ſubject of inveſtigation; ſuppoſe it ſuch, that when $x = 0$, $y = 0$, and that when $x = r$, y alſo $= r$, hence putting $x = 0$, it appears that b muſt $= 0$, $\therefore$ equation is reduced to $y^2 - 2xy + x^2 = 2ax$, put $x = r$, then $y = r$, $\therefore r^2 - 2r^2 + r^2 = 2ar$, or $0 = 2ar$, $\therefore a = 0$, and the primitive equation is $x^2 - 2xy + y^2 = 0$; hence no error can ariſe from introducing the arbitrary conſtant quantities a and b; but in aſſigning the general form of the primitive equation, they muſt both be introduced, ſince if the conditions by which they are to be determined are altered, one or both may be retained.

It has appeared that differential equations of the firſt order have one arbitrary conſtant quantity leſs than the primitive equation; that differential equations of the ſecond order have two leſs, and ſo on; ſuppoſe now that from the equations $\varphi\,(x, y) = 0$, $\mathrm{d}\,(\varphi\,(x, y)) = 0$, two differential equations of the firſt order are formed, the one containing a conſtant quantity a, the other a conſtant quantity b; let the firſt equation be $\mathrm{d}\,(\mathrm{A}) = 0$, the ſecond $\mathrm{d}\,(\mathrm{B}) = 0$; from $\mathrm{d}\,(\mathrm{A}) = 0$, and $\mathrm{d}\,(\mathrm{A}) = 0$, eliminate a, from $\mathrm{d}^2\,(\mathrm{B}) = 0$, and $\mathrm{d}\,(\mathrm{B}) = 0$, eliminate b, then the two reſulting differential equations ought to agree with one another, and with the differential equation of the ſecond order $(\mathrm{d}^2\,(\mathrm{X}))$, obtained by eliminating a and b from the three equations $\varphi\,(x, y) = 0$, $\mathrm{d}\,\varphi\,(x, y) = 0$, $\mathrm{d}^2\,\varphi\,(x, y) = 0$.

Hence a differential equation of the ſecond order may be derived from two differential equations of the firſt order, each containing one additional arbitrary conſtant quantity.

Hence, if for a differential equation of the ſecond order $(\mathrm{d}^2\,\mathrm{U} = 0)$, we find two differential equations of the firſt order, which ſatisfy the equation $\mathrm{d}^2\,\mathrm{U} = 0$, to wit $\mathrm{d}\,\mathrm{X} = 0$, containing an arbitrary conſtant quantity a, and $\mathrm{d}\,\mathrm{Y} = 0$, containing an arbitrary conſtant quantity b, by eliminating $\frac{\mathrm{d}\,y}{\mathrm{d}\,x}$ from the equations $\mathrm{d}\,\mathrm{X} = 0$, $\mathrm{d}\,\mathrm{Y} = 0$, there will reſult an equation between x and y, containing the two arbitrary quantities a and b, and which is the primitive or integral equation of $\mathrm{d}^2\,\mathrm{U} = 0$.

Having thus given an abſtract of the principles of analytical calculation, we ſhall now ſhew in what manner Mr. Woodhouſe applies them to ſuch inveſtigations as are uſually performed by the method of fluxions.

Inveſtigation of the Property of Curve Lines.—The curve lines, the properties of which are to be inveſtigated, are not ſuch as are generated by mechanical deſcription, but ſuch as are defined by equation, and having no exiſtence independant of what they receive from arbitrary appointment; and conſequently in deducing their properties, recourſe is to be had to the analytical expreſſions, of which

which, under certain conditions, the curves are to be made the repreſentatives.

In a ſtraight line, to be called the line of the abſciſſas, from a certain point, let a line, arbitrarily taken, be called the abſciſſa, and be denoted by x: at the ſeveral points correſponding to the different values of x, let ſtraight lines be continually drawn, making a certain angle with the line of the abſciſſas; theſe ſtraight lines are to be called ordinates, and the line or figure in which their extremities are continually found, is generally to be called a curve line.

The values of theſe are to be determined by an equation between y and x: thus $y = \varphi x$, and if x be increaſed by Δx, then by the preceding methods $y + \Delta y$ becomes $\varphi(x + \Delta x)$ or

$$y + \frac{dy}{dx} \cdot \Delta x + \frac{d\,y}{1 \cdot 2 \cdot dx} (\Delta x)^2 + \frac{d\,y}{1 \cdot 2 \cdot 3 \cdot dx} (\Delta x)^3$$

+ &c. and ſince the value of $y + \Delta y$ is to be calculated, ſuch ſeries muſt converge. For greater ſimplicity in the following demonſtrations the ordinates are ſuppoſed to be rightly applied.

According to the above definition of a curve line, the locus of the extremities of the ordinates muſt, in one inſtance, be a ſtraight line; for the function φx being of the form $ax + b$ (a and b conſtant quantities) the extremities of all the ordinates will be found in a ſtraight line.

There are certain propoſitions, it is known, relative to curves, which have not been ſatisfactorily eſtabliſhed, and the want of perſpicuity and accuracy in the demonſtrations of ſuch propoſitions is attributed to the definition that has been given of a curve line which is negative, making a curve to be that of which no portion is a ſtraight line. Admitting, however, the foregoing definition of a curve line, which merely ſtates it to be locus of the extremities of the ordinates, the negative definition will become a property, and capable of being demonſtrated. Thus, let the interval between any two ordinates be Δx, then y being one ordinate, the next (y') ſeparated by an interval Δx, is $y + \mathrm{D} \cdot y \cdot \Delta x + \overset{c}{\mathrm{D}}{}^2 \cdot y\,(\Delta x)^2 + \overset{c}{\mathrm{D}}{}^3 \cdot y\,(\Delta x)^3 +$ &c. Again, the value of another ordinate between y and $y + \Delta y$ at an interval δx ($\delta x \angle \Delta x$), is $y + \mathrm{D} \cdot y \cdot \delta x + \overset{c}{\mathrm{D}}{}^2 \cdot y \cdot (\delta x)^2 +$ &c. But if the line joining the extremities of y and y' were a ſtraight line, then $y + \mathrm{D} \cdot y \cdot \delta x + \overset{c}{\mathrm{D}}{}^2 \cdot y \cdot (\delta x)^2 +$ &c. ought to $= y + \frac{\delta x}{\Delta x}$, or $y + \mathrm{D} \cdot y \cdot \delta x + \overset{c}{\mathrm{D}}{}^2 \cdot y \cdot \delta x \cdot \Delta x +$ &c. which it evidently does not, except $\overset{c}{\mathrm{D}}{}^2 \cdot y$, $\overset{c}{\mathrm{D}}{}^3 \cdot y$, &c. $= 0$; that is, it does not, the caſe of the curve belonging to an equation, as $y = ax + b$ being excluded.

In order to prepare the way for the demonſtrations relative to tangents, radii of curvature, lengths of curve lines, &c. it is neceſſary to eſtabliſh this propoſition, namely, that in the ſeries $\varphi x + \mathrm{D}\,\varphi x \cdot \Delta x + \overset{c}{\mathrm{D}}{}^2 \varphi x \cdot (\Delta x)^2 +$ &c.; Δx may be taken of ſuch a magnitude, that any term $\overset{c}{\mathrm{D}}{}^m \varphi x\,(\Delta x)^m$, ſhall be greater than the ſum of all the ſucceeding terms.

In the method of fluxions and of limits, I have already mentioned that this propoſition, or one equivalent to it, is required; for to prove that the limiting ratio of $1 : nx^{n-1} + \frac{n \cdot (n-1)}{1 \cdot 2} x^{n-2} \cdot \Delta x + \frac{n \cdot (n-1)\,(n-2)}{1 \cdot 2 \cdot 3} x^{n-3} \cdot (\Delta x)^2 +$ &c. is $1 : nx^{n-1}$, it is neceſſary to ſhew, that by diminiſhing Δx, the ratio may be brought nearer to the ratio $1 : nx^{n-1}$, than by any aſſignable quantity, and conſequently it is neceſſary to ſhew within what limits the magnitude of the rejectaneous quantity $\frac{n \cdot n-1}{1 \cdot 2} \cdot x^{n-2} \cdot \Delta x + \frac{\overline{n \cdot n-1} \cdot \overline{n-2}}{1 \cdot 2 \cdot 3} x^{n-3} \cdot (\Delta x)^2 +$ &c. is contained: φx being a function of x, when x is increaſed to $x + \Delta x$, $\varphi(x + \Delta x)$ expanded, becomes $\varphi x + \mathrm{D}\,\varphi x \cdot \Delta x +$ &c. $+ \overset{c}{\mathrm{D}}{}^n \varphi x \cdot (\Delta x)^n + \overset{c}{\mathrm{D}}{}^{n+1} \varphi x \cdot (\Delta x)^{n+1} +$ &c. Now if there are two ſucceſſive terms $\overset{c}{\mathrm{D}}{}^n \varphi x \cdot (\Delta x)^n$, $\overset{c}{\mathrm{D}}{}^{n+1} \varphi x \cdot (\Delta x)^{n+1}$ ſuch, that $\frac{\overset{c}{\mathrm{D}}{}^{n+1} \varphi x}{\overset{c}{\mathrm{D}}{}^n \varphi x}$ is greater than $\frac{\overset{c}{\mathrm{D}}{}^{s+1} \varphi x}{\overset{c}{\mathrm{D}}{}^s \varphi x}$, whatever s is, then Δx may be taken ſo ſmall, that any term, as $\mathrm{D}^m \varphi x \cdot (\Delta x)^m$, ſhall be greater than the ſum of all ſucceeding terms; for take $\Delta x \angle \frac{\overset{c}{\mathrm{D}}{}^n \varphi x}{2 \cdot \overset{c}{\mathrm{D}}{}^{n+1} \varphi x}$, then $\overset{c}{\mathrm{D}}{}^n \varphi x \cdot (\Delta x)^n + \overset{c}{\mathrm{D}}{}^{n+1} \varphi x \cdot (\Delta x)^{n+1}$ is $\angle \overset{c}{\mathrm{D}}{}^n \varphi x \cdot (\Delta x)^n\,(1 + \frac{1}{2})$.

Again, $\overset{c}{\mathrm{D}}{}^m \varphi x \cdot (\Delta x)^m + \overset{c}{\mathrm{D}}{}^{m+1} \varphi x \cdot (\Delta x)^{m+1}$ is $\angle \overset{c}{\mathrm{D}}{}^m \varphi x \cdot (\Delta x)^m\,(1 + \frac{1}{2})$, and ſo on, every term being leſs than half the preceding term, and conſequently, $\overset{c}{\mathrm{D}}{}^m \varphi x \cdot (\Delta x)^m + \overset{c}{\mathrm{D}}{}^{m+1} \varphi x \cdot (\Delta x)^{m+1} + \overset{c}{\mathrm{D}}{}^{m+2} \varphi x \cdot (\Delta x)^{m+2} +$ &c. is $\angle \mathrm{D}^m \varphi x \cdot (\Delta x)^m\,(1 + \frac{1}{2} + \frac{1}{2^2} + \frac{1}{2^3} +$ &c.); conſequently, $\angle \overset{c}{\mathrm{D}}{}^m \varphi x \cdot (\Delta x)^m \left(\frac{1}{1 - \frac{1}{2}}\right)$ or $\overset{c}{\mathrm{D}}{}^m \varphi x \cdot (\Delta x)^m \cdot 2$; and therefore the ſum of terms after $\overset{c}{\mathrm{D}}{}^m \varphi x \cdot (\Delta x)^m$ muſt be leſs than $\overset{c}{\mathrm{D}}{}^m \varphi x \cdot (\Delta x)^m$.

The propoſition then will be demonſtrated if it can be ſhewn that $\frac{\overset{c}{\mathrm{D}}{}^{n+1} \varphi x}{\overset{c}{\mathrm{D}}{}^n \varphi x}$, however great n, is never greater than a finite aſſignable quantity; and in order to aſcertain this point, reference muſt be made to the particular expreſſions comprehended under the generic ſymbol ϕx; for, concerning the abſolute magnitude of ſuch a ſymbol, nothing, it is plain, can abſtractedly be affirmed. Now φx repreſents x^m, a^x, $l \cdot x$, and may be made to repreſent functions compoſed of theſe by addition or ſubtraction. Firſt, with regard to x^m, $\overset{c}{\mathrm{D}}{}^n \varphi x \cdot (\Delta x)^n = \overset{c}{\mathrm{D}}{}^n x^m \cdot (\Delta x)^n = \frac{m \cdot (m-1)\,(m-2) \ldots (m-(n-1))}{1 \cdot 2 \cdot 3 \ldots n} x^{m-n}$ $(\Delta x)^n$, call this term T; then the ſucceeding term (T′) is $\mathrm{T} \cdot \frac{m-n}{n+1} \cdot \frac{\Delta x}{x}$, and conſequently $\frac{\overset{c}{\mathrm{D}}{}^{n+1} \varphi x}{\overset{c}{\mathrm{D}}{}^n \varphi x}$ is $\frac{m-n}{n+1} \cdot \frac{1}{x}$, which quantity, it is clear, does not exceed any aſſignable quantity, for it $< \frac{m+n}{n+1} \cdot \frac{1}{x}$, and whatever values of n (always an integer) be taken, the quantity, namely, $\frac{m+n}{n+1} \cdot \frac{1}{x}$ muſt always be contained between $\frac{m}{x}$ and $\frac{1}{x}$. Hence it follows, that Δx can be taken $< \frac{(n+1)\,x}{2 \cdot (m-n)^2}$ whatever

whatever n is, that is, can be taken leſs, taking the quantity at its leaſt.

Let now φx be repreſented by a^x, then $D^n \varphi x \cdot (\Delta x)^n$, or $\overset{D^n}{c}\, a^x \cdot (\Delta x)^n = \frac{A^n \cdot a^x}{1 \cdot 2 \cdot 3 \ldots\ldots n} \cdot (\Delta x)^n$ (T), and conſequently, next term (T') is, $T : \frac{A \cdot \Delta x}{n+1}, \ldots \frac{\overset{D^{n+1}}{c}\, \varphi x}{\overset{D^n}{c}\, \varphi x} = \frac{A}{n+1}$, and all the ſucceeding values of $\frac{A}{n+1}$ after the greateſt (A) continually decreaſe; hence in this caſe it is clear that Δx can be taken $< \frac{n+1}{2A}$ whatever n is, or can be taken leſs than the leaſt value of $\frac{n+1}{2A}$.

Let φx be repreſented by $l \cdot x$, or $L \cdot x$ (which functions belong to the equations $x = e^{l \cdot x}$, $x = a^{L \cdot x}$), then $\overset{D^n}{c}\, \varphi x \cdot (\Delta x)^n = \pm \frac{1}{A x^n} \cdot (\Delta x)^n$ (T), and conſequently, $\frac{D^{n+1} \varphi x}{\overset{D^n}{c}\, \varphi x} = \mp \frac{n}{(n+1)x}$, which quantity is always between $\frac{1}{2x}$ and $\frac{1}{x}$, and conſequently, in this caſe Δx can be taken $< \frac{(n+1)x}{2n}$ whatever n is, or can be taken leſs than the leaſt value of $\frac{(n+1)x}{2n}$.

Hence in φx it is true, that Δx can be taken of a magnitude ſuch, that any one term, as $\overset{D^m}{c}\, \varphi x \cdot (\Delta x)^m$, ſhall exceed the ſum of all the ſucceeding terms; and à fortiori ſhall exceed that ſum, the ſmaller Δx is.

Hence too, if the functions ſin. x, coſ. x, are comprehended by the ſymbol φx, the propoſition will ſtill be true, ſince the analytical expreſſions for theſe functions are formed by means of the exponential e^x.

The above propoſition is true of any ſeries, as $A + Bx + Cx^2 +$ &c. in which it can be ſhewn that $\frac{A_{m-1}}{A_m}$ is $> \frac{A_{r+1}}{A_r}$ whatever r is. Since, then, x (the arbitrary quantity) can be taken $< \frac{A_m}{2A_{m+1}}$, there are ſeries in which $\frac{A_{r+1}}{A_r}$ increaſes with the increaſe of r, and becomes infinite; but ſuch ſeries cannot occur in thoſe caſes wherein it is neceſſary to apply the propoſition, *viz.* that the arbitrary quantity (x or Δx) can be taken ſuch, that any one term ſhall exceed the ſum of all the ſucceeding terms.

For inſtance, if $A + Bx + Cx^2 +$ &c. be $1 + 1 \cdot 2 \cdot x + 1 \cdot 2 \cdot 3 \cdot x^3 +$ &c. then $\frac{A_{r+1}}{A_r} = \frac{1 \cdot 2 \cdot 3 \ldots r+1}{1 \cdot 2 \cdot 3 \ldots r} = r + 1$, which becomes infinite when r does, and therefore x cannot be taken $< \frac{1}{2 \cdot r + 1}$, but then ſuch a ſeries can never occur, for it would be abſurd to propoſe to deduce, for inſtance, the value of the ordinate of a curve from a ſeries which cannot be made to converge.

To determine the conditions under which the contact of curves takes place.

Let y be the ordinate of a curve, and let it be expreſſed by the function of the abſciſſa φx, then x becoming $x + \Delta x$, y becomes $y + \frac{dy}{dx} \cdot \Delta x + \frac{d^2 y}{1 \cdot 2 \cdot dx^2} \cdot (\Delta x)^2 +$ &c. let u be the ordinate of another curve, and let $u = ft$, t being an abciſſa taken in the ſame line of the abciſſas that x is in, then t becoming $t + \Delta t$, u becomes $u + \frac{du}{dt} \cdot \Delta t + \frac{d^2 u}{1 \cdot 2 \cdot dt^2} \cdot (\Delta t)^2 +$ &c. Suppoſe now the curves to have a common point, and for greater ſimplicity let each abſciſſa be meaſured from the ſame point, or let $t = x$, when $y = u$; if now $dy = du$, then the contact between the two curves is ſuch, that betweeen them no other curve drawn through the common point can paſs, except the differential (dv) of its ordinate (v) equals dy; for ſuppoſe it poſſible, then the ordinate v', diſtant from v by the interval Δx, $= v + \frac{dv}{dx} \cdot \Delta x + \frac{d^2 v}{1 \cdot 2 \cdot dx^2} \cdot (\Delta x)^2 +$ &c. and ſince the courſe of the curve, of which v is the ordinate, paſſes between the two other curves whoſe ordinates are y and u, the difference $y' - v'$, or $\Delta y - \Delta v$, ought to be leſs than $y' - u'$, or $\Delta y - \Delta u$, however ſmall Δx is, or $\left(\frac{dy}{dx} - \frac{dv}{dx}\right) \cdot \Delta x + \left(\frac{d^2 y}{1 \cdot 2 \cdot dx^2} - \frac{d^2 v}{1 \cdot 2 \cdot dx^2}\right) \cdot (\Delta x)^2 +$ &c. is $< \left(\frac{dy}{1 \cdot 2 \cdot dx^2} - \frac{d^2 u}{1 \cdot 2 \cdot dx^2}\right) \cdot (\Delta x)^2 + \left(\frac{d^3 y}{1 \cdot 2 \cdot 3\, dx^3} - \frac{du}{1 \cdot 2 \cdot 3\, dx^3}\right) \cdot (\Delta x)^3 +$ &c. (for by hypotheſis $\frac{dy}{dx} = \frac{du}{dx}$), however ſmall Δx is, or dividing by Δx, $\left(\frac{dy}{dx} - \frac{dv}{dx}\right) + a \cdot \Delta x + b \cdot (\Delta x)^2 +$ &c. is always $< a' \cdot \Delta x + b' \cdot (\Delta x)^2 +$ &c. (a, a', b, b', &c. being put for the co-efficients of the powers of Δx), however ſmall Δx is, which is evidently impoſſible, except $\frac{dy}{dx} = \frac{dv}{dx}$, or $dy = dv$; for the difference of the two expreſſions, to wit, $\left(\frac{dy}{dx} - \frac{dv}{dx}\right) + (a - a') \Delta x + (b - b') (\Delta x)^2 +$ &c. may be made poſitive by taking Δx ſuch, that $\frac{dy}{dx} - \frac{dv}{dx}$ ſhall be greater than $(a - a') \Delta x + (b - b') (\Delta x)^2 +$ &c. which, by what has preceded, is evidently poſſible; hence, between the courſes of the two curves in which the ordinates y, u, are equal, and the differentials of the ordinates, namely, dy, du, likewiſe equal, no other curve drawn through the common point can paſs, except the differential of its ordinate (dv) equals the differential (dy) of the ordinate y.

Again, ſuppoſe $y = u$, $\frac{dy}{dx}$ or $D \cdot y = \frac{du}{dx}$ or $D \cdot u$, $\frac{d^2 y}{dx^2}$ or $D^2 \cdot y = \frac{d^2 u}{dx^2}$ or $D^2 \cdot u$, then between theſe two curves no other curve (whoſe equation is $v = \downarrow x$) drawn through the common point where the ordinates are equal, can paſs, except $\frac{dv}{dx} = \frac{dy}{dx}$, and $\frac{d^2 v}{dx^2} = \frac{d^2 y}{dx^2}$.

For if it be poſſible, then $y' - v'$, or $(y + \Delta y) - (v + \Delta v)$ or, (ſince $y = v$ by hypotheſis), $\Delta y - \Delta v$ muſt be $< \Delta y - \Delta u$, however ſmall the interval (Δx) between the ordinates is; that is, putting for Δy, Δu, Δv, the ſeries they are equal to, to wit,

D. y

$$D \cdot y \cdot \Delta x + \overset{D^2}{c} \cdot y \cdot (\Delta x)^2 + \overset{D^3}{c} \cdot y \cdot (\Delta x)^3 + \&c.$$
$$D \cdot u \cdot \Delta x + \overset{D^2}{c} \cdot u \cdot (\Delta x)^2 + \overset{D^3}{c} \cdot u \cdot (\Delta x)^3 + \&c.$$
$$D \cdot v \cdot \Delta x + \overset{D^2}{c} \cdot v \cdot (\Delta x)^2 + \overset{D^3}{c} \cdot v \cdot (\Delta x)^3 + \&c.$$

it follows that $(D \cdot y - D \cdot v) \Delta x + (\overset{D^2}{c} \cdot y - \overset{D^2}{c} \cdot v) \cdot (\Delta x)^2$ &c. must always be less than $(\overset{D^3}{c} \cdot y - \overset{D^3}{c} \cdot u) \cdot (\Delta x)^3 + (\overset{D^4}{c} \cdot y - \overset{D^4}{c} \cdot u) \cdot (\Delta x)^4 + \&c.$ (for the two first terms in the difference $\Delta y - \Delta u$, to wit, $(D \cdot y - D \cdot u)$, $(\overset{D^2}{c} \cdot y - \overset{D^2}{c} \cdot u)$, by hypothesis $= 0$); but this is evidently impossible, except both, $D \cdot y - D \cdot v$, and $D^2 \cdot y - D \cdot v$, $= 0$; for, Δx can be taken of such a magnitude that $(D \cdot y - D \cdot v)$ shall be greater than $(\overset{D^2}{c} \cdot y - \overset{D^2}{c} \cdot v) \Delta x - (\overset{D^3}{c} \cdot y - \overset{D^3}{c} \cdot u) \cdot (\Delta x)^2 - \&c.$ or (in case that $D \cdot y = D \cdot v$) that, $(\overset{D^2}{c} \cdot y - \overset{D^2}{c} \cdot v)$ shall be greater than $(\overset{D^3}{c} \cdot u - \overset{D^3}{c} \cdot v) \Delta x + (\overset{D^4}{c} \cdot u - \overset{D^4}{c} \cdot v) \cdot (\Delta x)^2 + \&c.$ and generally, if two curves whose equations are $y = \varphi x$, $u = fx$ have these conditions, that at the same point of the abscissa, $y = u$, and moreover, $D \cdot y = D \cdot u$, $D^2 \cdot y = D^2 \cdot u$, $D^3 \cdot y = D^3 \cdot u$, &c. $D^{n-1} \cdot y = D^{n-1} \cdot u$, then between these two curves no other curve whose equation is $v = \downarrow x)$, drawn through the common point, can pass, except $D \cdot v = D \cdot y$, $D^2 \cdot v = D^2 \cdot y$, $D^3 \cdot v = D^3 \cdot y$, &c. and $D^{n-1} \cdot v = D^{n-1} \cdot y$; for, if such a curve can pass between the courses of the two other curves, then $\Delta y - \Delta v$ must be less than $\Delta y - \Delta u$, or less than $(\overset{D^n}{c} \cdot y - \overset{D^n}{c} \cdot u) \cdot (\Delta x)^n + (\overset{D^{n+1}}{c} \cdot y - \overset{D^{n+1}}{c} \cdot u) \cdot (\Delta x)^{n+1} + \&c.$ however small Δx is; but this is impossible, since the terms of the series representing $\Delta y - \Delta v$ must involve powers of Δx less than $(\Delta x)^n$, except $D \cdot v = D \cdot y$, $D^2 \cdot v = D^2 \cdot y$, $D^3 \cdot v = D^3 \cdot y$, &c. and $D^{n-1} \cdot v = D^{n-1} \cdot y$; and if these differentials are not equal, then dividing by a certain power of Δx, $\Delta y - \Delta v$ cannot always be less than $\Delta y - \Delta u$, if in a series, as $a + a' \cdot \Delta x + a'' \cdot (\Delta x)^2 + \&c.$ a can be made to exceed the sum of the succeeding terms; which evidently can be done by taking Δx of a proper smallness.

These are the principles on which the contact of curves is founded; the contact admits of different degrees; and arranging the contacts according to different orders, there are curves which admit with a given curve only of contacts of a certain order; for instance, a right line is capable only of a contact of the first order; a circle is only capable of a contact of the second order; a curve, whose equation is $y = a + b x + c x^2 + d x^3$, is not capable of a contact higher than that of the third order; a curve, whose equation $y = a + b x + c x^2 + d x^3 + e x^4$, is not capable of a contact higher than that of the fourth order, and so on; so that admitting these different degrees or orders of contact, they require a certain number of constant quantities, which may be called elements of contact: a contact of the first order will require two constant quantities; a contact of the second, three constant quantities, &c.; and a contact of the mth order $(m + 1)$, constant quantities.

As an example, let $u = a + b t$, which is the equation to a straight line; then since it is to pass through a point of the curve, $u = y$ and $t = x$, and $y = a + b x$, $\therefore D \cdot y$ or $\frac{d y}{d x} = b$, and $a = y - x \cdot b = y - x \cdot D \cdot y$, consequently the equation to the straight line is $u = y - x \cdot D \cdot y + D \cdot y \cdot t$, the abscissa x being considered constant.

The line determined by this equation is commonly called a tangent; and, agreeably to the theory of contacts laid down, its geometrical property consists in this, that no other straight line can pass between it and the curve whose equation is $y = \varphi x$: for, if possible, suppose a straight line whose equation is $v = \alpha + \beta t$, to pass between the curve and line, then since $v = y$, $t = x$, $y = \alpha + \beta x$, $\therefore \frac{d y}{d x}$ or $D \cdot y = \beta$, and $\alpha = y - \beta x = y - x \cdot D \cdot y$, and the equation to the straight line is $v = y - x \cdot D \cdot y + D \cdot y \cdot t$, which is the same equation as was deduced for the former straight line, consequently this latter straight line coincides or becomes identical with the former.

In the equation $u = a + b t$, A B (*Plate* VII. *Analysis*, *fig.* 6.) $= a$, A M $= t$, and b = tangent of angle $\angle$ P T M (radius 1) but $b = \frac{d y}{d x}$, and consequently T M $= \frac{y}{b} = \frac{y \, d x}{d y}$, and this is the value of the line T M called the subtangent; hence, in a given equation to a curve, find the value of $\frac{y \, d x}{d y}$, and make T M $= \frac{y \, d x}{d y}$, join T P, and the line T P is a tangent to the curve, or has the geometrical property before specified.

Example.—Let $y = \varphi x = (2 r x - x^2)^{\frac{1}{2}}$, then $\frac{d y}{d x} = \frac{r - x}{(2 r x - x^2)^{\frac{1}{2}}}$, consequently the subtangent $\frac{y \, d x}{d y} = y \cdot \frac{(2 r x - x^2)^{\frac{1}{2}}}{r - x} = \frac{y^2}{r - x}$.

Again, let the equation be $x^3 - 3 a x y + y^3 = 0$, then $3 x^2 d x - 3 a x d y - 3 a y d x + 3 y^2 d y = 0$, and consequently, $\frac{d x}{d y} = \frac{3 a x - 3 y^2}{3 x^2 - 3 a y} = \frac{a x - y^2}{x^2 - a y}$, and the subtangent $\left(\frac{y \, d x}{d y}\right) = \frac{a x y - y^3}{x^2 - a y}$.

Let a line K P be drawn perpendicular to the tangent T P, then it equals $y \sqrt{(1 + (D \cdot y)^2)}$, or $y \sqrt{\left(1 + \left(\frac{d y}{d x}\right)^2\right)}$, for T M : P M :: P M : M K; $y \cdot \frac{d x}{d y} : y ::$ $y : y \cdot \frac{d y}{d x} =$ M K; P K$^2 = y^2 \left(\frac{d y}{d x}\right)^2 + y^2$; P K $= y \sqrt{1 + (D y)^2}$, because P K is secant to the angle M P K, whose tangent is $\frac{d y}{d x}$ and rad. 1; and consequently, K M $= y \frac{d y}{d x}$, or $y \cdot D \cdot y$; the line K P is called the normal, the line K M the subnormal.

Draw the line $m p$ parallel to M P, then $m p =$ M P $+ p t = y +$ P $t \times$ tan. $\angle$ P T M $= y + b \cdot \Delta x = y + \frac{d y}{d x} \cdot \Delta x$, or $y + D \cdot y \cdot \Delta x$, but $m r = y + D \cdot y \cdot \Delta x + \overset{D^2}{c} \cdot y \cdot (\Delta x)^2 + \&c.$ consequently, the difference or $p r = -\left(\overset{D^2}{c} \cdot y \cdot (\Delta x)^2 + \overset{D^3}{c} \cdot y \cdot (\Delta x)^3 + \&c.\right)$, take Δx such, that the first term shall be greater than the sum of all the succeeding terms, then $p r$ will be negative or positive, as $\overset{D^2}{c} \cdot y$ is positive or negative, for $(\Delta x)^2$ is always

positive, consequently if $D^2 . y$ be negative, the point r is between m and p, or the curve is said to be concave to the axis; if $\overset{D_2}{c} . y$ be positive, the point p is between m and r, and the curve is said to be convex to the axis.

Ex.—Let $y = a + bx + cx^2$, then $\frac{dy}{dx} = b + 2cx$, $\frac{d^2y}{dx^2}$, or $D^2 . y = 2c$, consequently the curve is convex to the axis.

Again, let $y = (ax)^{\frac{1}{m}}$, then $\frac{dy}{dx} = \frac{a^{\frac{1}{m}}}{m} x^{\frac{1-m}{m}}$, and $\frac{d^2y}{dx^2}$ or $D^2 . y = a^{\frac{1}{m}} \frac{1-m}{m^2} x^{\frac{1-2m}{m}}$, consequently if m is > 1, $D^2 . y$ is negative, and the curve is concave to the axis.

If $\frac{d^2y}{dx^2}$ or $D^2 . y = 0$, the curve is said to have a point of inflexion: for, in this case the difference between mp and mr or $pr = \overset{D_3}{c} . y . (\Delta x)^3 + \overset{D_4}{c} . y . (\Delta x)^4 +$ &c. now take Δx such, that the term $D^3 . y . (\Delta x)^3$, exceeds the sum of the remaining, then, since the first term $D^3 . y . (\Delta x)^3$ changes its sign, when Δx does, the difference pr will likewise change its sign when Δx does, or, if on one side of the ordinate (y) the curve is convex, on the other it will be concave.

If $D^2 . y$, $D^3 . y = 0$, then the curve will not have a point of inflexion, for the difference between mp and mr will be $-(\overset{D_4}{c} . y . (\Delta x)^4 + \overset{D_5}{c} . y . (\Delta x)^5 +$ &c.), and consequently its sign will depend solely on the sign of $D^4 . y$, and not on the sign of Δx, for $(\Delta x)^4$ is positive whether Δx is positive or negative; and generally if $D^2 . y = 0$, $D^3 . y = 0$, $D^4 y = 0$, &c. and $D^m . y = 0$, (m even) then the curve has a point of inflexion.

It has appeared, that generally the difference

$$pr = -(\overset{D_2}{c} . y . (\Delta x)^2 + \overset{D_3}{c} . y . (\Delta x)^3 + \text{&c.})$$
$$= -(\Delta x)^2 (\overset{D_2}{c} . y + \overset{D_3}{c} . y . \Delta x + \overset{D_4}{c} . y . (\Delta x)^2 + \text{&c.})$$

; now since Δx may be taken so small, that a term, as $\overset{D_3}{c} . y . \Delta x$, is greater than the sum of all the succeeding terms, it is plain that the difference between pr and $(\Delta x)^2 . \overset{D_2}{c} . y$ or $\frac{d^2y}{1 . 2 . dx^2} . (\Delta x)^2$ may be made less than any assignable quantity: this is all that is to be understood in the present method, concerning any equality between a certain state of pr and $D^2 . y . (\Delta x)^2$; in the method of fluxions, or of prime and ultimate ratios, the ultimate ratio of pr, or the sagitta of the arc or evanescent subtense, is made $= \frac{d^2y}{1 . 2 . dx^2} . dx^2$; not indeed absolutely and metaphysically equal, but equal according to the definition of equality necessary to be laid down in that method.

A straight line admits, it has appeared, only of a contact of the first order, its equation $u - a - bt = 0$, containing only two constant quantities (a, b) or elements of contact: a curve whose equation is $u = a + bt + ct^2$, in which there are three elements of contact, or constant quantities, admits of a contact of the second order; or its geometrical property is such, that if $t = x$, $u = y$, $du = dy$, $d^2u = d^2y$, no other curve of the same kind can pass between its course, and that of the curve whose equation is $y = fx$.

In like manner, the equation to the circle containing only three constant quantities, the circle admits of no contact higher than that of the second order. Although the principles on which its contact with curves depends are the principles of the general theory, and properly form no exception, yet the contact of circles may merit a particular examination, from the rank that the theory of osculation or of circles of curvature holds in the history of science: Newton was led by it to his theory of central forces.

Let the circle and curve have a common point P, then since $PL^2 + LO^2 = OP^2$, or $(PM - LM)^2 + (AN - AM)^2 = OP^2$ putting $PM = u$, LM or $ON = b$, $AN = a$, $AM = t$, $(u - b)^2 + (a - t)^2 = r^2$, and consequently $u = b + \sqrt{(r^2 - (a - t)^2)}$: at the common point $u = y$, $t = x$, $\therefore y = b + \sqrt{(r^2 - (a - x)^2)}$ $\therefore \frac{dy}{dx}$ or $D . y = (a - x)(r^2 - (a - x)^2)^{-\frac{1}{2}}$; and since

$LO : OP :: MK : PK$

$$a - x : r :: y\frac{dy}{dx} : y\sqrt{1 + Dy^2} :: D . y : \sqrt{1 + Dy^2},$$

$$a - x = \frac{r . D . y}{\sqrt{1 + Dy^2}}$$

but $PL : PO :: PM : PK$

$$y - b : r :: y : y\sqrt{1 + (Dy)^2}$$

$$y - b = \frac{r}{\sqrt{1 + (Dy)^2}}$$

hence, $a = x + \frac{r . D . y}{\sqrt{(1 + (D . y)^2)}}$ and $b = y - \frac{r}{\sqrt{(1 + (D . y)^2)}}$, and consequently, in terms of y or x, the co-ordinates a and b, by which the centre is determined, are expressed.

The elements a and b, on which the degree of contact depends, have been determined on these two conditions, *viz.* that $u = y$, and that $\frac{du}{dx} = \frac{dy}{dx}$, and agreeably to the theory laid down, the circle whose radius is r, and the position of whose centre is determined by the values of the co-ordinates deduced as above, is such, that between it and the curve no other circle of the same radius can be drawn, having its centre placed differently.

For if possible, let the equation to such a circle be $(v - \beta)^2 + (\alpha - t)^2 = r^2$ or $v = \beta + \sqrt{(r^2 - (\alpha - t)^2)}$, at the common point $v = y$, hence, α and β are to be determined from the equations $y = \beta + \sqrt{(r^2 - (\alpha - x)^2)}$ and $D . y = (\alpha - x)(r^2 - (\alpha - x)^2)^{-\frac{1}{2}}$, which equations are exactly similar to those from which a and b were determined: consequently α and β deduced, will be expressed by the same quantities as a and b are, or the new circle will become identical, or coincide, with the former.

Since the conclusions deduced as above do not depend on the magnitude of r, suppose it indeterminate in the expressions for a and b; then since from one expression r equals $\frac{(a - x)\sqrt{(1 + (D . y)^2)}}{D . y}$ and from the other $(y - b)\sqrt{(1 + (D . y)^2)}$, equate the two values, and there results $a - x = (y - b) . D . y$, or $b = y + \frac{x - a}{D . y}$ an equation to a right line in which are placed the centres of all the circles

circles that touch the curve, that is, that have with it a contact of the firſt order.

The value of the ſubnormal has been found $= y \cdot D \cdot y$ and the tangent of the angle which the normal makes with the axis is $\frac{1}{D \cdot y}$, ſuppoſe now P K to be the normal, then the equation to it, conſidered as a right line is (ſince P M = P L + O N = M N × tangent ∠ P K M + O N) $y = \frac{a - x}{D \cdot y} + b$, conſequently, $b = y + \frac{x - a}{D \cdot y}$, the ſame equation as has been juſt deduced for the right line in which the centres of all the circles that touch the curve are placed: hence, this right line coincides with the normal, and is conſequently perpendicular to the tangent of the curve.

Suppoſe it now were required, from all the circles which touch the curve, that is, which ſatisfy theſe conditions, *viz.* $y = u$, $\frac{d y}{d x} = \frac{d u}{d x}$, to ſelect that which has with the given curve a contact, ſuch, that between it and the curve no other circle can be drawn, or which, analytically ſpeaking, ſatisfies the condition $\frac{d^2 y}{d x^2} = \frac{d^2 u}{d x^2}$: now, by what has preceded,

$$a = x + \frac{r \cdot D \cdot y}{\sqrt{(1 + (D^2 \cdot y)^2)}}, \text{ and } b = y - \frac{r}{\sqrt{(1 + (D \cdot y)^2)}};$$

again, $\frac{d^2 y}{d x^2}$ or $D^2 \cdot y = \frac{1}{d x} \cdot d \left(\frac{d y}{d x}\right) = \frac{1}{d x} \cdot d$

$$\left(\frac{a - x}{\sqrt{(r^2 - (a - x)^2)}}\right) = - \frac{r^2}{(r^2 - (a - x)^2)^{\frac{3}{2}}} = -$$

$$\frac{r^2}{\left(r^2 - \frac{r^2 \cdot (D \cdot y)^2}{1 + (D \cdot y)^2}\right)^{\frac{3}{2}}} = - \frac{(1 + (D \cdot y)^2)^{\frac{3}{2}}}{r}$$

and conſequently, $r = \frac{(1 + (D \cdot y)^2)^{\frac{3}{2}}}{- D^2 \cdot y}$ or $= \frac{(d x^2 + d y^2)^{\frac{3}{2}}}{- d x \cdot d^2 y}$

and $a = x - \frac{D \cdot y \cdot (1 + (D \cdot y)^2)}{D^2 \cdot y}$ or $= - \frac{d y \cdot (d x^2 + d y^2)}{d x \cdot d^2 y}$,

and $b = y + \frac{1 + (D \cdot y)^2}{D^2 \cdot y}$ or $= y + \frac{d x^2 + d y^2}{d^2 y}$.

By theſe equations are determined the co-ordinates of the centre of a circle, and the radius of that circle which is ſuch, that between it and the curve no other circle can paſs; for, if it be poſſible for another circle to paſs between the curve and the former circle, let its equation be $v = \beta + \sqrt{(\varrho^2 - (\alpha - t)^2)}$, then the three elements of contact, to wit, α, β, ϱ, are to be determined from the three equations

$$y = \beta + \sqrt{(\varrho^2 - (\alpha - x)^2)}, \; D \cdot y = (\alpha - x)$$

$$(\varrho^2 - (\alpha - x)^2)^{-\frac{1}{2}} \text{ and } D^2 \cdot y = - \frac{\varrho^2}{(\varrho^2 - (\alpha - x)^2)},$$

which equations are exactly ſimilar to the equations by which the elements a, b, r were determined; conſequently, after elimination, α, β, ϱ will be exhibited by the ſame forms as a, b, r have been exhibited; or in other words, the new circle will become identical with the former.

Let it now be required to inveſtigate an expreſſion from which the areas of curves may be found. Suppoſe y the ordinate of the curve, then at an interval Δx the ordinate is $y + \Delta y = y + D \cdot y \cdot \Delta x + \overset{c}{D^2} \cdot y \cdot (\Delta x)^2 +$ &c. and the incremental area between the ordinates y and $y + \Delta y$ is $> y \cdot \Delta x$, and $< (y + \Delta y) \cdot \Delta x$, the ordinates increaſing, or $< y \cdot \Delta x$, and $> (y + \Delta y) \cdot \Delta x$; the ordinates diminiſhing; let now the area be repreſented by $f x = u$, a function of the abſciſſa, then $f \cdot (x + \Delta x) - f x$, or Δu is between the limits $(y + \Delta y) \cdot \Delta x$, and $y \cdot \Delta x$; hence $\Delta u - y \cdot \Delta x$ muſt always be leſs than $(y + \Delta y) \cdot \Delta x - y \cdot \Delta x$, however ſmall Δx is, or putting for Δu, Δy their expanded ſeries, $(D \cdot u - y) \cdot \Delta x + \overset{c}{D^2} \cdot u \, (\Delta x)^2 +$ &c. is $< \Delta y \cdot \Delta x$, or $< D \cdot y \cdot (\Delta x)^2 + \overset{c}{D^2} \cdot y \cdot (\Delta x)^3 +$ &c. and conſequently $(D \cdot u - y) + \overset{c}{D^2} \cdot u \cdot \Delta x +$ &c. muſt be $< D \cdot y \cdot \Delta x + \overset{c}{D^2} \cdot y \cdot (\Delta x)^2 +$ &c. however ſmall Δx is, which is evidently impoſſible, except $D \cdot u - y = 0$; for the difference of the two expreſſions being $(D \cdot u - y) + (\overset{c}{D} \cdot u - D \cdot y) \cdot \Delta x + (\overset{c}{D^2} \cdot u - \overset{c}{D^2} \cdot y) \cdot (\Delta x)^2 +$ &c. it is evident that Δx may be taken ſuch, that $(D \cdot u - y)$ ſhall be greater than the ſum of all the ſucceeding terms; hence $D \cdot u - y$ or $\frac{d u}{d x} = y$ or $d u = y \, d x$; and conſequently $d^{-1} (d u)$ or $u = d^{-1} (y \, d x)$.

Hence to find the area is merely an analytical queſtion, the ordinate being given a function of the abſciſſa; what is to be done, is, the determination of the integral of a given differential expreſſion.

If $y = a + b x^n + c x^r$, $d u = a \, d x + b x^n \, d x + c x^r \, d x$, and $u = a x + \frac{b x^{n+1}}{n + 1} + \frac{c x^{r+1}}{r + 1} + \alpha$, α being an arbitrary quantity, which in ſpecific caſes may be determined.

The differential expreſſion from which the ſolidity of a body is to be calculated, may be thus obtained.

Let $f x$ be a ſection of the ſolid, made perpendicular to the axis; let s, a function of the abſciſſa, repreſent the ſolidity, then Δs is contained between the limits $f (x + \Delta x) \Delta x$, and $f x \cdot \Delta x$, conſequently $\Delta s - f x \cdot \Delta x$ is $< (f (x + \Delta x) - f x) \cdot \Delta x$, or $(D \cdot s - f x) \cdot \Delta x + \overset{c}{D^2} s \cdot (\Delta x)^2 +$ &c. is $< D f x \cdot (\Delta x)^2 + \overset{c}{D^2} f x \cdot (\Delta x)^3 +$ &c. and conſequently, $(D \cdot s - f x) + \overset{c}{D^2} s \cdot \Delta x +$ &c. $< D f x \cdot \Delta x + \overset{c}{D^2} f x \cdot (\Delta x)^2 +$ &c. however ſmall Δx be taken, which is impoſſible, except $D \cdot s - f x = 0$, ſince Δx may be taken ſo ſmall, that $(D f x - \overset{c}{D^2} \cdot s) \Delta x + a \cdot (\Delta x)^2 + a' \cdot (\Delta x)^3 +$ &c. (putting a, a' &c. for the co-efficients of the terms affected with (Δx), $(\Delta x)^2$, &c.) is leſs than $D \cdot s - f x$, and à fortiori leſs for all ſmaller values of Δx; hence $D \cdot s = f x$, or $\frac{d s}{d x} = f x$, or $d s = f x \cdot d x$: if the ſolid can be conceived to be generated by the revolution of a figure round its axis, the ſection, the area of which is repreſented by $f x$, is a circle, conſequently if y be its radius, $p = 3{:}14159 +$ &c. $f x = p y^2$, and thence $d s = p y^2 \, d x$, and $s = d^{-1} (p y^2 \, d x)$.

The differential expreſſion next to be deduced is that on which the rectification of curves depends, or from which their lengths may be calculated. The expreſſion may eaſily be deduced if the aſſumption of Archimedes be admitted, which is nearly as follows, that of lines having the ſame terminations, that which is a right line is the leaſt, and if two figures have the ſame ſtraight line for their baſe, that which is contained within the other, if it is always concave towards the baſe, is the leaſt; from which it immediately follows that the arc M, M′, M″, (*fig.* 7.) is greater than the chord drawn from m to M″, and leſs than M q + q M″; the limits within

within which the arc is contained being determined, the differential expreſſion by which its length is to be calculated may be obtained thus:

Draw M Z perpendicular to Z P; let M′ r, M t, t Q, be tangents, then the arc M M′ > chord M M′ is > M′ r (ſuppoſing M′ r produced to cut the axis to the left of M P; again, arc M M′ Q is < M t + t Q, but arc M′ Q is > t Q (for ſame reaſon as arc M M′ is > M′ r); conſequently arc M M is < M t and > M′ r; now if P P′ be Δx, M t = $\Delta x \sqrt{(1 + (D \cdot y)^2)}$ and calling P′ M′, y', M′ r = $\Delta x \sqrt{(1 + (D \cdot y)^2)}$, therefore arc M M′, or ſuppoſing z a function of x to repreſent the arc, Δz is < $\Delta x \sqrt{(1 + (D \cdot y)^2)}$, > $\Delta x \sqrt{(1 + (D \cdot y)^2)}$, and conſequently

$\Delta x \sqrt{(1 + (D \cdot y)^2)} - \Delta z$ ought to be

$< \Delta x \sqrt{(1 + (D \cdot y)^2)} - \Delta x \sqrt{(1 + (D \cdot y)^2)}$

but $\Delta z = D \cdot z \cdot \Delta x + {}^{D_2}_{c} z \cdot (\Delta x)^2 +$ &c.

$y' = y + D \cdot y \cdot \Delta x + {}^{D_2}_{c} y \cdot (\Delta x)^2 +$ &c. conſequently $D \cdot y' = D \cdot y + {}^{D_2}_{c} \cdot y \cdot \Delta x + \frac{D^3 \cdot y}{1 \cdot 2} \cdot (\Delta x)^2$ + &c. and $\sqrt{(1 + (D \cdot y)^2)} = \sqrt{(1 + (D \cdot y)^2)} + 2 \cdot D \cdot y \, (D^2 \cdot y \cdot \Delta x + \frac{D^3 \cdot y}{1 \cdot 2} \cdot (\Delta x)^2 +$ &c.) $= \sqrt{(1 + (D \cdot y)^2)} + a \cdot \Delta x + (\Delta x)^2 +$ &c. putting a, a' &c. for the co-efficients of Δx. $(\Delta x)^2$, &c. hence

$\left(\sqrt{(1 + (D \cdot y)^2)} - D \cdot z\right) \Delta x - {}^{D_2}_{c} \cdot z \cdot (\Delta x)^2 - {}^{D_3}_{c} \cdot z \cdot (\Delta x)^3 -$ &c. muſt be $< a \cdot (\Delta x)^2 + a' \cdot (\Delta x)^3 +$ &c. or

$\left(\sqrt{(1 + (D \cdot y)^2)} - D \cdot z\right) - {}^{D_2}_{c} \cdot z \cdot \Delta x -$ &c. $< a \cdot \Delta x + a' \cdot (\Delta x)^2 +$ &c. however ſmall Δx is, but, as it has been ſhewn in preceding caſes, this is impoſſible, except $\sqrt{(1 + (D \cdot y)^2)} - D \cdot z = 0$; conſequently, ſince the difference between the arc and one of its limits muſt be leſs than the difference between the limits, $\sqrt{(1 + (D \cdot y)^2)} - D \cdot z$ muſt be = 0, or $D \cdot z = \sqrt{(1 + (D \cdot y)^2)}$,

$$\text{or } \frac{d z}{d x} = \sqrt{\left(1 + \left(\frac{d y}{d x}\right)^2\right)}$$

$$\text{or } d z = \sqrt{(d x^2 + d y^2)}.$$

Ex. 1.—Let $a^{\frac{1}{2}} y = x^{\frac{3}{2}}$, then $d y = \frac{3}{2\sqrt{a}} x^{\frac{1}{2}} \cdot d x$, and $d y^2 = \frac{9}{4a} x \, d x^2$, and $d x^2 + d y^2 = \frac{d x^2}{4a} (4a + 9x)$, conſequently, $d z = \sqrt{(d x^2 + d y^2)} = \frac{d x}{2\sqrt{a}} \sqrt{(4a + 9x)}$, and integrating $z = \frac{(4a + 9x)^{\frac{3}{2}}}{27\sqrt{a}} + \alpha$, α being an arbitrary quantity called the correction; if $z = A$, when $x = r$, then $A = \frac{(4a + 9r)^{\frac{3}{2}}}{27\sqrt{a}} + \alpha$, conſequently, $= A - \frac{(4a + 9r)^{\frac{3}{2}}}{27\sqrt{a}}$.

Ex. 2.—Let $y = \sqrt{(1 - x^2)}$, $\therefore d y = \frac{-x \, d x}{-\sqrt{1 - x^2}}$, $d y^2 = \frac{x^2 \cdot d x^2}{1 - x^2}$, and $d x^2 + d y^2 = d x^2 + \frac{x^2 \cdot d x^2}{1 - x^2} = \frac{d x^2}{1 - x}$, conſequently, $d z \frac{d x}{\sqrt{(1 - x)}}$ = (by expanſion), $d x \, (1^{-\frac{1}{2}} - D \, 1^{-\frac{1}{2}} \cdot x^2 + {}^{D_2}_{c} \, 1^{-\frac{1}{2}} \cdot x^4 -$ &c.) (in which $D \, 1^{-\frac{1}{2}}$, ${}^{D_2}_{c} \, 1^{-\frac{1}{2}}$, &c. are uſed as ſymbols, ſignifying reſpectively $-\frac{1}{2}$, $\frac{1}{8}$, &c) and $z = x - \frac{D \, 1^{-\frac{1}{2}} \cdot x^3}{3} + {}^{D_2}_{c} \, 1^{-\frac{1}{2}} \frac{x^5}{5}$ + &c. + α, or $= x + \frac{x^3}{2 \cdot 3} + \frac{3}{5 \cdot 8} x^5$ + &c. + α, (α an arbitrary conſtant quantity).

Let it now be required to inveſtigate the differential expreſſion from which the ſurface of a ſolid may be deduced.

It has been ſhewn that the arc M M′ is < M t > M′ r: now if the figure be conceived to revolve round T P, then P T, P M′ deſcribe circles, M t, M′ r conical ſurfaces, and M M′ a conoidal ſurface, which will be contained between the conical ſurfaces generated by M t, M′ r; now the conical ſurface belonging to M t = $\frac{1}{2}$ (2 p. P t + 2 p. P M) M t (p = 3.14159 + &c.) = p. M t (P′ t + P M), and the conical ſurface belonging to M′ r = p. M′ r (M′ P′ + P r), now P t = y + D . y . Δx, P r = y' − D . y' . Δx, M t = $\Delta x \sqrt{(1 + (D \cdot y)^2)}$, M′ r = $\Delta x \sqrt{(1 + (D \cdot y')^2)}$, let the expreſſion $\sqrt{(1 + (D \cdot y)^2)} = \downarrow x$, then ſince y' is what y becomes, putting for x, $x + \Delta x \sqrt{(1 + (D \cdot y')^2)} = \downarrow (x + \Delta x)$; hence the ſurface is < $p \cdot \Delta x \cdot \downarrow x \, (2y + D y \cdot \Delta x)$, > $p \cdot \Delta x \cdot \downarrow (x + \Delta x) \cdot (2y' - D y' \cdot \Delta x)$, let the function of x repreſenting the ſurface be V, then the portion belonging to M M′ = Δ V = D V . Δx + ${}^{D_2}_{c}$ V . $(\Delta x)^2$ + ${}^{D^3}_{c}$ V . $(\Delta x)^3$ + &c. hence this latter quantity being conſtantly contained between the two limits above-mentioned, the difference between it and one of the limits muſt be leſs than the difference between the limits, or $p \cdot \downarrow x \{(2y + D \cdot y \cdot \Delta x) - D \cdot V) \Delta x - {}^{D_2}_{c} V \cdot (\Delta x)^2 -$ &c. $< p \cdot \Delta x \{\downarrow x (2y + D \cdot y \cdot \Delta x) - \downarrow (x + \Delta x) \cdot (2y' - D y' \cdot \Delta x)\}$ or $(p \cdot \downarrow x \cdot 2y - D \cdot V) \cdot \Delta x + a \cdot (\Delta x)^2 + b \cdot (\Delta x)^3 +$ &c. $< a' \cdot (\Delta x)^2 + b' \cdot (\Delta x)^3 +$ &c. (a, a', b, b', &c. repreſenting co-efficients affected with powers of Δx) for ſince $\downarrow (x + \Delta x) = \downarrow x + D \downarrow x \cdot \Delta x + {}^{D_2}_{c} \downarrow x \cdot (\Delta x)^2 +$ &c. and $2y' = 2y + 2D \cdot y \cdot \Delta x +$ &c. the firſt term in the expanded ſeries, for $\downarrow (x + \Delta x) (2y' - D y' \cdot \Delta x) = 2y \cdot \downarrow x =$ firſt term in the expanded ſeries for $\downarrow x (2y + D \cdot y \cdot \Delta x)$, and hence it follows, that the firſt term in $p \cdot \Delta x \{\downarrow x \cdot (2y + D \cdot y \cdot \Delta x) - \downarrow (x \Delta + x) (2y' - D \cdot y' \cdot \Delta x)\}$ contains $(\Delta x)^2$; conſequently, ſince the difference between the limit and D . V, or $(p \cdot \downarrow x \cdot 2y - D \cdot V) \cdot \Delta x + a \cdot (\Delta x)^2 +$ &c. muſt be leſs than the difference between the limits, of the form $a' (\Delta x)^2 + b' (\Delta x)^3 +$ &c. however ſmall Δx is, this cannot happen except $p \cdot \downarrow x \cdot 2y - D \cdot V = 0$, or $p \cdot \downarrow x \cdot 2y = \frac{d V}{d x}$, or $p \cdot \sqrt{(1 + (D \cdot y)^2)} \cdot 2y = \frac{d V}{d x}$, or $p \cdot \sqrt{(d x^2 + d y^2)} \cdot 2y = d V$, or calling $\sqrt{(d x^2 + d y^2)}$, $d z$, $d V = 2 p y \, d z$, the differential expreſſion from which the ſurface is to be found.

If $y^2 = a x$, $d x^2 = \frac{4 y^2 \cdot d y^2}{a^2}$, and $\sqrt{(d x^2 + d y^2)} =$

$d y$

$\frac{dy\sqrt{(a^2+4y^2)}}{a}$, and $dV = \frac{2p}{a} y\,dy\sqrt{(a^2+4y^2)}$, consequently $V = \frac{2p}{a} \cdot \frac{(a^2+4y^2)^{\frac{3}{2}}}{12} = \frac{p}{6a}(a^2+4y^2)^{\frac{3}{2}} + \alpha$, ($\alpha$ being a conſtant arbitrary quantity).

The manner in which Mr. Woodhouſe applies theſe principles to explain ſome propoſitions in the doctrine of motion, is particularly deſerving of attention, as it is the converſe method to that moſt uſually followed by fluxionary writers.

The laws of motion are here beautifully illuſtrated from principles derived by fair induction from the proceſſes of common algebra, whereas, thoſe writers uſually purſue a method entirely the reverſe, and inſtitute algebraical proceſſes from the theory of motion.

To determine the circumſtances under which a function φx admits of a maximum or minimum,

Let x be increaſed by Δx; then $\varphi(x+\Delta x) = \varphi x + D\varphi x \cdot \Delta x + \overset{D^2}{c}\varphi x \cdot (\Delta x)^2 +$ &c. or $y + D \cdot y \cdot \Delta x + \overset{D^2}{c} \cdot y \cdot (\Delta x)^2 +$ &c.; now in caſe of a maximum y is $> y + \Delta y$, or $> y + D \cdot y \cdot \Delta x + \overset{D^2}{c} \cdot y \cdot (\Delta x)^2 +$ &c.; and in caſe of a minimum $< y + D \cdot y \cdot \Delta x + D^2 \cdot y \cdot (\Delta x)^2 +$ &c., or $D \cdot y \cdot \Delta x + \overset{D^2}{c} \cdot y \cdot (\Delta x) +$ &c. is < 0 in caſe of a maximum, and > 0 in caſe of a minimum, whatever Δx is; now Δx may be taken ſuch, that the firſt term, to wit, $D \cdot y \cdot \Delta x$ is greater than the reſt of all the ſucceeding terms; conſequently $D \cdot y \cdot \Delta x + \overset{D^2}{c} \cdot y \cdot (\Delta x)^2 +$ &c. is > 0, or < 0, accordingly as $D \cdot y \cdot \Delta x$ is poſitive or negative: but $D \cdot y \cdot \Delta x$ changes its ſigns with Δx, conſequently, taking Δx, $+\Delta x$, and $-\Delta x$, $D \cdot y \cdot \Delta x + \overset{D^2}{c} \cdot y \cdot (\Delta x)^2 +$ &c. cannot be always < 0, in caſe of the maximum, nor > 0 in caſe of the minimum, except $D \cdot y = 0$; hence, when y or φx is at a ſtate of maximum or minimum, $D \cdot y$ or $\frac{dy}{dx} = 0$.

Again, ſince the co-efficient $D \cdot y$ or $\frac{dy}{dx} = 0$, then $\overset{D^2}{c} \cdot y \cdot (\Delta x)^2 + \overset{D^3}{c} \cdot y \cdot (\Delta x)^3 +$ &c. muſt be < 0 in caſe of a maximum, and > 0 in caſe of a minimum: take Δx ſuch that the firſt term, namely, $\overset{D^2}{c} \cdot y \cdot (\Delta x)^2$, is greater than the ſum of all the ſucceeding terms; then ſince $(\Delta x)^2$ is poſitive, whether Δx be poſitive or negative, $\overset{D^2}{c} \cdot y \cdot (\Delta x)^2 + \overset{D^3}{c} \cdot y \cdot (\Delta x)^3 +$ &c. is < 0 or > 0, accordingly as $\overset{D^2}{c} \cdot y$ or $\frac{d^2y}{dx^2}$ is negative or poſitive; hence, for a maximum $\overset{D^2}{c} y$ is negative, for a minimum, poſitive.

Next, ſuppoſe the co-efficients $D \cdot y$, $D^2 \cdot y$, both to equal 0, then $\overset{D^3}{c} \cdot y \cdot (\Delta x)^3 + \overset{D^4}{c} \cdot y\,(\Delta x)^4 +$ &c. is < 0 for a maximum, and > 0 for a minimum; take Δx ſuch that the firſt term $D^3 y\,(\Delta x)^3$ is greater than the ſum of all the ſucceeding terms: then ſince $\overset{D^3}{c} \cdot y \cdot (\Delta y)^3$ changes its ſign as Δx does, $\overset{D^3}{c} \cdot y \cdot (\Delta x)^3 + \overset{D^4}{c} \cdot y\,(\Delta x)^4 +$ &c. cannot always < 0 for a maximum, nor > 0 for a minimum, except $\overset{D^3}{c} \cdot y = 0$, or $\frac{dy}{dx^3} = 0$.

And generally, if $D \cdot y$, $\overset{D^2}{c} \cdot y$, $\overset{D^3}{c} \cdot y$, &c. $D^m \cdot y$ (m even) $= 0$; then that the function $y\,(\varphi x)$ may admit a maximum or minimum, $D^{m+1} \cdot y$ muſt alſo be $= 0$; and for a maximum $D^{m+2} \cdot y$ muſt be negative, and for a minimum poſitive.

Such are the methods for determining the maxima and minima of quantities; the principles on which they are founded are ſufficiently evident, and merely analytical examples cannot illuſtrate them.

It was in attempting the ſolution of theſe problems *de maximis et minimis*, that the differential calculus is ſaid to have originated. Fermat is the firſt writer who has given a method purely analytical. His method conſiſts in making the quantity whoſe maximum or minimum is ſought equal to the expreſſion of the ſame quantity, in which the unknown quantity is augmented by an indeterminate quantity: in this equation he makes the radicals and fractions, if any diſappear, and having exterminated the common terms on each ſide of the equation, he divides the others by the indeterminate quantity by which they are multiplied; then he makes this quantity *zero*, and obtains an equation which ſerves to determine the unknown quantity. The following ſimple example will ſerve to illuſtrate the method of Fermat.

Let it be required to divide a right line into two parts, in ſuch a manner that the rectangle contained by the two parts may be a maximum.

Let a be the given line, x one part, and $a - x$ the other. The expreſſion $ax - x^2$ is then to be a maximum. Add the arbitrary quantity e to the unknown quantity x, and we obtain this new expreſſion,

$$a(x+e) - (x+e)^2.$$

Theſe expreſſions being ſuppoſed equal

$$ax - x^2 = a(x+e) - (x+e)^2,$$
$$\text{or } ax - x^2 = ax + ae - x^2 - 2ex - e^2;$$

ſubtract $a - x^2$ from each ſide, and divide by e

$$a - 2x - e = 0:$$

now ſuppoſe $e = 0$, then $a - 2x = 0$, and $x = \frac{a}{2}$.

This is the ſame reſult as obtained by the fluxional or differential method, and the baſis on which they are all founded is very ſimilar. The terms which are rejected as infinitely ſmall by ſome writers on the infiniteſimal calculus, are here ſuppreſſed, as vaniſhing or becoming zero in the method by Fermat. His method of drawing tangents depends on the ſame principle; in the equation between the abſciſſa and the ordinate, which Fermat calls the ſpecific property of the curve, he augments or diminiſhes the abſciſſa by an indeterminate quantity, and he regards the new ordinate as belonging at once to the curve and tangent, which produces an equation which he treats as in the above method *de maximis et minimis*.

Thus x being the abſciſſa and y the ordinate, if t is the ſubtangent at the point of the curve which anſwers to x and y, then by ſimilar triangles $\frac{y(t+e)}{t}$ for the ordinate to the tangent relative to the abſciſſa $x + e$; and this ordinate ſhould be equal to that of the curve for the ſame abſciſſa $x + e$: we ſhall therefore have the required equation, if in the equation for the curve we ſubſtitute $x + e$ in the place of x and $y + \frac{ye}{t}$ in the place of y. This equation will be diviſible by e; all its terms then are to be divided by e, and afterwards thoſe ſuppreſſed in which the indeterminate quantity e is found, becauſe this indeterminate quantity is ſuppoſed now to become zero. The remaining equation will give the value of t in the terms of x and y. Thus in the parabola for example,

whoſe equation $y^2 - ax = 0$, ſubſtituting $y + \frac{ye}{t}$ for y, and $x + e$ for x, the equation becomes

$$y^2 + \frac{2y^2e}{t} + \frac{y^2e^2}{t^2} - ax - ae = 0.$$

But $y^2 - ax = 0$; therefore rejecting theſe terms, and dividing others by e,

$$\frac{2y^2}{t} + \frac{y^2e}{t^2} - a = 0$$

rejecting the ſecond term, e being now ſuppoſed $= 0$,

$$t = \frac{2y^2}{a} = 2x.$$

We may here likewiſe trace the analogy between the method of Fermat and the differential calculus; for the indeterminate quantity e, by which x is augmented, anſwers to the differential dx; and $\frac{ye}{t}$, the correſponding augmentation of y, anſwers to its differential dy.

This idea of Fermat ſeems to have been original, but ſomewhat obſcure. It conſiſts in introducing into an equation an indeterminate quantity, which is afterwards ſuppoſed to become zero, by the conditions of the problem, but which is not made to vaniſh till the whole equation has been divided by it. This idea may be conſidered as the germ of the *new calculus*, by which ſuch rapid advances have been made in geometry and mechanics. But the obſcurity of its origin ſtill remains a blemiſh in the elementary principles, as delivered by moſt writers on this ſubject. They are all liable to the objection, urged by Berkly, of a *ſhifting of hypotheſis*; that is, equations are eſtabliſhed upon the ſuppoſition of a ſymbol having an actual exiſtence as a quantity, and conſequences are then eſtabliſhed which are preſumed to hold good, when the hypotheſis is entirely changed by making the ſymbol equal to zero.

The cotemporaries of Fermat did not enter into the ſpirit of this mode of calculation, they conſidered it as only a particular artifice, applicable to a few caſes, and ſubject to many difficulties. In the third volume of the letters of Deſcartes may be ſeen a long diſpute with Fermat upon this ſubject. Thus this invention, which appeared a ſhort time previous to the *geometrie de Deſcartes*, remained dormant and neglected for above forty years.

At length Barrow contrived to ſubſtitute for theſe vaniſhing quantities of Fermat others ſuppoſed infinitely ſmall. In 1674, he gave his method of tangents, which is only a geometrical conſtruction of the method of Fermat, by means of a triangle infinitely ſmall, formed by the ſides e and $\frac{ey}{t}$, and by an infinitely ſmall ſide of the curve ſuppoſed a polygon. With him originated the ſyſtem of infiniteſimal quantities, from which aroſe the differential calculus.

But to return to the ſubject. Queſtions relating to the maxima and minima of quantities were not unknown to the ancient geometricians. One entire book of Apollonius is devoted to the inveſtigation of the longeſt and ſhorteſt lines that can be drawn from a given point to the arcs of conic ſections. The method of Apollonius is reduced ſimply to the proof, that every other ſtraight line drawn to the conic ſection is leſs in caſe of the maximum, and greater in that of the minimum, than that which he has determined, and this method has ſince been generally followed by all thoſe who have endeavoured to ſolve theſe problems by ſimple geometry.

Fermat, as above ſtated, was the firſt who attempted to ſolve them analytically. His method, ſimplified and generalized by the fluxionary and differential calculus, conſiſts in making the differential or fluxion of the function, which is to be a maximum or minimum, equal to zero. Moſt of the methods we have been treating of derive their origin from the conſideration of curve lines; the determination of the greateſt and leaſt ordinates in curved lines and ſurfaces gave riſe to the above queſtions of *maxima* and *minima*. But there is a ſpecies of problems, related to theſe, of a much more difficult and general nature, and though our limits will not permit us to devote a very great portion of this work to them, yet we would not willingly omit a general illuſtration of the principle on which they depend. The problem of the *ſwifteſt deſcent* is of this nature; and was one of the firſt that was attempted. In theſe queſtions it is required to inveſtigate curves in which quantities, depending on the whole extent of the required curve, taken between certain limits, are a maximum or minimum, relative to all other poſſible curves, as for example, the curve which encloſes the greateſt ſpace according to ſome given conditions. There are many problems in mechanics of this nature. Newton firſt inveſtigated the nature of the curve which, by revolving on its axis, produced the ſolid which oppoſed the leaſt poſſible reſiſtance to a fluid moving in the direction of its axis. Though ſome of theſe problems had been occaſionally ſolved in particular inſtances, yet no general rule had been found applicable to them, till Lagrange deviſed the method known by the name of calculus variationum.

The firſt methods attempted towards the ſolution of theſe problems was, according to the differential notion, by dividing the curve into an infinite number of polygons, then determining the poſition of two adjacent ſides, ſo that the quantity propoſed becomes a maximum or minimum, by making the ordinate only vary according to the angle formed by the two ſides. By this contrivance the problem is reduced to the former claſs, and the only difficulty is to bring the reſult to the differential form. It was thus found that the curve of the quickeſt deſcent was ſuch, that the ſine of the angle which one of its infinitely ſmall ſides makes with the vertical, muſt always be proportional to the velocity, which is as the ſquare root of the height from which the body has deſcended; and this proportion, reduced to a differential equation, gives the cycloid. This method was afterwards applied to problems ſtill more complicated, particularly to thoſe called *iſoperimetrical*, in which it was required to find among all the curves having a given perimetre, that which within certain limits ſhould contain the greateſt or leaſt ſurface; and from the difficulty of theſe problems, joined to the celebrity which they acquired by the labours of Euler and the Bernouillis, the general name of iſoperimetrical was given to them, even in the caſe where the condition of equality in the length was not required.

In all the preceding inveſtigations relative to maxima and minima, when z has been ſuppoſed a function of x, y; x and y have been ſuppoſed to have ſome conſtant relation to each other during the courſe of the problem, but in many problems, particularly in thoſe under conſideration, theſe relations are ſuppoſed continually to change. In a given curve for inſtance, x and y and dx, and dy have a relation to each other defined by the nature of the curve, but in the method of variations, the ordinates y are no longer bounded by the original curve, but may paſs into another, having no determinate relation with the former.

Let

Let V denote ſome function of x and y, and of the differential co-efficients of y, then the value of x remaining the ſame, the integral $\int . V . dx$ is ſuſceptible of an infinity of values, depending on the relation between x and y. It may therefore become a queſtion, among all the poſſible relations of x and y, to determine that, in which the integral $\int V dx$ (between certain limits) is a maximum or minimum; the integral $\int V dx$, when no particular relation between x and y is ſpecified, expreſſing the meaſure of a property belonging to all curves, it is required to determine the curve in which this property is a maximum or minimum. It is evident that if C E (*fig.* 8.) repreſent this curve, then in any other, $\gamma\varepsilon$, the integral $\int V dx$ muſt be a value greater in the firſt caſe and leſs in the ſecond. To ſatisfy this condition, we muſt firſt inveſtigate the difference which any given change in the relation of x to y will make in the integral $\int V dx$; this change will be expreſſed by making y vary independently of x, for in conſidering the two curves C E, $\gamma\varepsilon$, the ſame abſciſſa A P correſponds to two ordinates P M, P μ, and their difference, M μ, ſhould be diſtinguiſhed from the differences M R, $\mu\varphi$, which take place between the conſecutive ordinates taken on the ſame curve.

In the calculus of variations as deviſed by La Grange, a differential equation, formed by conſidering the quantities as varying in one certain relation, is made the primitive of a new differential equation in which the quantities are ſuppoſed to vary in a new relation: and an hypotheſis is eſtabliſhed upon this ſecond operation ſuited to the nature of the ſubject under inveſtigation. It is by the ſymbol δ that this new operation is denoted; and taking for illuſtration the ſame curve lines as above, d denotes the variation or tranſition from one point to another on the ſame curve; δ that made in conſequence of a point moving into ſome new curve: thus M R being repreſented by dy, M μ will be δy; hence

$$P'M' = y + dy;\ P\mu = y + \delta y.$$

The point M′ paſſing to the point μ', we ſhall have

$$P'\mu' = y + dy + \delta(y + dy)$$
$$= y + dy + \delta y + \delta dy,$$

and by comparing theſe two expreſſions of the ſame line, this remarkable equation is obtained,

$$\delta dy = d\delta y.$$

The ſame reſult may be obtained without any reference to the nature of curve lines, by repreſenting by φx the primitive ſtate of y, and by $\downarrow x$ the conſequence of the ſuppoſed variation. Then $\delta y = \downarrow x - \varphi x$, will be a certain function of x, and likewiſe a function of y, becauſe of the primitive relation between x and y; let π denote this latter function, then $\delta y = \pi y$; let $y + dy = y'$; then $\delta y' = \pi y'$: hence $\delta y' - \delta y = \pi y' - \pi y = d\pi y = d\delta y$: but $dy = y' - y$, taking the variations

$$\delta dy = \pi y' - \pi y; \text{ hence } \delta dy = d\delta y.$$

In like manner $\delta d^2 y = d^2 \delta y$, and generally $\delta d^n y = d^n \delta y$, by which it appears that the ſymbols d and δ may always be tranſpoſed.

The principle of La Grange's method conſiſts in taking the differentials of x, y, dx, dy, &c. according to the uſual proceſs, but relatively to another characteriſtic or ſymbol δ different from d, uſed in the firſt caſe; then tranſpoſing δ after d and $\int$, if it happen to precede them, and making δx, δy, &c. diſappear by integration from under the ſign $\int$.

Let the formula, which within certain limits is to be a maximum or minimum, be $\int z$, a function of x, y, dy, &c. Suppoſing dx conſtant, then $\delta . \int z$ will be the differential value in the caſe of a maximum or minimum; therefore

$$\delta . \int z = 0, \text{ which may be transformed into } \int dz = 0.$$

Let the differential of this equation, found in the uſual manner, but with the ſymbol δ, be

$$\delta z = M\delta y + N\delta dy + P\delta d^2 y + \&c.;$$
$$\text{then } \int M\delta y + \int N\delta dy + \int P\delta d^2 y + \&c. = 0.$$

But $\int N\delta dy$ may be transformed into $\int N d\delta y$, and then by integration into

$$N\delta y - \int dN\delta y.$$

In the ſame manner $\int P\delta d y$ is transformed firſt into $\int P d^2 \delta y$; then into $P d\delta y - dP\delta y + \int d^2 P\delta y$, and ſo of the others.

Adding the conſtant quantity k, or correction to theſe integrations, the equation becomes

$$N\delta y + P d\delta y - dP\delta y + \&c. + k$$
$$+ \int (M - dN + d^2 P - \&c)\delta y = 0.$$

As all the differentials of δy have diſappeared from under the ſign $\int$, this part is not ſuſceptible of farther reduction. Therefore, to verify the equation independently of the variations, the co-efficient of δy under the ſign $\int$ muſt be made $= 0$, which gives the following equation,

$$M - dN + d^2 P - \&c. = 0;$$

which equation muſt ſubſiſt for all the values of x and y contained within the given limits.

Example.—Let it be required to aſſign the relation between x and y when $\sqrt{dx^2 + dy^2}$ is a minimum, which is equivalent to finding the ſhorteſt diſtance between two points,

$$\delta\sqrt{dx^2 + dy^2} = \frac{dx\delta dx + dy\delta dy}{\sqrt{dx^2 + dy^2}},$$

(which, ſuppoſing $ds = \sqrt{dx^2 + dy^2}$)

$$= \frac{dx d\delta x}{ds} + \frac{dy d\delta y}{ds}$$

Here $M = 0,\ N = \frac{dx}{ds},$

$$m = 0,\ n = \frac{dy}{ds},$$

$$M - dN = -d . \frac{dx}{ds} = 0,$$

$$m - dn = -d . \frac{dy}{ds} = 0.$$

Therefore $\frac{dx}{ds} = a$, a conſtant quantity,

$$\frac{dy}{ds} = b, \text{ a conſtant quantity.}$$

or $x : y :: a : b$, an equation to a ſtraight line.

We ſhall conclude this article with Mr. Woodhouſe's method of applying theſe principles to the inveſtigation of the properties of motions, which we particularly wiſh to recommend to the notice of the mathematical reader.

Let the relation between the ſpace x, and time t, be denoted by $x = \varphi t$, then t being increaſed to $t + \Delta t$, $x + \Delta x = \varphi(t + \Delta t) = \varphi t + D\varphi t . \Delta t + \overset{D^2}{c}\varphi t . (\Delta t)^2 + \&c. = x + D . x . \Delta t + \overset{D^2}{c} . x . (\Delta t)^2 + \&c.$ and conſequently $\Delta x = D . x . \Delta t + \overset{D^2}{c} . x . (\Delta t)^2 + \&c.$ let moreover the relation between any other ſpace, y, and time t, be denoted by $y = ft$, then $\Delta y = f(t + \Delta t) - ft = Dft . \Delta t + \overset{D}{c} ft . (\Delta t)^2 + \&c. = D . y . \Delta t + \overset{D^2}{c} . y . (\Delta t)^2 + \&c.$ Now, if $x = y$, $D . x = D . y$, $D^2 . x = D^2 . y$, &c. $D^{n-1} . x = D^{n-1} . y$, then the motion of the body deſcribing the ſpace Δy, approaches more nearly to the motion of the body deſcribing the ſpace Δx,

than can any other motion designated by an equation as $v = \downarrow t$, except $D \cdot v = D \cdot x$, $D^2 \cdot v = D^2 \cdot x \ldots$ &c. $D^{n-1} \cdot v = D^{n-1} \cdot x$; for, suppose it otherwise, then, since the motion to which corresponds $v = \downarrow t$, approaches more nearly to the motion to which corresponds $x = \varphi t$, than the motion to which corresponds $y = f t$, $\Delta x - \Delta v$ ought to be less than $\Delta x - \Delta y$, however small the time Δt be, or $(D \cdot x - D \cdot v)\, \Delta t + (\overset{c}{D^2} \cdot x - \overset{c}{D^2} \cdot v)\, (\Delta t)^2 +$ &c. (1) ought to be $< (\overset{c}{D^n} x - \overset{c}{D^n} \cdot y)\, (\Delta t)^n + (\overset{c}{D^{n+1}} \cdot x - \overset{c}{D^{n+1}} \cdot y)\, (\Delta t)^{n+1} +$ &c. (2) however small the element Δt be taken, which is clearly impossible, except $D \cdot x = D \cdot v$, $D^2 \cdot x = D^2 \cdot v$, &c. and $D^{n-1} \cdot x = D^{n-1} \cdot v$, for if these differential co-efficients up to the n^{th} are not equal, the first term of series (1), must contain a power $\left((\Delta t)^{n-m}\right)$ of Δt less than $(\Delta t)^n$, and consequently, dividing by $(\Delta x)^{n-m}$, for $\Delta x - \Delta v$ to be less than $\Delta x - \Delta y$, $(\overset{c}{D^{n-m}} \cdot x - \overset{c}{D^{n-m}} \cdot v) + (\overset{c}{D^{n-m+1}} \cdot x - \overset{c}{D^{n-m+1}} \cdot v) \cdot \Delta t +$ &c. must be $< (\overset{c}{D^n} \cdot x - \overset{c}{D^n} \cdot y) \cdot (\Delta t)^m + (\overset{c}{D^{n+1}} \cdot x - \overset{c}{D^{n+1}} \cdot y) \cdot (\Delta t)^{m+1} +$ &c. which, as has been shewn before, is impossible.

To apply this proposition to particular instances; let the equation between y and t be thus expressed, $y = a t$, a being a constant quantity, in which case the spaces are proportional to the times, and the motion is said to be uniform; then making $y = x = a t$, $\frac{d x}{d t}$ or $D \cdot x = a$, consequently there is no other uniform motion which can approach so nearly to the motion, to which corresponds $x = \varphi t$, as that to which corresponds the equation $y = \frac{d x}{d t} \cdot t$: for if possible, let $v = \alpha t$, then $v = x = \alpha t$, and $v = \frac{d x}{d t} \cdot t$, the same equation as before.

The constant quantity a in the equation $y = a t$ is the measure of what is called the velocity, and consequently in the equation $x = \varphi t$ the co-efficient $\frac{d x}{d t}$ may be called the velocity of the body in motion, or, if the body moved uniformly with a velocity measured by the co-efficient $\frac{d x}{d t}$, it would have the property above specified, namely, that the space described by it, for a certain value of (Δt) and for all lesser values, will differ less from the entire space (Δx), than the space described in any other uniform motion, depending on a different element, or measure (α) of the velocity.

As a second example, let $y = b t^2$, b being constant, in which motion, the spaces described from rest, vary as the squares of the times, make $y = x = b t^2$, therefore $\frac{d x}{d t} = 2 b t$, and $\frac{d^2 x}{2 \cdot d t^2} = b$, consequently, by what has preceded, the motion designated by the equation $y = \frac{d^2 x}{2 \cdot d t^2} \cdot t^2$ is (at the point where $y = x$, and $\frac{d y}{d t} = \frac{d x}{d t}$) more nearly equal the given motion $(x = \varphi t)$ than any other motion designated by a similar equation to the equation $y = b t^2$; for assuming $v = \beta t^2$ it appears, that $\beta = \frac{d^2 x}{2 \cdot d t^2}$, whence $v = \frac{d^2 x}{2 \cdot d t^2} \cdot t^2$, the same equation as has been deduced.

In the equation $y = b t^2$, in which the motion of the body is accelerated, the element b is the measure of what is called the accelerating force; and agreeably to such imposition of terms, the accelerating force belonging to a motion $x = \varphi t$, is equal $\frac{d^2 x}{2 \cdot d t^2}$ or has the property above specified; and moreover, when the accelerating force is required to be calculated, it is simply the co-efficient $\frac{d^2 x}{2 \cdot d t^2}$ that is to be estimated: the term itself has been introduced from the disposition men have to speak of the causes of effects, although it is clear, that by imposing a mere term on an effect, nothing is taught concerning the cause of that effect; when the term occurs, nothing more is to be understood by it, than the specification of an effect, that is, the uniform acceleration of the body's motion, or what amounts to the same, the continual and uniform augmentation of the velocities, the measure of velocity being a space described in a given time.

Hence, in the form $\Delta x = \frac{d x}{d t} \cdot \Delta t + \frac{\overset{c}{d_2} x}{d t^2} \cdot (\Delta t)^2 + \frac{\overset{c}{d_3} x}{d t^3} \cdot (\Delta t)^3 +$ &c. the whole space (Δx) may be conceived composed of a number of spaces due to particular kinds of motion; the first term $\frac{d x}{d t} \cdot \Delta t$ is the space described in uniform motion with a velocity $= \frac{d x}{d t}$, the second $\frac{\overset{c}{d_2} x}{d t^2} \cdot (\Delta t)^2$ is the space described in motion uniformly accelerated, the quantity of the acceleration depending on the co-efficient $\frac{\overset{c}{d_2} x}{d t}$, the third term $\frac{\overset{c}{d_3} x}{d t^3} \cdot (\Delta t)^3$ is another space due to a motion, the kind of which has not been described in terms as the two former have, because no such motion occurs in nature: its laws, however, are defined with the same precision as the laws of uniform, and uniformly accelerated motion: a like observation is to be extended to the other spaces $\frac{\overset{c}{d_4} x}{d t^4} \cdot (\Delta t)^4$, $\frac{\overset{c}{d_5} x}{d t^5} \cdot (\Delta t)^5$, &c.

Since the velocity $(V) = \frac{d x}{d t}$ and accelerating force $(F) = \frac{d^2 x}{2 \cdot d t}$, $F = \frac{1}{2 \cdot d t} d \left(\frac{d x}{d t}\right) = \frac{1}{2 \cdot d t} \cdot d V$, or $2 F \cdot d t = d V$, and $2 F \cdot d t \cdot \frac{d x}{d t} = V d V$, whence, if F be given a function of the time (t) the integral of $V d V$, to wit, $\frac{V^2}{2}$ may be exhibited by a function likewise of the time; and by making t a function of x, $\frac{d x}{d t} = \frac{1}{\frac{d t}{d x}}$, $\left(\frac{d x}{d}\right.$ $\left.\frac{d t}{d x}\right)$, representing the differential co-efficients of x a function of t, and of t a function of x) the expression becomes $\frac{1}{2 F \cdot d x}$

$2\,F\,.\,d\,x = V\,d\,V$, whence F being given a function of the pace V^2 may be deduced a function.

Since $\Delta\,x = \frac{d\,x}{d\,t}\,.\,\Delta\,t + \frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}\,.\,(\Delta\,t)^2$ + &c. if the body fall from reſt, or the velocity $\frac{d\,x}{d\,t} = 0$, then $\Delta\,x = \frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}\,.\,(\Delta\,t)^2 + \frac{d^3\,x}{1\,.\,2\,.\,3\,.\,d\,t^3}\,.\,(\Delta\,t)^3$ + &c. now ſince $\Delta\,t$ may be taken ſuch, that $\frac{d^3\,x}{1\,.\,2\,.\,3\,.\,d\,t^3}$ ſhall be greater than the ſum of all ſucceeding terms, ſo that $\left(\frac{d^3\,x}{1\,.\,2\,.\,d\,t^2} + \frac{d^4\,x}{1\,.\,2\,.\,3\,.\,d\,t^3}\,.\,\Delta\,t + \text{\&c.}\right) < \left(\frac{d^3\,x}{1\,.\,2\,.\,d\,t^2} + \frac{2\,.\,d^3\,x}{1\,.\,2\,.\,3\,.\,d\,t^3}\,.\,\Delta\,t\right)$ and à fortiori, leſs, for all leſſer values of $\Delta\,t$, it is clear, that by taking $\Delta\,t$ of a proper ſmallneſs, $\left(\frac{d^2\,x}{1\,.\,2\,.\,d\,t^2} + \frac{2\,.\,d^3\,x}{1\,.\,2\,.\,3\,.\,d\,t^3}\,.\,\Delta\,t\right)\,(\Delta\,t)^2$ may be made to differ from $\frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}\,.\,(\Delta\,t)^2$ by a difference leſs than any aſſignable quantity.

This is all that is to be underſtood in the preſent method, concerning an equality that is ſaid to ſubſiſt between the ſpaces deſcribed in initio motus, the ſquares of the times, and other conſtant quantities.

As, in the caſe of tangents and radii of curvature, the analytical properties were firſt ſtated and the geometrical deduced, ſo, in the caſe of velocities and accelerating forces, the analytical properties being firſt ſtated, the mechanical properties (if they may be ſo called) have been deduced; and a reverſe proceſs, it is evident, may be inſtituted; thus, defining the meaſure of the velocity of a body in variable motion, at a given point, to be a quantity, ſuch, that if the body moved uniformly, (the kind of uniform motion being determined by that conſtant quantity) the ſpace deſcribed would be nearer the entire ſpace ($\Delta\,x$), than any other ſpace deſcribed by another uniform motion, the velocity may be deduced; thus, let a be its meaſure, then the ſpace deſcribed in the time $\Delta\,t = a\,.\,\Delta\,t$, and $\Delta\,x$ being $= \frac{d\,x}{d\,t}\,.\,\Delta\,t + \frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}(\Delta\,t)^2$ + &c.

$\left(\frac{d\,x}{d\,t} - a\right)\Delta\,t + \frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}\,.\,(\Delta\,t)^2$ + &c. is $<$ $\left(\frac{d\,x}{d\,t} - \alpha\right)\Delta\,t + \frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}\,.\,(\Delta\,t)^2$ + &c. which cannot be generally aſſerted; for, make the conſtant quantity $\alpha = \frac{d\,x}{d\,t}$, then $\Delta\,t$ may be taken ſo ſmall, that $\frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}\,.\,(\Delta\,t)^2$ + &c. ſhall be $< \left(\frac{d\,x}{d\,t} - \alpha\right)\Delta\,t + \frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}\,.\,(\Delta\,t)^2$ + &c. but if $\frac{d\,x}{d\,t} = a$, then can $\left(\frac{d\,x}{d\,t} - a\right)\,.\,\Delta\,t$ + &c. be $< \left(\frac{d\,x}{d\,t} - \alpha\right)\Delta\,t + \frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}\,.\,(\Delta\,t)^2$ + &c. whilſt $\frac{d\,x}{d\,t}$ does not equal α, and conſequently, the element a put for the velocity, muſt $= \frac{d\,x}{d\,t}$.

In like manner taking the definition that has been given of the accelerating force, its value may be ſhewn equal $\frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}$.

The term velocity has cauſed much confuſion of ideas; its meaſure is the conſtant quantity expreſſing the ratio between the ſpace and time in uniform motion; in the equation $x = a\,t$, it is a, which element ſerves to diſtinguiſh one uniform motion from another; in variable motion, the meaſure of the velocity is $\frac{d\,x}{d\,t}$; and this only is meant, that a body moving uniformly with this velocity $\frac{d\,x}{d\,t}$, would deſcribe a ſpace $\frac{d\,x}{d\,t}\,.\,\Delta\,t$, which has the conditions above ſpecified: a like explanation is to be given of the term *accelerating force* in variable motion; when the accelerating force is ſaid to vary as a function ($f\,x$) of the ſpace deſcribed, what is to be underſtood, is, that the co-efficient $\frac{d^2\,x}{d\,t^2}$ varies as $f\,x$.

The ſpace $\Delta\,x = \frac{d\,x}{d\,t}\,.\,\Delta\,t + \frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}\,(\Delta\,t)^2$ + &c. and conſequently, $\frac{\Delta\,x}{\Delta\,t} = \frac{d\,x}{d\,t} + \frac{d^2\,x}{1\,.\,2\,.\,d\,t^2}\,.\,\Delta\,t$ + &c. now by what has appeared, $\frac{d\,x}{d\,t}$ may be made to differ from $\frac{\Delta\,x}{\Delta\,t}$ by a quantity leſs than any aſſignable quantity; and this is all that is clearly intelligible concerning any *equality* that can ſubſiſt between $\frac{d\,x}{d\,t}$ and a certain ſtate of $\frac{\Delta\,x}{\Delta\,t}$; in the language of limits, the limit of $\frac{\Delta\,x}{\Delta\,t}$ or L. $\frac{\Delta\,x}{\Delta\,t}$ is ſaid to equal $\frac{d\,x}{d\,t}$.

The definition of velocity being given, to determine its quantity, or meaſure in variable motion, becomes a matter of computation: and x being a function of the time, the differential co-efficient $\frac{d\,x}{d\,t}$, the meaſure of the velocity muſt be computed, which, by preceding methods, can always be effected; but the differential co-efficient, or what correſponds to it, may be eſtimated by ſeveral methods, although the principle on which they are founded is in fact the ſame; hence computing by ſuch methods the velocity, the quantity deduced muſt be what, really, $\frac{d\,x}{d\,t}$ is; not ſimply the firſt differential co-efficient of $x + \Delta\,x$ expanded, but the firſt differential co-efficient obtained by a particular hypotheſis; now the method the fluxioniſts have followed is this; they define fluxions to be velocities, and having, by certain proceſſes, obtained the quantity ſymbolical of the velocity, they, in fact, had obtained the fluxion or differential of a quantity: a procedure, it ſhould ſeem, not very philoſophical; ſince velocity, as a term by which fluxions are

defined, itſelf in variable motion, wants definition, and, as a principal, wants computation. And when, as has been already ſtated, a partial theory, itſelf to be included under the general theory of quantity, was employed to illuſtrate that theory, correſponding modes of conceiving quantity, and expreſſions to reaſon about quantity, became neceſſary: every thing that could become the ſubject of inveſtigation was to be conceived as generated by motion, or its increaſe to be analogous to the deſcription of right lined ſpace by a moving body; figurative expreſſions entered as parts of this theory, and the ſevere ſciences were diſcuſſed in terms and phraſes new to geometry.

Science, however, derived an incalculable advantage from the invention of the method of fluxions, but the excellence of this invention, one of the foundation ſtones of the immenſe fabric of Newton's fame, does not conſiſt in the principle by which quantity was conceived to be generated by motion, but in the proceſſes and rules by which it was taught, how the properties of motion might be inveſtigated, and conſequently, the ſimilar properties of continued quantity; in the ſimple excogitation of the principle of motion, Newton had been preceded by Roberval.

According to the view that has been taken of the differential calculus, it is to be conſidered as a branch of common algebra, or rather as a part of the common ſymbolical language in which quantity is treated of. In its mere proceſſes and rules it demands no hypotheſis, it requires the eſtabliſhment of no theory; the differential of $f x$ is ſimply the ſecond term of $f(x + \mathrm{d}\,x)$ expanded, $\mathrm{d}\,x$ being altogether arbitrary; and in particular caſes, as x^m, a^x, $\mathrm{L}\,.\,x$, &c. comprehended by $f\ x$, $m\,x^{m-1}\,\mathrm{d}\,x$, $\mathrm{A}\,a^x\,\mathrm{d}\,x$, $\frac{\mathrm{d}\,x}{\mathrm{A}\,x}$, &c. In its application, the calculus cannot be ſaid to demand any new hypotheſis, but ſimply requires this propoſition to be eſtabliſhed, *viz.* that in a ſeries $a + a'\,.\,x + a''\,.\,x^2 +$ &c. x may be taken of ſuch a magnitude, that any term, as $a'^{\cdots n}\,x^n$, ſhall be greater than ſum of all the ſucceeding terms. In the method of fluxions and of limits, the differential (or fluxion) of a function $f\ x$, although expreſſed by the ſecond term of $f(x + \mathrm{d}\,x)$, or $f(x + \dot{x})$ expanded, is not ſimply that ſecond term, but is expreſſed by it, under the circumſtances of a particular hypotheſis and of a particular theory; and conſequently, the mere analytical proceſſes and operations by which rules are founded become burthened with that theory.

Function, in *Phyſiology*, the office in the animal economy performed by any part of the body. In this ſenſe it is ſynonymous with the *uſe* of the part; we ſpeak of the function of the kidney, teſtis, &c. The term, however, is employed, more extenſively, to denote the great proceſſes of the living body, the performance of which requires the co-operation of many organs; as thoſe of digeſtion, ſenſation, &c. Theſe ſubjects will all be conſidered under their reſpective articles in the Cyclopædia. We have given here a view of the different functions, arranged in the form of a table, ſo as to exhibit their mutual relations, and to afford alſo a general claſſification of the ſubjects belonging to phyſiology. This table is taken from the elements of phyſiology of Richeraud. We do not attach any great importance to the peculiar mode of the arrangement: all ſuch diviſions muſt be in great meaſure arbitrary. The various parts of the living ſyſtem are connected together; the functions are mutually dependent, ariſe out of each other, and are executed ſimultaneouſly. They repreſent altogether a circle, in which we cannot aſſign a beginning or an end. Digeſtion, abſorption, circulation, the ſecretions, nutrition, ſenſation, motion, the voice, and even generation, may be all going on at once; but an obſerver would find himſelf much confuſed by attending at the ſame time to all this aſſemblage of proceſſes. Again, when he proceeds to the work of abſtraction, when he begins to contemplate ſome ſingle part of the vital phenomenon, he muſt not look upon this as inſulated or independent, but advert to its connection with other parts of the economy. A more detailed view of theſe matters will be exhibited in the article Life.

The older writers divide the functions into four claſſes, called the animal, vital, natural, and generative. The firſt of theſe includes the ſenſations and motions, which form the diſtinguiſhing characters of animals; the ſecond, the proceſſes of circulation and reſpiration, the continuance of which is neceſſary to life; the third, digeſtion, chylification, abſorption, urinary ſecretion, &c. by which the nouriſhment and growth of the body are performed; and the fourth, thoſe proceſſes by which the continuance of the ſpecies is provided for. Such an arrangement is very arbitrary, and open to numerous objections. The vital and animal functions are ſometimes claſſed together under the former name. Vicq d'Azyr has prefixed an arrangement of functions to his great work, the "Traité d'Anatomie avec des plauches colorieés." This is objectionable, ſince ſenſibility, irritability, and oſſification, are there included. Now the two former are the powers or properties by which certain parts are enabled to perform their functions, and the latter is merely a mode of nutrition peculiar to a certain ſtructure of the body.

TABULAR View of the Functions of the Animal Economy.

- **First Class.** FUNCTIONS CONCERNED IN THE PRESERVATION OF THE INDIVIDUAL. (*Life of the individual.*)
  - **First Order.** By assimilating food to his own substance. (*Interior, assimulative, or nutritive functions.*)
    - First Genus.—DIGESTION. Extracts from it the nutritive parts.
      - Prehension of the food,
      - Mastication
        - First dentition,
        - Second ditto,
      - Insalivation,
      - Deglutition,
      - Digestion in the stomach,
      - ——— duodenum,
      - ——— small intestine,
      - Excretion of fœces,
      - ——— urine.
    - Second Genus.—ABSORPTION. Conveys the nutritive matter into the blood.
      - Absorption of chyle,
      - ——— lymph,
      - Action of the absorbing vessels,
      - ——— glands,
      - ——— thoracic duct.
    - Third Genus.—CIRCULATION. Carries it to all the organs.
      - Action of the heart,
      - ——— arteries,
      - ——— capillary vessels,
      - ——— veins.
    - Fourth Genus.—RESPIRATION. Exposes it to the atmosphere.
      - Action of the parietes of the chest,
      - ——— lungs,
      - Changes produced in the air,
      - ——— blood,
      - Production of animal heat.
    - Fifth Genus.—SECRETIONS. Make it undergo various modifications.
      - Formation of serum,
      - Follicular or mucous secretion,
      - Glandular secretion.
    - Sixth Genus.—NUTRITION. Applies to the organs, for the purposes of growth and nourishment.
      - Different in each part, according to its peculiar composition.
  - **Second Order.** By establishing his relations to surrounding objects. (*Exterior* or *relative functions.*)
    - First Genus.—The SENSATIONS. Give him notice of their presence.
      - Organs
        - of sight,
        - — hearing,
        - — smelling,
        - — tasting,
        - — touching,
      - Action of the nerves,
      - ——— brain,
      - Faculties of the mind,
      - Perception,
      - Memory,
      - Judgment,
      - Volition,
      - Sleeping and waking,
      - Dreams and somnambulism.
    - Second Genus.—The MOTIONS. Bring him towards, or remove him from them.
      - Muscles,
      - Muscular action,
      - The skeleton,
      - Articulations,
      - Erect position, or
      - Standing at rest,
      - Progressive motions
        - Walking,
        - Running,
        - Leaping,
        - Swimming,
        - Flying,
        - Creeping.
      - Motions of the upper limbs,
      - Attitude, Gesture.
    - Third Genus.—VOICE and SPEECH. Enable him to communicate with is fellows without moving.
      - Voice,
        - Articulated, or speech,
        - Modulated, or singing,
      - Lisping,
      - Stammering,
      - Dumbness,
      - Ventriloquism.

Second

- Second Claſs. FUNCTIONS CONCERNED IN THE PRESERVATION OF THE SPECIES. (*Life of the ſpecies.*)
  - First Order. Requiring the concourſe of both ſexes.
    - CONCEPTION and GENERATION.
      - Sexual diſtinctions,
      - Hermaphrodites,
      - Syſtems concerning generation.
  - Second Order. Performed by the female.
    - GESTATION.
      - Pregnant uterus,
      - Hiſtory of the embryo,
      - ——— fœtus,
      - ——— its coverings.
    - PARTURITION.
      - Uterus after parturition,
      - Diſcharge of the lochia.
    - LACTATION.
      - Office of the mammæ,
      - Milk.
    - AGE OF GROWTH.
      - Infancy
        - Dentition,
        - Oſſification.
      - Puberty — Menſtruation.
      - Adoleſcence.
    - AGE OF MANHOOD.
      - Differences of temperament,
      - Idioſyncraſies,
      - Different races of mankind.
    - AGE OF DECAY.
      - Period of decline,
      - Old age,
      - Decrepitude.
    - DEATH.
    - PUTREFACTION.

FUND, FUNDUS, a Latin term, uſed for the bottom of certain things; and particularly of certain parts of the body.

FUND *of the eye*, *Fundus oculi*, is that part poſſeſſed by the choroides and retina.

The images of objects are repreſented in an inverted ſituation, in the fund of the eye. See VISION.

FUNDUS *Uteri*, or *bottom of the womb*, is the body or principal part thereof; ſo called in contradiction to the cervix, or neck; the oſculum, or mouth; and the vagina, or ſheath.

FUNDUS *Veſicæ*, or *bottom of the bladder*, is the cavity thereof, wherein the urine is contained. In men it is placed over the rectum; and in women over the matrix.

FUND *of the Gall-bladder*, the *Stomach*, &c. See GALL-*bladder*, STOMACH, &c.

FUNDUS *Plantæ*, is that part of a plant where the ſtalk juſt meets and joins the root.

FUNDUS *Cæli*, is the point oppoſite to the point of culmination; or the point of the ecliptic, wherein it is interſected by the meridian beneath the horizon.

FUND, in *Commerce*, is uſed for the capital or ſtock of a merchant, company, or corporation; or the ſum of money they put into trade.

In this ſenſe we ſay abſolutely, the funds, the public funds, meaning the ſtock of the great companies, or corporations, as the Bank, South-ſea, Eaſt-India, &c.

FUNDS, *Public*, are the taxes appropriated by parliament to the ſupport of civil government, and the payment of the principal and intereſt of money borrowed for public ſervices. Theſe funds, in Britain, have been all formed into the four following claſſes or diviſions: the *Aggregate Fund*, the *South-ſea Fund*, the *General Fund*, and the *Sinking Fund*. Of all theſe, but more eſpecially the laſt, we ſhall give an account in the order in which they have been now named.

The aggregate fund was eſtabliſhed by an act of Geo. I. cap. 12. in 1715. It had this name given it, becauſe it conſiſted of a great variety of taxes and ſurpluſſes of taxes and duties which were in that year conſolidated, and given as a ſecurity for the diſcharge of the intereſt and principal of debts due to the Bank of England, and ſome other public debts; and alſo for the payment of 120,000*l.* per ann. to the civil liſt. Into this fund were brought the two-thirds and one-half ſubſidy of tonnage and poundage; half the inland duties on tea and coffee; the houſe-money granted by the 7th of Will. III.; the duty on hops; the duties on low wines, brandy, and Britiſh ſpirits; all arrears of land-taxes; all public monies not appropriated; the ſurpluſſes of the nine-penny exciſe, of the five-ſevenths of the Bank nine-penny exciſe, of the revenues in the annuity acts of the 4th, 5th, and 6th of queen Anne, &c. and by an act of the 1ſt of Geo. III. all the duties conſtituting the revenue of the civil liſt.

The South-ſea fund was eſtabliſhed by ſtat. 3 Geo. I. cap. 9. in 1716; and was ſo called, becauſe appropriated to pay the intereſt of the South-ſea company's capital. It conſiſted of a duty on candles, and certain impoſts on wines, vinegar, tobacco, and Eaſt-India goods.

The general fund was alſo eſtabliſhed by ſtat. 3 Geo. I. cap. 7. in 1716, and conſiſted of a ſubſidy on goods exported; a tax on hackney-coaches and chairs; duties on ſoap, hides, ſtamps, and policies of inſurance; 700*l.* per week letter-money; a moiety of the inland duties on tea and coffee; and 39,855*l.* per annum out of the hereditary exciſe on beer for the bankers annuities. All theſe taxes were appropriated to the diſcharge of the intereſt of 7,808,087*l.* (originally 10,000,000*l.*) capital ſtock of South-ſea annuities, together with charges of management.

All that remained of the produce of the taxes thus digeſted into theſe three funds, after ſatisfying the charges upon them, was in the ſame year (or 1716) carried into a fourth fund, to which was given the name of the ſinking fund, becauſe appropriated to the *ſinking* of the public debts. The words of the act of the 3d of Geo. I. which eſtabliſhed this fund, are, "All the monies to ariſe from time to time, as well of the exceſs and ſurplus of an act made this ſeſſion for redeeming the funds of the Bank of England; and of the exceſs or ſurplus by virtue of one other act made likewiſe this ſeſſion for redeeming the funds of the South-ſea company; as alſo of the exceſs or ſurplus of the duties and revenues by this act appropriated as aforeſaid; and the overplus monies of the ſaid general fund by this act eſtabliſhed; ſhall be appropriated to the diſcharging the principal and intereſt of ſuch national debts as were incurred before the 25th of December, 1716, and are declared to be national debts;

debts; and to or for no other uſe, intent, or purpoſe whatſoever."

The tranſactions, with reſpect to this ſinking fund, form ſo important a part of the hiſtory of Britain, that it may not be improper here to give a more particular account of it.

Before its eſtabliſhment there had exiſted many ſmaller funds of the ſame nature: that is, ſuch duties or taxes had been provided for paying the intereſts of particular loans, as afforded ſurpluſſes by which the principal itſelf was to be gradually redeemed. This was the common practice in the reigns of king William and queen Anne. Moſt of the public duties were given for terms of years; and at the end of thoſe terms they ceaſed of courſe, unleſs continued for farther terms by new acts of parliament: and, in general, it was provided, when any money was raiſed, that the principal ſhould be cancelled either by time, as in the caſe of the ſale of long and ſhort annuities, or by the ſurpluſſes of the duties charged with the payment of the intereſt. This was an excellent plan; but it was by no means carried ſteadily into execution. In the year 1720, moſt of the long and ſhort annuities were converted into redeemable perpetuities, at the expence of above three millions; and the ſurpluſſes of the duties charged with particular loans were often ſo broken into, by being either charged with new loans before they had cancelled the old, or ſpent on current ſervices, as to be rendered incapable of anſwering the end intended by them. In conſequence partly of this bad management, the public debts at the acceſſion of the houſe of Hanover were ſo much increaſed as to be generally reckoned inſupportable: and their reduction was made one of the firſt objects of parliamentary attention. This gave riſe, in 1716, to the inſtitution of the fund of which we are giving an account, the father of which was (as has been generally ſaid) ſir Robert Walpole, but, in reality, the earl Stanhope. All the taxes, except the land-tax, and ſix-pence per buſhel malt-tax, were now made perpetual, and diſtributed into the three funds which have been deſcribed; the ſurpluſſes of which, for ever afterwards, were to be held ſacred, and to be applied inviolably, according to the words of the act juſt recited, to the redemption of the national debt.

A conſiderate perſon might have ſuſpected, that the ſame cauſes which had rendered former partial appropriations ineffectual, would deſtroy the efficacy of this. There ſeemed, however, to be reaſon for hoping the contrary: for,

Firſt, the future happineſs and glory of the kingdom were thought to depend on this appropriation; and the law which eſtabliſhed it was declared to be a fundamental law of the realm. Secondly, in conformity to theſe ſentiments, the words of this law were made as ſtrong as poſſible; and, in order to give additional force to it, a repetition of it in the ſame words, was inſerted in an act of the 5th of Geo. I. cap. 3. Particular notice ſhould be taken of theſe words: they order that all the ſurpluſſes of the taxes then made perpetual ſhall be applied to the diſcharge of the public debts, and "to no other uſe or intent whatever." When, therefore, a debt had been paid off, the addition ariſing from that payment to the ſurpluſſes (or the annuity diſengaged by it) became a part of the fund, and, together with it, was to be employed in diſcharging farther debts. And the ſame being true of every ſucceſſive annuity diſengaged by every payment, the fund, if never miſapplied, muſt neceſſarily have operated in ſinking the public debt, in the ſame manner that money accumulates, when put out to bear compound intereſt. And in this way this fund did in fact operate for a few years. While in its infancy, it was watched over with great care. The improvement, and the inviolable application of it, were recommended in moſt of the ſpeeches from the throne, and echoed back in the addreſſes of the houſe of commons. It is particularly obſervable, that ſo well did our miniſters then underſtand the nature and importance of this fund, that rather than encroach upon it, they frequently borrowed money, in order to defray the neceſſary expences of government. From ſome publications in 1726 it appears, that ſome perſons had been led to apprehend this zeal of the miniſtry would not be permanent, becauſe it was not their intereſt to pay off the public debt, on account of the dependence and influence created by it. In anſwering this objection, the writers on the ſide of the court called ſuch an apprehenſion an *indecent jealouſy*, and took upon them to aſſure the public, "that in no poſſible exigence of affairs could our miniſters ever approve of or recommend the alienation of the ſinking fund." Happy would it have been for Britain had this proved true: but in a little time it appeared, that the apprehenſions which had been ſtiled *indecent jealouſies* were too well grounded. Men in power came ſoon to ſee, that this fund was advancing too faſt in its operations, and to change their zeal for it into a reſolution to deſtroy it. This will abundantly appear from the following facts.

Charging the income of the ſinking fund with the payment of the intereſt of new loans, is an encroachment upon it, no leſs ſubverſive of its efficacy, than depriving it of groſs ſums; there being no difference between taking from it the annual intereſt of a ſum, and that ſum itſelf. Between the years 1727 and 1732 ſeveral encroachments of this kind had been made upon it; but, being of a leſs obvious nature, they paſſed without meeting with any particular oppoſition. The finiſhing blow was given in the year 1733. In that year, in order to keep the land-tax at one ſhilling in the pound, it was neceſſary either to borrow half a million for the current ſervice, or to take this ſum from the ſinking fund. The laſt method was choſen, and propoſed by ſir Robert Walpole to the houſe of commons. Long and warm debates enſued. A propoſal to alienate, in a time of profound peace, a fund which the law had made ſacred, and the alienation of which no poſſible exigence of public affairs could juſtify, only for the ſake of keeping the land-tax for one year at one ſhilling in the pound, juſtly kindled the indignation of the patriotic party. They urged the prohibition of the law, the faith of parliament, and the ſecurity of the kingdom. The propoſer of the alienation was reminded of his inconſiſtency and treachery, in endeavouring to beat down that very monument of glory which he had boaſted of having erected for himſelf; and ſir John Barnard warned him, that he was drawing upon himſelf the curſes of poſterity. But all arguments were vain. The miniſtry pleaded that the landed intereſt wanted eaſe; that there was no occaſion for being in a hurry to pay the national debt; and that the circumſtances of the kingdom had altered ſo much ſince the eſtabliſhment of the ſinking fund, that the competition then among the public creditors was, not who ſhould be firſt, but who ſhould be laſt paid. Thus argued, among others, ſir Robert Walpole. His reaſons prevailed; and the houſe of commons, not uſed to refuſe him any thing, conſented.

The practice of alienating the ſinking fund having been thus begun, went on of courſe. In the next year, or 1734, 1,200,000*l.* was taken from it. In 1735, and 1736, it was anticipated and mortgaged.

In 1737 and 1738, a million of the ſtock of Bank annuities, and two millions of the ſtock of South-ſea annuities, were redeemed with it. For twelve years after 1738, it was wholly applied to the current expences of every year. In 1749, the intereſt of near fifty-eight millions of the public

public debts was reduced from four to three one-half per cent. intereſt for ſeven years, and afterwards to three per cent. for ever; and by this third reduction, an addition was made to the ſinking fund of near 600,000*l.* per ann. But notwithſtanding the great addition which this *third* reduction of intereſt made to the ſinking fund, no more than three millions of the public debts were redeemed by it, during the interval of peace between the years 1748 and 1756.

By an act of the 25th of Geo. II. 1752, a change was made in the ſinking fund, which it is neceſſary to mention.

Before this act the ſinking fund conſiſted only of the clear ſurpluſſes of the aggregate, the general, and the South-ſea company's funds. By the war, which begun in 1740, there was an addition made to the public debts of near thirty-two millions. This occaſioned a great increaſe of taxes; and the practice was, whenever any new tax produced leſs than the intereſt with which it was charged, to make good the deficiency out of the ſinking fund, and afterwards to replace the ſum taken from it out of the ſupplies for the following year. But whenever a tax produced more than the charge upon it, the overplus, inſtead of being carried to the ſinking fund, was made a part of the ſupplies for the year. By the act juſt mentioned, all the new taxes, together with all the annuities to the payment of which they had been appropriated, were ordered to be carried into the ſinking fund, and formed into one general account. Moſt of the new taxes having proved deficient, this fund at firſt loſt more than it gained by the change. But the loſs was afterwards more than made up; firſt, by the ſaving which was produced by the reduction of intereſt from three one half per cent., to three per cent. in 1757; and, ſecondly, by the addition, in the ſame year, of the ſalt-duties to this fund, after they had completed the redemption of a million with which they had been charged in 1745.

The war which began in 1756 added ſeventy-one millions and a half to the public debts. This produced a new increaſe of taxes, which (in conformity to the conſolidating act juſt mentioned) were brought to the general ſinking fund account, together with the annuities or intereſts with the payment of which they were charged. And previous to the American war it became the conſtant practice, whenever a new fund or tax was created for paying the intereſt of a loan, to carry both into the ſinking fund; in conſequence of which this fund gained when the tax happened to produce more, but loſt when it produced leſs than the intereſt which it had been given to pay. The ſinking fund, therefore, which, before the conſolidating act, conſiſted only of the ſurpluſſes of the aggregate, general, and South-ſea company's funds, conſiſted afterwards of the clear ſurplus of all the appropriated taxes. There was only one exception, namely, the additional tax upon houſes and windows, granted in 1758 towards paying the intereſt of four millions and a half then borrowed. This tax was never made a part of the ſinking fund; and, having always proved deficient to the amount of about 43,000*l.* per ann. the deficiency was conſtantly made good by the ſinking fund, and afterwards replaced from the ſupplies.

Before the laſt reduction of the intereſt of the public debts, the ſinking fund, having ſuffered greatly from various encroachments upon it, produced little more than a million per ann. But after this reduction, and its increaſe by the addition of the ſalt-duties, it produced near two millions per ann. In 1764 it produced at Michaelmas, after making good deficiencies, 2,105,000*l.* nearly. For five years after 1764, its average produce, reckoned to Chriſtmas in every year, was 2,234,780*l.* For five years, ended in 1774, its average produce (after making good the deficiency in 1758) was 2,610,759*l.* In 1775 it produced 2,917,869*l.* In 1776, 3,166,517*l.* In 1777 it was charged with an annuity of 100,000*l.* per ann. to the civil liſt; and, after paying three quarters of this annuity, and half a year's intereſt of five millions borrowed in that year, it produced from Oct. 1776 to Oct. 1777, 2,685,669*l.* From Oct. 1777 to October 1778, 1779, and 1780, it produced 2,442,063*l.*—2,267,399*l.*—and 2,403,017*l.* after paying the ſaid annuity, and alſo after making good the deficiency of the fund in 1758, and all the deficiencies of the new taxes.

It appears from this detail, that after the peace in 1763 the income of the ſinking fund increaſed conſiderably. The cauſes of this were partly the falling in of life-annuities, and the greater productiveneſs of the taxes occaſioned by the increaſe of luxury. But the principal cauſe was the falling in of the intereſt of about ten millions and a half of the public debts, which had been diſcharged during the twelve years of peace between 1763 and 1775. This diminution of the public debts was made, not by the ſinking fund, but by a contribution from the Eaſt-India company of 400,000*l.* per ann. begun in 1768, and continued for five years; by the profits of ten lotteries; by the compoſition for maintaining French priſoners; ſale of French prizes taken before the declaration of war in 1756; and other extraordinary receipts, amounting in all to above eight millions. This fund, therefore, did not pay off more than two millions and a half, the reſt of its produce having been employed in bearing the expences of the peace eſtabliſhment, which, during that period, were nearly double to what they had been in any former period.

To the ſum juſt mentioned, add three millions paid off in the peace between 1748 and 1756, and three millions paid off in 1736 and 1737, and it will appear that the whole amount of the public debts paid off by the ſinking fund, ſince its firſt alienation in 1733, to the commencement of the American war, was only eight millions and a half. Had no ſuch alienation ever taken place; had even *half* its annual produce been invariably applied to the purpoſe for which it was originally formed, the whole debt would have been redeemed, and the nation at that period would conſequently have been relieved from the whole burden of its taxes; and it is poſſible alſo that the whole expence of that calamitous war, and the loſs of the Britiſh colonies, would have been prevented. But the preſſure of theſe burdens having continued with equal force, during the whole interval of a peace of eleven years without the moſt diſtant proſpect of being diminiſhed by any prudence or economy in the management of public affairs, the nation ſuffered itſelf to be plunged into a war with the hope of being relieved from a part of its burdens, by compelling the coloniſts to bear a ſhare in the ſupport of them. Unfortunately, however, this war, like all that preceded it, inſtead of diminiſhing, increaſed the public burdens, ſo that the debt, which at its commencement amounted to 136 millions, had accumulated at its termination in 1783 to more than 268 millions. At this period the ſeveral changes in the miniſtry prevented any improvement from being made in the management of the public finances. The immediate ſucceſſors of lord North, if they had been ſo diſpoſed, had ſcarcely time to form any plan for the purpoſe; and the meaſures which had been recommended in the king's ſpeech, during the ſhort adminiſtration of the earl of Shelburne, were totally diſregarded by the party that followed him into power; ſo that it may be truly ſaid, that until the end of that adminiſtration the management of the finances was conducted

with the ſame diſregard to economy and the public intereſt, as had uniformly diſtinguiſhed it from the firſt days of ſir Robert Walpole. In the year 1784, however, when Mr. Pitt, after having been forced to reſign with lord Shelburne in the preceding year, was raiſed to the chief adminiſtration of public affairs, the ruinous plans which had hitherto been purſued were diſcontinued, and very conſiderable improvements were made both in the mode of conducting the loans which were neceſſary for diſcharging the arrears of the late war, and in the general arrangement of the public accounts. Inſtead of borrowing at a low intereſt, and thus adding a needleſs capital to the public debt, the meaſure ſo often recommended by Dr. Price, of borrowing at a high intereſt, with the view of facilitating the redemption of the debt, was adopted, and the public accounts were thrown into new order, by aboliſhing the former diviſion of the taxes under the four heads of *Aggregate, South-ſea, General*, and *Sinking funds*, and including the whole in one fund called the *Conſolidated fund*. The ſurplus remaining, after deducting from the taxes thus conſolidated, all the expences of the public debts and the civil liſt, correſponded with what was formerly called the *Sinking fund*. This ſurplus, which Mr. Pitt eſtimated at a million annually, though it never fairly produced half that ſum during the whole time that intervened between the eſtabliſhment of the fund and the commencement of the French war, was appointed by parliament to be applied to the gradual diſcharge of the public debt. For this important meaſure the miniſter was wholly indebted not only to the writings but to the immediate advice and aſſiſtance of Dr. Price. But in claiming the honour of having his name inſcribed on a pillar to public credit for having adopted it, Mr. Pitt thought proper to aſſume the whole merit of the meaſure to himſelf, without the ſlighteſt notice of the ſource from which he had derived his information, and thus exhibited a much leſs equivocal proof of his ambition than either of his magnanimity or gratitude.

Of the three plans which Dr. Price communicated at his requeſt, Mr. Pitt choſe the moſt feeble, from the fear of adding to the taxes 600,000*l.* a year, which would have been required to aſſiſt the operations of the other plans. Happy had it been for the nation if he had always entertained the ſame apprehenſions, however much it may be regretted that he ſhould have been influenced by them on this occaſion.

In the firſt plan, it was propoſed by Dr. Price, in addition to the million ſurplus, to aid the operations of the fund by the falling in of the temporary and life annuities, by converting 60 millions of three per cents into four per cents, and providing in the firſt five years 600,000*l.* per annum, for paying the difference of intereſt. In the courſe of 30 years this would have redeemed 114,491,991*l.* of ſtock in the three, four, and five per cents, and given a free revenue of 6,345,566*l.* In the ſecond plan, all the ſame aids were propoſed, except that the converſion of the three per cents into four per cents was omitted. This would have retarded the operations of the fund in a ſmall degree, as the ſtock redeemed in the three, four, and five per cents, in the courſe of 30 years, would have amounted only to 101,721,266*l.*, and the free revenue would have been only 6,069,709*l.* In the third, which in fact is the plan adopted by Mr. Pitt, no other aid was propoſed to the million ſurplus than the temporary and life-annuities as they fell in, and ſuppoſing the ſtock to have been redeemed in the three, four, and five per cents, in the manner directed by Dr. Price, it would have amounted, in 30 years only, to 73,379,126*l.* and the free revenue to 4,579,731*l.*, or to little more than two-thirds its amount by the firſt plan. Since the eſtabliſhment of this plan, it has been the cuſtom of parliament to vote annually the ſum of 200,000*l.* in addition to the million ſurplus, by which its operations have been ſo far accelerated. But on the other hand they have been retarded, for the purpoſe of aſſiſting the public loans, by the partial, and at laſt the total alienation of the 30 years annuity, amounting to 418,333*l.* per annum.

When the ſinking fund was eſtabliſhed in the year 1786, the public debt, excluſive of the temporary annuities, conſiſted of

187,611,254*l.* in the three per cents,
32,750,000*l.* in the four per cents,
17,869,994*l.* in the five per cents;

amounting in the whole to 238,231,241*l.* By the operation of Dr. Price's plan, which was founded on a ſyſtem of peace, and conſequently on the ſuppoſition that in the courſe of a very few years the four per cents would have riſen to par, the whole of that ſtock and of the five per cents, together with 4,074,574*l.* ſtock in the three per cents, would have been redeemed at the preſent time, leaving a free revenue of 3,892,831*l.* and reducing the permanent debt to 183,536,680*l.* ſtock in the three per cents, which would have required little more than five millions and a half annually to pay the intereſt of it. Nor have the operations of this plan diſappointed the hopes and expectations of the public. They have in fact exceeded the computations of Dr. Price; but this has ariſen from a cauſe by no means favourable either to the credit or the welfare of the country. By a ruinous war, in which the nation has been almoſt inceſſantly involved during the laſt 18 years, and which, by increaſing the debt twenty times faſter than it could poſſibly be reduced, has at different times depreciated the funds ſo low, that the ſums appropriated for the redemption of the debt have purchaſed nearly twice as much ſtock as they would otherwiſe have done. From the manner, however, in which the accounts are laid before parliament, it is impoſſible to aſcertain the exact amount of the debt which has been redeemed by the ſinking fund, as it was firſt eſtabliſhed in 1786; for its operations are blended with thoſe of another fund which was eſtabliſhed ſoon after, for the purpoſe of redeeming any new debt which ſhould be incurred by the public.

In the ſeveral tracts which Dr. Price had written on the ſubject, he had ſtrongly inſiſted on the neceſſity, not only of redeeming the preſent, but alſo of diſcharging any future debt, by providing a ſpecial fund for that purpoſe, and with that view he recommended that 1*l.* on every 100*l.* borrowed ſhould be annually applied to the redemption of the capital, (which it would accompliſh in leſs than 40 years,) that by this means the debt might be prevented from becoming a perpetual burden on the country. In conformity with this recommendation of Dr. Price an act of parliament was paſſed, which directed, that in all future loans an additional ſum of 1*l.* per cent over and above the annual intereſt ſhould be raiſed by taxes towards redeeming the principal, and ſo enormous has been the expenditure ſince the paſſing of that act, that this additional ſum amounted, in February laſt (1810) to 3,841,567*l.* excluſive of 56,445,000*l.* which had been borrowed during Mr. Pitt's adminiſtration, on the ſecurity of the income-tax, and which has ſince been funded without any ſpecial proviſion for its redemption. With this ſum, and the accumulating dividends on the ſtock purchaſed with it, together with the ſurplus million, the annual ſum of 200,000*l.* voted by parliament, the dividends on the ſtock purchaſed with both, and about 91,000*l.* per ann. gained by the falling in of ſome life annuities, the commiſſioners had in February the ſum of 10,509,392*l.* as annually

nually applicable to the reduction of the debt of Great Britain, and the whole of what they had then redeemed amounted to

149,271,236*l.* ſtock in the three per cents,
6,629,700*l.* ſtock in the four per cents,
142,000*l.* ſtock in the five per cents, or 156,042,936*l.*

But in order to ſhew what progreſs has really been made in reducing the public debt by the financial operations of miniſters, it will be neceſſary to obſerve that the whole maſs, excluſive of the debt incurred in the preſent year and of the addition to the temporary annuities, amounted in February to

596,156,564*l.* ſtock in the three per cents,
66,076,985*l.* ſtock in the four per cents,
60,213,221*l.* ſtock in the five per cents, or 722,446,770*l.*

Deducting from this ſum 156,042,936*l.* purchaſed by the commiſſioners, there will remain unredeemed of the perpetual annuities 566,403,834*l.*; and as the purchaſes have almoſt wholly been made in the three per cents, a very conſiderable part of this debt conſiſts of four and five per cents, which makes the real amount of it, when compared with the debt in 1786, nearly four times greater than what it would have been, had no wars intervened to diſturb the operations of the ſinking fund.

In the courſe of the laſt five years about 140 millions have been added to the capital of the public debt, which, requiring an annual addition of ſix millions nearly to the permanent taxes, recourſe has been had, among a variety of other expedients for preventing the neceſſity of impoſing new burthens, to the perpetuating a part of the war-taxes which were meant only to be temporary, and to the alienation of the annuities that expired in 1808, which were originally to have been applied in aid of the ſinking fund. By theſe means, in conjunction with the meaſure of funding above 56 millions of three per cents, without any proviſion for their redemption; the country, ſhould the preſent deſolating war be ever ſucceeded by an interval of peace, will neither be relieved immediately from the extraordinary weight of its new burthens, nor, as it ought to have been, from the length of time in which it is to bear its old ones.

In a former period, when the miniſter began to encroach on the ſinking fund under pretence of relieving the public, he never ceaſed to repeat his encroachments with increaſing violence till he had entirely deſtroyed it. In the preſent period we have witneſſed ſimilar encroachments from ſimilar motives; and if the public expenditure ſhould proceed in the courſe which has diſtinguiſhed this war above all others for a few years longer, it is not improbable that the ſame ſpecious pretence will be urged for repeating thoſe encroachments; until at length the whole fund is alienated, and the laſt hope of the country to be ever relieved from its burthens is totally extinguiſhed.

FUND *for the Support of decayed Muſicians and their Families.* This fund, the firſt of the kind, has been the model of ſimilar eſtabliſhments abroad and at home. On the continent it has been imitated at Vienna, Gottingen, Leipſic, and Hamburg; and at home, in our theatres. Mr. Garrick, when he had quitted the ſtage, and only acted occaſionally, eſtabliſhed a fund for the ſupport of decayed actors and actreſſes; and continued to perform a capital part for its benefit, annually, to nearly the laſt year of his life. For this benefit he wrote, and ſpoke, the moſt humorous prologue, in a mock-heroic ſtyle, which his fertile pen in addreſſes to an audience ever produced. The ſame laudable kind of fund for decayed and worn out actors and their families has been eſtabliſhed at Covent Garden.

The original fund for decayed muſicians had its beginning in 1738, on a ſmall ſcale, by opening a ſubſcription among muſical profeſſors, of only half-a-crown a quarter; forming themſelves into a ſociety, electing 12 governors, to be renewed annually, and agreeing to 14 reſolutions, which are all inſerted in the appendix to the account of the Commemoration of Handel, publiſhed in 1785, 4to.

In 1739, a compact was formed with the corporation of "the Sons of the Clergy," by which the ſociety engaged to furniſh a band, ſelected from their ſubſcribing members, for the two annual performances at St. Paul's cathedral, in conſideration of the ſum of fifty pounds, which the corporation agreed to allow each year to the muſical ſociety; and this ſum has been conſtantly thrown into the fund, and appropriated to charitable purpoſes.

Beſides the caſual and fluctuating income ariſing from ſubſcriptions and benefits, the ſociety has been honoured with a few benefactions in the way of legacies, of which the following is an account:

In 1738, 100*l.* by Mr. Rojere, one of its profeſſional members.

In 1760, 50*l.* by Mr. Waldron, do.

In 1782, 50*l.* by Mr. James Mathias, an honorary ſubſcriber, with an excellent baſs voice; whoſe performance as a dilettanti at the Crown and Anchor concerts was long admired.

But the moſt conſiderable legacy which the ſociety ever received was from the admirable and benevolent Mr. Handel; who bequeathed to the eſtabliſhment 1000*l.*

From the performances at the commemoration of this great and illuſtrious muſician, whoſe works had been the chief attractions at their annual benefits, the fund received an addition to their capital from the noblemen and baronets who planned and directed this extraordinary celebration, 6000*l.*

At their annual benefits, the principal profeſſional ſubſcribers to the charity, who are not employed in the orcheſtra, are appointed to attend at the ſeveral doors and offices of the theatre; the whole buſineſs being tranſacted by themſelves, as ordered and regulated by a committee for the concert, or whatever the perfomance may be; and it ſeems as if no charitable inſtitution could be more out of the reach of abuſe, embezzlement, or partiality; regulated with more care, integrity, and economy; or have its income ſo immediately derived from the activity and talents of its own members.

Except a ſmall ſalary to the ſecretary, and another to the collector, there is no lucrative employment belonging to the inſtitution: ſo that the whole produce of benefits and ſubſcriptions is nett, and clear of all deduction or drawback.

Though the firſt ſubſcription from profeſſional members was only half-a-crown a quarter, in 1766 the ſum of 20 ſhillings per annum was required of all new members, inſtead of ten. And the old members then agreed, almoſt unanimouſly, to pay the ſame ſum. Since that period, the annual demand on the profeſſional ſubſcribers has been ſettled at one pound two ſhillings, and the benefit tickets have the ſame price as at the Commemoration; that is to ſay, a guinea each, ſo that the ſubſcription of honorary members has been doubled.

Mr. Michael Chriſtian Feſting, and doctor Maurice Green, took the lead at the time of inſtituting this ſociety, and for twelve or fourteen years afterwards. Since their deceaſe, other muſicians, who were high in the profeſſion, and of whoſe probity and honour their brethren had a good opinion, were placed alternately in the chair, and now, by the

the great acceſſion to the fund from the profits of the ever memorable Commemoration, its capital becomes a ſerious and weighty concern, amounting to upwards of 22,000 *l.* in South-ſea annuities and three per cents, which realizes and aſcertains an income of 678 *l.* a year, excluſive of benefits or ſubſcriptions.

The path therefore which the governors and court of aſſiſtants have now to purſue is perfectly plain and pleaſant. The power of alleviating diſtreſs and miſery, of feeding the hungry, cloathing the naked, and adminiſtering comfort to age and infirmities, is placed in their hands without the trouble of providing the means.

FUNDAMENT, the anus or aperture through which an animal voids his excrements.

FUNDAMENTAL, ſomething that ſerves as a baſe, reſt, ſupport, or foundation, for any thing.

The apoſtles creed contains the fundamental points of religion. The Salic law is the fundamental law of the polity of France.

FUNDAMENTAL, in *Muſic*, denotes the principal note of a ſong or compoſition, to which all the reſt are in ſome meaſure adapted, and by which they are ſwayed; called alſo the *key* of the ſong.

FUNDAMENTAL *Baſs*. See BASSE *Fondamentale*, and FONDAMENTALE.

FUNDAMENTAL *Concords* are of three kinds; *viz.* the perfect concord, the concord of the ſixth, and the concord of the ſeventh. The firſt or perfect concord is greater or leſs, according as the third is greater or leſs. The ſecond is of three ſorts: in the two firſt ſorts the ſixth is always greater, and the third greater or leſs, as the mode is greater or leſs. Theſe two concords differ only by their third. Between theſe two there is another concord, which on many occaſions produces a very good effect, and is particularly uſed by the Italians; whence it is called the concord of the ſuperfluous ſixth, or of the Italian ſixth. It is compoſed of a greater third, or ſuperfluous fourth, or tritone, and a greater third, as *fa la ſi rè* ※. There are ſeveral kinds of the fundamental ſeventh: the firſt is formed of a greater third, and two leſſer thirds, as *ſol ſi rè fa*; the ſecond is formed of a leſſer third, a greater third, and a leſſer third, as *re fa la ut*; the third is formed of two leſſer thirds, and a greater third, as *ſi rè fa la*; the fourth is formed of one greater third, one leſſer, and one greater, as *ut mi ſol ſi*; the fifth is called the concord of the diminiſhed ſeventh, and formed of three leſſer thirds, *ſo* ※ *ſi rè fa*. See CONCORD.

FUNDAMENTAL *Rock*, in *Geology*, (or baſis,) is a term uſed by Mr. Kirwan, and by many of the German geologiſts, for the baſis or ſolid nucleus of the earth, on which the ſuperficial ſtrata have been depoſited. This fundamental rock is ſaid to be granite, but we much doubt the truth of this poſition, except ſo far as it may abound in the lower part of the ſeries of ſtrata viſible on the ſurface; becauſe an immenſe maſs of matter, much heavier than granite, is neceſſary, in the central parts of the earth, to account for the ſpecific gravity (4.4 to 5.4) which modern and concurrent experiments have ſhewn to belong to the terraqueous globe. See EARTH and GRAVITY.

FUNDAMENTO, in the *Italian Muſic*, is in general every part that plays or ſings the baſs; but the thorough-baſs is more particularly ſo called, becauſe it is the baſis or foundation of all harmony.

FUNDAON, in *Geography*, a town of Portugal, in the province of Beira; 22 miles W. of Alfayates.

FUNDI. See FONDI.

FUNDO, a town of European Turkey, in Moldavia; 44 miles W.N.W. of Birlat.

FUNDUCLÆ, an Ægyptian coin, a ſort of ſequin, of the value of a hundred and forty-ſix medines. Pococke's Egypt, p. 175.

FUNDULUS, in *Zoology*, a name uſed by many for the ſmall fiſh, called by others *cobitis barbatula*, and by the generality of people in England the *loach*.

FUNDULUS is uſed alſo by Schoneveldt, and ſome others, to expreſs the common gudgeon, or CYPRINUS *gobio*.

FUNDY, in *Geography*, a large bay in North America, which opens between the iſlands in Penobſcot bay, in the county of Lincoln and ſtate of Maine, and Cape Sable, the ſouth-weſtern point of Nova Scotia. It extends about 200 miles in a N.E. direction; and with Verte bay, which projects into the land in a S.W. direction from the ſtraits of Northumberland, forms a very narrow iſthmus, uniting Nova-Scotia to the continent, where the diviſion line runs between that province and New Brunſwick. From its mouth up to Paſſamaquoddy bay, on its N.W. ſide, ſituated between the province of New Brunſwick and the diſtrict of Maine, are a number of bays and iſlands on both ſides, and thus far it contracts its breadth gradually. It is 12 leagues acroſs from St. John's in New Brunſwick to the gut of Annapolis, in Nova Scotia, where the tides are rapid, and riſe 30 feet. Above this it preſerves nearly an equal breadth, until its waters are formed into two arms by a peninſula, the weſtern point of which is called Cape Chigneeto. At the head of the north-eaſtern arm, called Chigneeto channel, which forms with bay Verte the iſthmus, the tides riſe 40 feet. Theſe tides are ſo rapid as to overtake animals feeding on the ſhore.

FUNEN, or FYEN, an iſland of Denmark, at the entrance of the Baltic, nearly of an oval form, extending from N. to S. about 35 miles, and from E. to W. about 30; it is a fertile and pleaſant iſland, in which many of the Daniſh nobility have ſeats. The ſoil yields great crops of corn, ſo that nearly 10,000 barrels are exported annually to Norway and Sweden, excluſively of the home-conſumption. The inhabitants keep large ſtocks of bees, and with the honey they make mead, which forms a conſiderable article of trade. In this iſland are ſeveral lakes and rivers abounding in fiſh, but none of them are navigable: great quantities of cod, herring, turbot, and other fiſh are caught in the bays along the coaſt. The capital is Odenſee. N. lat. 55° 7′ to 55° 36′. E. long. 9° 40′ to 10° 50′.

FUNERAL, the ceremonies performed at an interment; or the laſt offices paid to the deceaſed. See BURIAL.

The word is formed of the Latin *funus*; and that of *funalia*, on account of the torches (which were *funes, cera circumdati*) uſed in the funerals of the Romans; though others derive *funus* from the Greek φονος, *death* or *ſlaughter*.

The firſt perſons who ſeem to have paid any particular reſpect to their dead were the Egyptians, who erected monuments for tranſmitting the remembrance of their virtues to future ages. See PYRAMID.

Whenever a perſon died among the Egyptians, his parents and friends put on mournful habits, and abſtained from all banquets and entertainments. This mourning laſted from forty to ſeventy days, during which time they embalmed the body. See EMBALMING.

When this ceremony was finiſhed, the embalmed body was reſtored to the parents, who placed it in a kind of open cheſt, which was preſerved either in their houſes, or in the ſepulchres of their anceſtors. Before the dead were allowed to be depoſited in the tomb, they underwent a ſolemn judgment, which extended even to their kings; and if the iſſue of the judgment proved unfavourable, they were deprived of the rights of burial; and this cuſtom ſeems

to have been practiſed among the Iſraelites; for we read that their wicked kings were not interred in the ſepulchres of their anceſtors.

The funeral rites among the ancient Romans were very numerous. The deceaſed was kept ſeven days; and every day waſhed with hot water, and ſometimes with oil, that, in caſe he were only in a ſlumber, he might be thus waked; and every now and then his friends meeting, made a horrible outcry or ſhout, with the ſame view; which laſt action they called *conclamatio*.

The third conclamation was on the ſeventh day; when, if no ſigns of life appeared, the defunct was dreſſed and embalmed by the pollinctories: placed in a bed near the door, with his face and heels towards the ſtreet; and the outſide of the gate, if the deceaſed were of condition, was garniſhed with cypreſs boughs.

In the courſe of theſe ſeven days an altar was raiſed near his bed-ſide, called *acerra*; on which his friends every day offered incenſe; and the libitinarii provided things for the funeral.

On the ſeventh day a crier was ſent about the city to invite the people to the ſolemnization of the funeral in theſe words: "Exequias L. Tit. L. filii, quibus eſt commodum ire, jam tempus eſt. Ollus (i. e. ille) ex ædibus effertur."

The people being aſſembled, the laſt conclamation ended, and the bed was covered with purple; a trumpeter marched forth, followed by old women, called *præficæ*, ſinging ſongs in praiſe of the deceaſed; and laſtly, the bed followed, borne by the next relations. And if the perſon were of quality and office, the waxen images of all his predeceſſors were carried before him on poles.

The bed was followed by his children, kindred, &c. *atrati*, or in mourning: from which act of following the corpſe, theſe funeral rites were called *exequiæ*.

The body thus brought to the roſtra, the next of kin *laudabat defunctum pro roſtris*, made a funeral oration in his praiſe, and that of his anceſtors.

This done, the body was carried to the *pyra*, or funeral pile, and there burnt: his friends firſt cutting off a finger, to be buried with a ſecond ſolemnity.

The body conſumed, the aſhes were gathered: and the prieſt ſprinkling the company thrice with clean water, the eldeſt of the *præficæ* crying aloud, *ilicet*, diſmiſſed the people, who took their leave of the deceaſed in this form, "Vale, vale, vale: nos te ordine quo natura premiſerit, ſequemur."

The aſhes, incloſed in an urn, were laid in the ſepulchre, or tomb. The firſt Romans did not burn their dead, but interred them as we do. Pliny, lib. vii. cap. 54. aſſures us, that the cuſtom of burning was not introduced till after they had learnt that their enemies dug up, and expoſed, the bodies of their ſoldiers buried in remote countries. And yet Plutarch, in his life of Numa, obſerves that Numa was buried; as having expreſsly forbade them, by his teſtament, to burn: this ſhews that the Romans had practiſed burning before his time.

This cuſtom of burning the dead, ſo religiouſly obſerved by the Greeks and Romans, was held in abhorrence by ſeveral other nations.

Herodotus relates, that the Perſians deteſted it, as holding fire to be a god. The Egyptians declined to burn their dead, as taking fire for an inanimate beaſt, and judging it impiety to commit the bodies of the deceaſed to be devoured by beaſts. The cuſtom of burning among the Romans ceaſed under the empire of the Antonines. See BURNING and MOURNING.

In the Romiſh church, when a perſon is dead, they waſh the body, and put a crucifix in its hand. At its feet ſtands a veſſel of holy water, that they who come in may ſprinkle both themſelves and the deceaſed. In the mean time ſome prieſt ſtands by the corpſe, and prays for the deceaſed till it is laid in the earth. In the funeral proceſſion the exorciſt walks firſt, carrying the holy water, next the croſs-bearer, afterwards the reſt of the clergy, and laſt of all the officiating prieſt. They ſing the *miſerere*, and ſome of the Pſalms; and at the end of each Pſalm, a *requiem*. We learn from Alet's ritual, that the faces of deceaſed laymen muſt be turned towards the altar when they are placed in the church; and thoſe of the clergy towards the people. The corpſe is placed in the church, ſurrounded with lighted tapers; after the office for the dead maſs is ſaid; then the officiating prieſt ſprinkles the corpſe thrice with holy water, and as often throws incenſe on it. The body being laid in the grave, the friends and relations ſprinkle the grave with holy water.

FUNERAL *Charges* are not allowable againſt a creditor, except for the coffin, ringing the bell, parſon, clerk, and bearers fees, but not for the pall and ornaments. See DEBT and EXECUTOR.

FUNERAL *Column*. See *Funeral* COLUMN.

FUNERAL *Games*, *ludi funebres*, were a part of the ceremony of the ancient funerals.

They conſiſted chiefly in proceſſions, and ſometimes in mortal combats of gladiators around the funeral pile.

The cuſtom was very ancient, though it had not always been the ſame. At firſt they cut the throats of a number of captives before the pyra, as victims to appeaſe the manes of the deceaſed. This Achilles does in Homer, Iliad ϕ, at the funeral of Patroclus; and Æneas, in Virgil, lib. ix. at that of Pallas, ſon of Evander. Cæſar, in his Commentaries, lib. viii. relates, that the Gauls alſo did the like.

But at length it appeared barbarous thus to butcher man; and therefore to ſave the horror of the ſpectacle, yet without the dead's loſing any thing thereby, they made the poor captives fight and kill one another, only ſaving ſome few of ſuch as came off victors.

This cuſtom was borrowed from the Greeks by the Romans; among whom the cruel diverſion was called *munus*.

The firſt who introduced it at Rome was Junius Brutus, at the obſequies of his father; or, according to others, Ap. Claudius, and M. Fulvius, during their conſulate.

The like horrible combats were alſo occaſionally exhibited by the magiſtrates; and ſometimes they were added to the theatrical pieces.

The emperor Claudius decreed, that whereas theſe accurſed games were till then frequent and arbitrary; it ſhould be the practice, for the future, only to perform them regularly every year at the expence of the ſtate; and that the ædiles ſhould have the care and direction thereof. But he conceived a horror for them himſelf, and ſoon after aboliſhed them; though it was ſtill allowed particular perſons to have them, provided they were worth forty thouſand ſeſterces per annum. They were not finally aboliſhed before the time of Theodoric king of the Goths, at the end of the fifth century.

FUNERAL *Honours*. See HONOURS.

FUNERAL, *Military*, is uſually attended with many ſolemnities, ſuch as cannot fail to prove deeply impreſſive on the minds of the ſpectators, and to evince the reſpect in which the deceaſed was held. The funeral of an officer high in rank generally forms an extenſive proceſſion of horſe and foot;

ſoot; on ſuch occaſions the garriſons, or detachments they commanded, parade, and a portion, deſignated the "funeral party," precede the corpſe in open order, with their arms reverſed, the drums muffled, and the band playing the dead march, or ſome ſolemn airs, ſuited to the occaſion. The officers, in lieu of leading, follow their ſeveral diviſions; all wearing crapes both on the left arm and on their ſwords: the ſenior corps and the ſenior officers being reſpectively neareſt the corpſe. The pall is ſupported by officers of equal, or of ſuperior rank to the deceaſed, whoſe ſword and ſaſh are laid on the lid of the coffin. In many inſtances the union colours of the regiment are borne as a pall, being previouſly diſengaged from the ſtaff. The chief mourners, among whom are commonly the officer on whom the command devolves, together with the ſtaff of the deceaſed, and of the ſtation, &c. follow the corpſe, and the whole uſually paſs through a lane formed by the ſeveral regiments wearing their ſide arms, which, as ſoon as they have proceeded, cloſe and follow in order. On arriving near the place of interment, the lane is again formed, and the funeral party open to the right and left, reſting on their arms reverſed in a ſorrowful poſition. The corpſe and mourners having moved beyond them, they again form and follow to the grave, near which, during the ſervice, they remain at ordered, or reverſed, arms, and conclude the ceremony by firing three vollies over the corpſe, as the earth is filling over it. During the whole time the colours of the fortreſs are lowered to half-maſt high, and minute guns are fired, correſponding in number with the years of the deceaſed.

To officers of inferior rank proportionate honours are paid; thoſe who commanded regiments being fired over by their flank companies, and attended by the reſidue as mourners. Captains are uſually attended by their own companies as funeral parties, and by a proportion of others as mourners: ſubalterns by ſmall parties to fire over, and the reſidue of the company as mourners. Even a private ſoldier has a funeral party of a ſerjeant, a corporal, and twelve men; and if his conduct while living gave ſatisfaction, moſt of the company will be ſeen to attend. On ſome occaſions, non-commiſſioned officers and privates have been ſo highly eſteemed as occaſion their mournful followers to be very numerous.

Naval funerals depend much on circumſtances: where they take place in any friendly port, the corpſe is generally ſent aſhore to be interred according to the forms above deſcribed, the marines furniſhing the funeral party, and a ſuitable number of officers attending to bear the pall, together with ſeamen to bear the coffin, and to follow as mourners. When an officer of high rank is to be interred, the enſign of the ſhip, and the flag of the deceaſed, are lowered half way down their reſpective ſtaves; the barge conveying the corpſe is hung with black, and the rowers wear crapes, &c. The band, which in theſe, as well as in military funerals, has its inſtruments furniſhed with black ribbon, the drums being muffled and covered with black crape, perform ſolemn muſic. All the ſhips in port lower their colours to half maſt, and the ſhip from which the corpſe proceeds to the ſhore, in particular, fires minute guns.

At ſea, and in an enemy's harbour, ſuch a mode of interment cannot take place, therefore the body, if not preſerved for the purpoſe of being buried aſhore, muſt be ſewed up in a hammock, which may again be caſed either in black woollen, &c. or in a wooden ſhell; being duly laden with ſhot, or any ponderous ſubſtance, it is laid upon a grating taken from one of the hatchways, and laid upon the lee-gunnel. There the uſual ſervice is performed by the chaplain, or, for want of one, by ſome officer, and the corpſe is launched into the deep. It is ſometimes the practice to fit out the ſhip's barge, or her long-boat, &c. on ſuch occaſions, and to cauſe the body to be rowed from ſhip to ſhip, receiving from each ſome token of reſpect, ſuch as manning the rigging in ſilence, lowering the colours to half maſt, performing ſolemn muſic, and occaſionally by firing a certain number of guns. The ſervice is concluded in the boat bearing the corpſe, which is then conſigned to the deep.

It is not eaſy to deſcribe the decorum which prevails on theſe occaſions, nor to give an adequate idea of the impreſſion made on a very large portion of any crew loſing an agreeable companion. His conſignment to "Davy Jones's Locker," as it is technically called, produces much affliction among thoſe who were his immediate meſſmates, who eye his ſpoon, which often becomes a ſacred relic, as it remains unuſed in the common bracket, with far more emotion than, from a ſuperficial acquaintance with the naval character, one ſhould expect to witneſs. The abſence of a fellow-ſeaman, who, according to the common phraſe, has "ſtuck up his ſpoon," cannot be unnoticed; every thing calls the loſt aſſociate back to the memory, in which his good qualities are ſure to be indelibly recorded!

FUNERAL *Oration*, or *Sermon*, a diſcourſe pronounced in praiſe of a perſon deceaſed, at the ceremony of his funeral.

The cuſtom of making funeral orations is very ancient. The Romans had it of a long ſtanding; and it was always one of the neareſt relations that made the harangue. Auguſtus did the office to his grandmother Julia, when only twelve years of age. Suet. Aug. cap. 8. And we have divers parallel inſtances.

The cuſtom ſeems to have begun with the republic; at leaſt, the firſt funeral oration we read of was that of Brutus, who expelled the kings, and was the firſt conſul; who having been killed in a battle againſt the Etrurians, *laudabatur pro roſtris*, was praiſed in the forum by Valerius Publicola his colleague.

Indeed, ſome authors will have the practice more ancient. They maintain it to have been in uſe among the Greeks; and that Solon, who, according to Aulus Gellius, gave laws to the Athenians, in the time when the elder Tarquin reigned in Rome, was the firſt author thereof; ſomething like which, it ſeems, the orator Anaximenes has left in writing. See Polydore Virgil De Invent. Rer. lib. iii. cap. 10. See DEMONSTRATIVE.

FUNES, in *Geography*, a town of South America, in the province of Popayan; 15 miles S. of Paſto.

FUNFKIRCEN, or *Five Churches*, a town of Hungary, ſituated in a fertile ſoil between the Drave and the Danube, the ſee of a biſhop. An univerſity was founded in this place by Louis I., and it had at one time 2000 ſtudents; but when the Turks obtained poſſeſſion of the town, the univerſity declined, and it has never ſince recovered. The number of its inhabitants is about 12,000; 110 miles W. of Belgrade. N. lat. 46° 6′. E. long. 18 9′.

FUNGENO, or FUNGANDO, a kingdom of Africa, ſituated between the Zaire and the Coanza, ſubject to Anziko.

FUNGI, in *Botany*, a Natural Order of Plants, the fourth of the claſs *Cryptogamia*, as originally eſtabliſhed by Linnæus, is reckoned among the *Acotyledones* by Juſſieu. This order includes all thoſe productions commonly known by the name of Muſhrooms, as well as a numerous tribe of ſimilar vegetable bodies, differing in firmneſs from a watery pulp of very ſhort duration, to a leathery or even woody texture, often very permanent. They cannot properly be ſaid to have any herbage, much leſs any thing like leaves or flowers in appearance, however their different parts may perform

perform functions analogous to what are proper to ſuch organs. Acharius, like many of his predeceſſors, reckons them deſtitute of ſexual organs, or any thing analogous to *ſtamina* and *piſtilla*; but this opinion is altogether theoretical, like the aſſertion of Juſſieu, which denies them cotyledons. Neither has been proved, nor is either of any practical uſe, for the purpoſes of ſyſtematical arrangement. Some have thought *Fungi* to be of an animal nature, becauſe of their fœtid ſcent in decay, and becauſe they are occaſionally the habitations of inſects, which were ſuppoſed to form them as polypes do corals, an idea ſcarce worthy of refutation. The ſuppoſition maintained by ſome, of their originating from the tranſmuted ſap of corrupted wood, is equally futile. They are in fact as diſtinct in genus and ſpecies as any other vegetables, and propagate themſelves as regularly, though, like other plants, ſubject to varieties.

Dryander, Schæffer, and Hedwig, have aſſerted their vegetable nature, and in many inſtances demonſtrated their ſeeds; in ſome caſes their organs of impregnation have been, with great probability, pointed out.

The chief writers on *Fungi* are Schæffer, Batarra, Bulliard, Sowerby, Schrader, Tode, and Perſoon, the latter being the beſt ſyſtematic author in this department. He divides them into two principal ſections. 1. *Angiocarpi*, bearing their ſeeds internally, like the *Lycoperdon*, or Puffball; and 2. *Gymnocarpi*, whoſe ſeeds are imbedded in an appropriate, dilated, expoſed membrane, called *hymenium*, of which the common eatable muſhroom, *Agaricus pratenſis*, is an example. In this genus, *Agaricus*, the *hymenium* conſiſts of parallel plates, termed gills.

Fungi *eſculenti*. See Phallus.

FUNGIFER Lapis, the *muſhroom-bearing ſtone*, a name given by authors to a coarſe ſtone found in Italy, and many other places, lying near the ſurface of the earth, which they ſay will at any time produce muſhrooms, on being moiſtened with warm water.

FUNGITÆ, in *Natural Hiſtory*, a name given by authors to a ſpecies of ſea-coral, often found adhering to ſea-ſhells, or to the larger corals in its recent ſtate, and very often found alſo foſſile, or buried at great depths in the earth; they are uſually immerged in ſtone, and ſometimes in clay. The more frequent of theſe are of a conic ſhape; ſometimes they are flatted and diſcoid, and uſually ſtriated longitudinally; they ſometimes are found in their foſſil ſtate adhering to ſhells or corals, but more uſually ſeparate. To this, and ſome other bodies of this kind, Mr. Lloyd has given the name *columella*; to one of them, that of *branchiale*, from its reſembling the gills of a fiſh; and to another, that of *undulago*, from its undulated figure. Mr. William Martin, (Outlines, &c. p. 83.) a late writer, who ſeems to have ſtudied the ſubject of extraneous foſſils or reliquia, as he calls them, with the beſt effect, conſiders the exiſtence of petrified fungi as extremely doubtful, and refers ſuch ſpecimens as he has examined to the claſs of coralline bodies, to which they ſeem evidently to belong.

FUNGITES, a ſpecies of *Madrepora*; which ſee.

FUNGOIDASTER. See Hevella.

FUNGOIDES. See Agaricus, Clavaria, Helvella, and Peziza.

FUNGOUS Flesh, is a ſpongeous excreſcence, or (as we popularly call it) *proud fleſh*, frequently growing on the lips of wounds, ulcers, &c. See Fungus.

Fungous *Tumours*. See Tumours.

FUNGUS, in *Mineralogy*, a name given by Dr. Liſter to a blackiſh bituminous ſubſtance, found in ſome of the mines of Derbyſhire. It adheres to the ſides of the fiſſures of rocks, and lies in ſeams of the ſtrata. It is of a blackiſh colour, and fatty ſubſtance, which never dries in the air, but always remains as moiſt as when taken out of the mine. Some maſſes of it are ſoft and like a jelly, others are hard and firm, and in theſe there are ſeveral lumps of pure bitumen in many parts. This is inflammable like reſin. It is light, but breaks finer, and ſhines like good aloes when freſh broken, but that it is a little darker coloured, and has ſome tinge of purple in it. In ſome pieces the purple is wanting, and there is a green in the place of it. On being diſtilled, it yields firſt a limpid and inſipid water, then a whitiſh water of a ſharp taſte, and finally a yellow and clear oil, much reſembling oil of amber, but the proceſs affords no volatile ſalt in the neck of the receiver, in which it differs from amber when treated in the ſame manner. Phil. Tranſ. N° 6.

Fungus, in *Natural Hiſtory*. See Fungi, Madrepora, and Mushroom.

Fungus, in *Surgery*, ſignifies a ſpongy excreſcence, which is generally compoſed of large, high, flabby, ſometimes firm, granulations, and is apt to bleed from ſlight cauſes, being attended with various degrees of pain in different caſes and under different circumſtances. As the diſeaſe conſiſts of an organized, vaſcular ſubſtance, it is commonly its nature to continue to become larger and larger, unleſs its growth be ſtopped by ſome deciſive method of treatment on the part of the ſurgeon. It is almoſt impoſſible for us to give the reader an adequate idea of the miſery and dreadful ſufferings which certain fungous diſeaſes bring upon mankind. Some of theſe excreſcences, it is true, are only attended with ſlight inconvenience and occaſional pain; but many others, beſides being at all times horridly painful, reduce the unhappy patient to the extreme ſtate of debility, partly by producing repeated hemorrhages, and partly by occaſioning loſs of reſt, fever, &c. Some fungous diſeaſes aſſume a malignant character, becoming cancerous, or, (if poſſible) worſe than a cancer, ſo that ſhould they be too extenſive for extirpation, the conſequences muſt be fatal.

In the article Dura Mater, *Tumours of*, we have deſcribed one ſpecies of fungus which grows from the dura mater, makes its way outward by producing an abſorption of the tables of the ſkull, lifts up the ſcalp, and, at length, ulcerates the ſkin ſo as to protrude at ſome part of the head, quite free from every kind of covering. Such ſwellings have ſometimes been ſucceſsfully deſtroyed; but, too frequently, they affect the brain underneath and prove fatal. The reader, however, is referred for an account of this ſubject to the above-mentioned article.

A milder and leſs alarming form of fungus is ſeen in ſuch excreſcences as the ficus, condyloma, &c. which frequently occur about the anus, perinæum, and pudenda. The manner of curing theſe diſeaſes we have deſcribed under the head of Excrescence.

Fungous excreſcences are not confined to any particular parts or ſtructures; they may originate in almoſt any ſituation in the body. However, there are certain circumſtances which are particularly often attended with the appearance of a fungus. When a ſurgeon, in removing an encyſted tumour, leaves a portion of the cyſt behind, a fungus is very apt to grow from the ſurface of this latter part, and prove a great deal more troubleſome than the previous ſwelling. After the operation of removing a cancerous eye, a malignant fungus often ariſes from the bottom of the orbit, increaſes notwithſtanding the moſt able interference of the ſurgeon, affects the brain, and deſtroys the patient. After cutting out a circular piece of the ſkull with a trephine, and expoſing the dura mater, it ſometimes

happens

happens that a dangerous fungus ſhoots up from the outer ſurface of the latter membrane. Whenever there is a diſeaſed or exfoliating portion of bone under any ſore, fungous granulations are particularly prone to appear, and, in this inſtance, the cure depends on the ſeparation of the morbid part underneath. When a ſurgeon ventures to cut away any tumour, which is growing cloſely connected with a tendinous expanſion, he ſhould be on his guard againſt the production of a fungus. This remark ſhould be remembered, after taking away ganglions with a cutting inſtrument. After operations for cancerous diſeaſes, the appearance of a fungus is the principal uneaſineſs of every well-informed practitioner, who, in beholding the high, luxuriant, ſpongy granulations, recognizes the recurrence of the fatal diſtemper.

Before entering into the conſideration of ſeveral important fungous diſeaſes, which form the chief ſubject of the preſent article, we have to remark, that the treatment of a fungus, whatever be the ſpecies, generally conſiſts in attempting to extirpate it. For the moſt part, the ſooner ſuch endeavour is made, the more likely it is to ſucceed, and the leſs formidable is the operation. The extirpation is effected ſometimes with a cutting inſtrument, ſometimes with cauſtic, ſometimes with a ligature. In former times, the actual cautery was much employed for this purpoſe, and it appears to be not altogether abandoned in France even in our own times; but, by the general conſent of all reſpectable practitioners, hot irons have long been diſuſed in the practice of ſurgery in England.

Fungus of the Antrum.—Anatomy teaches us, that the antrum is a conſiderable cavity, ſituated in the upper jaw-bone, between the lower part of the orbit and the roof of the mouth, having an aperture, by which it communicates with the inſide of the noſe, and being lined with a production of the Schneiderian membrane.

Fungous diſeaſes of the antrum are amongſt the moſt terrible to which human nature is ſubject. The dreadful ſufferings and extenſive miſchief which a tumour of this deſcription may induce, have been excellently depicted in the following narrative. M. T. David, fifty years of age, experienced for two years a degree of violent pain, which he referred to the two large molar teeth of the right ſide of the upper jaw. Theſe teeth were extracted in the month of September, 1790, without any relief being obtained. Towards the end of February, 1791, the cheek of the ſame ſide was affected with ſwelling and pain. A ſhort time afterwards, a ſoft ſmall eminence appeared above the tuberoſity of the cheek-bone, and, as it increaſed rapidly, the patient was determined to try to get into the Hôtel-Dieu on the 30th of the following April. At this period the whole cheek was ſwelled, red, and painful; the tumour on the cheek-bone was about two inches in diameter, and, by projecting into the orbit, had puſhed the globe of the eye upwards and backwards. A portion of the fungus filled up the right noſtril, puſhed the ſeptum naſi to one ſide, and protruded to the extent of half an inch from the anterior opening. That part of the alveolar proceſs, from which the teeth had been extracted, being depreſſed below the level of the remaining teeth, rendered maſtication extremely difficult. From the weakneſs and advanced age of the patient little hope of a cure was entertained. With a view of palliating the pain in the cheek, compreſſes, moiſtened with the lotio aquæ lithargyri acetati, were applied.

During the firſt fortnight, the ſwelling over the cheek-bone only underwent a trivial augmentation; but the fungus increaſed with great rapidity. It extended towards the back part of the noſtrils, depreſſed the arch of the palate, and deformed the noſe ſo much, that it could ſcarcely be diſtinguiſhed from the cheek. The pains became more and more aggravated, and, at laſt, deprived the patient of her ſleep. Toward the end of the firſt month, that portion of the fungus which had paſſed out of the right noſtril returned into the noſe. The tumour alſo, which projected into the mouth, partly diſappeared; but the ſwelling on the tuberoſity of the cheek-bone conſiderably increaſed. The eye-ball ſoon became entirely concealed in the orbit; the ſkin of the cheek became gradually thin, and, at length, burſt by a ſmall opening ſituated under the great angle of the orbit. From this orifice a great quantity of reddiſh ſanies was diſcharged. A fortnight afterwards, an ulceration took place at the top of this tumour, and gave vent to a putrid and very irritating ſanies. The pains now extended towards the ear, from which flowed a quantity of fœtid, blackiſh pus. The ulcer produced a deep excavation in the cheek, which, in leſs than ten days, was entirely deſtroyed. A colliquative diarrhœa now came on, and the patient died in a ſtate of maraſmus on the 4th of July, ten weeks after her admiſſion, and three years from the commencement of her complaint. On diſſection, the muſcles of the right ſide of her face were found reduced to a thick yellow cellular maſs. The pterygoid, maſſeter, and temporal muſcles were in part deſtroyed, as it is ſaid, by the corroſive action of the ſanious diſcharge, which even made an impreſſion on the finger. The ligaments which connected the lower jaw to the temporal bone were deſtroyed, and the pus paſſed through an opening from this articulation into the meatus auditorius externus. The right portion of the palatine arch, and three-fourths of the poſterior alveolar proceſs, were of the conſiſtence of cartilage. The external part of the orbit was deſtroyed by the fungus. The apophyſis of the maxillary bone was diſlocated, and, in part, deſtroyed. The articulation of the cheek-bone with the temporal bone was ſo nearly annihilated, that there only remained a connection by means of a thin lamina, in which were ſeveral openings. The right partition of the naſal foſſa was deſtroyed, and the antrum formed with the noſe one large cavity. See Deſault's Pariſian Chirurgical Journal, vol. ii.

Such is the dreadful progreſs of fungous tumours of the antrum, when left to themſelves, and unreſiſted by the ſalutary and timely interference of ſurgery. One ſingle example, indeed, is inſufficient for conveying a full idea of the ravages which may be occaſioned by the increaſe of the fungus and its preſſure on the ſurrounding parts. In ſome caſes, the ſwelling prevents the tears from paſſing down into the noſe, raiſes the lower part of the orbit, cauſes a protruſion of the eye, occaſions an irremediable loſs of ſight, makes the grinding teeth fall out, obliterates the neighbouring noſtril, and produces an expanſion and a partial abſorption of the bony parietes of the antrum itſelf. The ſufferings of a patient afflicted in this manner baffle deſcription. His headaches are terrible and inceſſant; he breathes with difficulty; he is deprived of his ſleep and appetite; he lingers in a miſerable ſtate of weakneſs, loathſomeneſs, deformity and pain, and dies at once an object of pity and diſguſt.

Fungi of the antrum are not diſeaſes with which we can tamper or play with impunity. They are not caſes which hold forth any chance of ſpontaneous amendment or cure. On the contrary, it is their nature to grow continually worſe, and to bring on the fatal termination which happened in the inſtance above related. Knowing theſe things, every ſurgeon who values his own profeſſional reputation, or the life

life of his patient, will immediately make up his mind to act with promptitude and deciſion. In the early period of the diſeaſe the tumour itſelf is the only thing which requires removal; but after the ſwelling has brought on the train of ravages which we have above enumerated, a cure cannot be accompliſhed in ſo eaſy a manner. We may, indeed, take away the fungus, and put a ſtop to the increaſing miſchief; yet many of the changes which have been occaſioned muſt take a long time to be rectified, and ſome of the effects, ſuch as the deſtruction of the ſight, may have become totally incurable.

The longer the diſtemper has exiſted, the more extenſive will generally be the ſurrounding miſchief, and the more likely will the fungus be to grow again. Even when this reproduction of the excreſcence does not happen, many months and years will often be required for the completion of the cure, the ſeparation of the exfoliations, the healing of ulcers and ſinuſes, and the re-eſtabliſhment of the health.

After ſtating theſe circumſtances, it becomes almoſt ſuperfluous to enjoin ſurgeons to endeavour to diſcover the diſeaſe in its infancy, and to attack it in this ſtate with powerful and effectual means.

Fungi of the antrum appear frequently to originate from the irritation of carious teeth in the upper jaw. From this cauſe, from bad colds in particular habits, from blows, or on ſome other inexplicable account, we conceive that the Schneiderian membrane which lines the cavity is inflamed, throws out coagulating lymph, and emits the deſtructive fungous excreſcence.

Now, by reaſon of the concealed ſituation of ſuch a tumour, it muſt be ſomewhat difficult to make out the nature of the affection before it has made a certain progreſs, eſpecially as the complaints are uſually regarded at firſt as common tooth-achs, or mere rheumatic pains of the face.

Hence, whenever a practitioner is conſulted for theſe caſes, he ſhould at leaſt take the trouble to aſk a few prudent queſtions; for notwithſtanding the inviſible ſituation of a fungus in the antrum, it is well known among all well-informed ſurgeons that ſuch a diſtemper ſeldom exiſts without being attended with ſome affections of the adjacent parts. It is by conſidering theſe latter complaints that we are led to ſuſpect a tumour in the antrum, and that we are ſometimes enabled to aſcertain its preſence before it has become ſo large as to occaſion much diſfigurement of the face, or any alarming degree of ſurrounding miſchief. The ſurgeon ſhould enquire whether any of the teeth have become looſe, or have ſpontaneouſly fallen out; whether the alveolar proceſs is ſound; whether there are any fungous granulations making their appearance at the ſockets of ſuch teeth as may have dropped out of, or been extracted from the upper jaw; whether there is any diſcharge of ſanies, or matter from the noſe, &c. Whenever ſuch ſymptoms prevail, there is great reaſon to ſuſpect that a fungus exiſts in the antrum, and the ſurgeon ſhould not remain inactive, till the bones of the face begin to ſwell, fungi protrude through the ſkin of the cheek, the eye is diſplaced, the ductus naſalis obſtructed, and the ſurrounding miſchief has become alarmingly extenſive.

If the patient, with any of the preceding grounds of ſuſpicion, ſhould labour under violent and long-continued pain in the ſituation of the upper jaw-bone, after having had bad teeth, a ſevere cold, or a blow on the face, the practitioner is called upon to make an opening into the antrum, for the purpoſe of being able to get at the very root of the tumour.

There are two ſituations in which the ſurgeon may effect this object. One is to make a perforation with a gimblet, or ſome ſuch inſtrument, through the ſocket of any diſeaſed grinding tooth which may happen to be ſituated under the antrum, and which of courſe muſt be in the firſt inſtance extracted. We need not dwell upon the propriety of taking out a carious tooth in theſe caſes inſtead of a ſound one. When none of the teeth are bad, which will very ſeldom happen with a fungus in the antrum, and when the ſurgeon is determined to make an opening by drawing one of the teeth, and perforating the bottom of the ſocket, his beſt plan is to extract the third or fourth grinder, reckoning from before backward.

We will not poſitively condemn the plan of making an opening into the antrum in the foregoing way. It may be right in the firſt inſtance, before the ſurgeon is certain whether the diſeaſe is a tumour or an abſceſs in that cavity; becauſe, in the latter event, the method will be likely to anſwer every purpoſe; and ſhould there be a fungus preſent, the removal of a bad tooth, and perforation of the ſocket, cannot do any harm. Indeed we may adviſe, as a general practice, that in every inſtance in which a patient ſuffers violent pain in the face, and has any carious teeth, theſe ſhould always be taken out without the leaſt delay.

Although we have not ventured to diſſuade practitioners altogether from taking this mode of making an opening into the antrum, we have no heſitation in declaring, that, in the event of there being a fungus in that cavity, ſuch an opening will not be ample enough to enable the ſurgeon to put in execution the beſt meaſures for the effectual extirpation of the tumour; he may, indeed, by means of the perforation, give vent to ſome ſanies, aſcertain that the caſe is not an abſceſs, diſturb the excreſcence with his probe, &c.; but he will not be able to attack the diſeaſe at its root, and unleſs this be done, he had better remain quiet. The only reaſons, therefore, in favour of making, in the firſt inſtance, a perforation through the alveolar proceſs, are, that the ſurgeon may learn with certainty that the caſe is not an abſceſs, and that the patient, at all events, thus gets rid of a carious tooth, which may be looked upon as a ſource of irritation and pain.

As ſoon as the ſurgeon is convinced of the exiſtence of a fungus in the antrum, he ſhould immediately decide to make ſuch a free expoſure of the excreſcence as will enable him to put in practice its effectual extirpation. Let him at once determine to imitate the immortal Deſault in deciſion and boldneſs in theſe urgent caſes, to tamper and play with which is even far more culpable and abſurd than leaving the unhappy patient to his own fate.

Deſault had a patient with a fungus, which had grown in the antrum, diſtended the parietes of that cavity, hindered the tears from paſſing down into the noſe, raiſed the lower part of the orbit, cauſed a protruſion of the eye, made two of the grinding teeth fall out, and cauſed in the anterior part of the antrum a cavity, from which a portion of the excreſcence projected. The following was the plan of treatment, which was ſucceſsfully adopted. The cheek was firſt detached from the os maxillare, by dividing the internal membrane of the mouth, at the place where it is reflected over this bone. Thus, the outer ſurface of the bone was denuded of all the ſoft parts. A ſharp, perforating inſtrument was applied to the middle of this ſurface, and an opening made more forward than the one already exiſting. The plate of bone, ſituated between the two apertures, was removed with a little falciform knife, which, being directed from behind forward, made the diviſion without difficulty. The opening, thus obtained, being inſufficient, Deſault endeavoured to enlarge it below, by ſacri-

ſcing the alveolary proceſs. This he endeavoured to accompliſh with the ſame inſtrument, but finding the reſiſtance too great, he had recourſe to a gouge and mallet. A conſiderable piece of the alveolary arch was thus detached, without any previous extraction of the correſponding teeth, three of which were removed by the ſame ſtroke. In this manner an opening was procured in the external and inferior part of the antrum, large enough to admit a walnut. Through this aperture a conſiderable part of the tumour was cut away with a knife, curved ſideways and fixed in its handle. A moſt profuſe hemorrhage took place, but Deſault, unalarmed, held a compreſs in the antrum for a ſhort time; this being removed, the actual cautery was applied repeatedly to the reſt of the fungus. The cavity was dreſſed with lint, dipped in powdered colophony.

On the eighteenth day the ſwelling was evidently diminiſhed, the eye leſs prominent, and the epiphora leſs viſible. But at this period a portion of fungus made its appearance again. This was almoſt entirely deſtroyed by applying the actual cautery twice. It appeared again, however, on the twenty-fifth day, and required a third and laſt recourſe to the cautery. From this time the progreſs of the cure went on rapidly. Inſtead of fungous excreſcences, healthy granulations were now formed in the bottom of the ſinus. The parietes of the antrum gradually approaching each other, the large opening made in the operation was obliterated, and reduced to a ſmall aperture, hardly large enough to admit a probe. Even this little opening was cloſed in the fourth month, at which time no veſtiges of the diſeaſe remained, except the loſs of teeth, and a very obvious depreſſion juſt where they were ſituated. (Œuvres Chirurgicales de Deſault, par Bichat, tom. 2.)

Some readers may deem ſome of the foregoing meaſures rude and violent. The ſtriking out of three of the teeth with a portion of the alveolar proceſs, and the employment of the actual cautery, are undoubtedly very rough proceedings, and cannot be expected to receive the approbation of many ſurgeons in this country. Nor will we abſolutely declare in favour of theſe methods, much as we are convinced of the neceſſity of having recourſe to powerful means, and greatly as we admire the boldneſs and deciſion which guided the hand of Deſault. We conſider the uſe of the perforator and falciform knife, however, deſerving of recommendation. In ſome inſtances a ſmall trephine might be uſed for making an opening into the antrum. Even the removal of a part of the alveolar arch muſt be effected if the root of the excreſcence cannot otherwiſe be reached. Perhaps one of the ſaws, deſcribed and engraved in Mr. Hey's Practical Obſervations in Surgery, might be the beſt inſtrument for accompliſhing this object; but rather than that the purpoſe ſhould not be fulfilled, if a ſufficient expoſure of the fungus cannot otherwiſe be obtained, we conſider even Deſault's plan indiſpenſably proper, on account of the terrible and fatal miſchief which muſt inevitably follow the continuance of the diſeaſe. With regard to the employment of the actual cautery, ſurgeons may eaſily avoid the diſagreeable duty of applying hot irons, by uſing, inſtead of ſuch barbarous implements, the kali purum, with or without the calx viva. After cutting away as much of the fungus as poſſible, the ſurface from which its root aroſe ſhould be freely rubbed with the cauſtic, ſo as to obviate the danger of the excreſcence growing again. If, however, any fungous granulations ſhould re-appear, the ſurgeon muſt take care to extirpate them immediately with the knife and cauſtic. In all probability ſuch ſteps will kill a portion of the bone; but who would not rather ſubmit to the tedioufneſs of an exfoliation than to the re-production of a terrible diſeaſe, which is equally loathſome, deforming, and painful, holds forth no chance of ſpontaneous amendment, and tends to a ſhocking ſpecies of death?

Fungus Cerebri, or Hernia of the Brain.—This is a totally different diſeaſe from the excreſcences which ſometimes grow from the dura mater, and make their way outward by producing an abſorption of the ſuperincumbent part of the ſkull, and an ulceration of the integuments of the head. Such fungi, for the moſt part, begin while the cranium is entire, and the deſtruction of the bone is a conſequence of the increaſe of the ſubjacent ſwelling. On the other hand, the fungus, or hernia cerebri, follows a removal or deſtruction of a piece of the ſkull, and conſequently, when the diſeaſe occurs, it is almoſt always after the operation of trepanning, though, if Mr. Charles Bell's account be accurate, the ſame kind of tumour may alſo be a conſequence of a venereal caries of the cranium.

Mr. Abernethy has publiſhed an intereſting caſe, and offered the following theory of the formation of the diſeaſe: "In conſequence of the brain being injured to ſome depth beneath the ſurface, diſeaſe of the veſſels, and conſequent effuſion of blood had enſued. The effuſion was, for a time, reſtrained by the ſuperincumbent brain and its membranes; but theſe gradually yielding to the expanſive force exerted from within, and at laſt giving way altogether, the fluid blood oozed out, and congealed upon the ſurface of the tumour." Hence Mr. Abernethy appears to ſuppoſe that the excreſcence is compoſed of a mere maſs of congealed blood, and the rapidity with which the ſwelling aroſe in the caſe which he diſſected made him think that there was not time enough for any organized vaſcular ſubſtance to be formed.

However, we cannot help ſuſpecting that the fungus cerebri is vaſcular, like other tumours, and when Mr. Abernethy mentions, in the relation of the example which he diſſected, the irregularly *granulated* ſurface of the ſwelling, we cannot conceive how ſuch a ſtructure could be an accidental conſequence of a mere exudation of blood.

Mr. Charles Bell, in his Operative Surgery, vol. i. expreſſes his opinion that the deficiency of the ſkull, and the ulceration of the dura mater, always precede the growth of the fungus, that after large openings made in the cranium with the trepan, or the elevation of extenſive depreſſed pieces of the ſkull, the pulſation of the brain forces the dura mater againſt the ſharp edge of the bone, and makes that membrane ulcerate; and that then a fungus rapidly ſprouts up from the ſubſtance of the brain, which has a tendency to ulceration.

In proof of the vaſcularity of the fungus, ſeveral circumſtances are mentioned by the foregoing writer. The tumour bleeds when torn or cut. It ſhrinks and collapſes when the patient dies. Mr. Charles Bell has a preparation of the diſeaſe, where an ulcer paſſes from its baſe into the lateral ventricle, and where the ulcer has an external opening, yet no blood, nor coagulum, was found upon the ſurface of the brain, or in the cavities. The ſwelling is not formed of concentric laminæ, like the coagulum of an aneuriſm. The blood never burſts from its ſurface as it would do even from a venous tumour, which could in the firſt inſtance make its way through the membranes of the brain. It is affected, like ſpongy granulations, by cauſtic. A degree of compreſſion, ſuch as would ſtop bleeding from a conſiderable artery, will not ſubdue the diſeaſe when it has made ſome progreſs. The ſwelling has a fibrous ſtructure, and when diſſolved after death, hangs in ſhreds, not like a coagulum.

In a caſe of fungus cerebri, which fell under Mr. Charles Bell's obſervation, and aroſe after a venereal exfoliation of

the ſkull, the following ſymptoms occurred: At the beginning, while ſenſibility laſted, the patient uſed to have cold ſhiverings and pain in the head. His countenance was of a pale, dirty, cadaverous yellow. As the tumour increaſed, he had frequent ſickneſs, was ſubject to giddineſs, and reeled like a drunken man; the pulſe became ſlow and weak; he betook himſelf entirely to his bed, could no longer ſit up, became incoherent, lay oppreſſed, and had a pulſe which was a mere tremulous motion of the artery. The diſeaſe ran its courſe in about eight days.

With regard to the treatment of the fungus cerebri, Mr. Abernethy is of opinion, that when no bad ſymptoms precede the appearance of the tumour, or when they go away upon the ſwelling being freed from the confinement of the dura mater, it may perhaps be moſt prudent not to interfere with the diſeaſe. The tumour may of itſelf drop off in pieces, and be no more renewed. In the Edinburgh Medical Commentaries, vol. i. p. 98, may be found a caſe, in which the tumour continued to increaſe for fourteen days, and had become as large as a gooſe's egg, when it dropped off in largiſh pieces. Another inſtance of the ſame kind is alſo recorded in the Medical Muſeum, vol. iv. p. 463. See likewiſe Fabricius Hildanus.

While the tumour is unattended with any urgent ſymptoms, it only ſeems neceſſary to cover the ſwelling and ſore with ſome mild dreſſing, carefully avoiding all preſſure, which both reaſon and experience ſhew is likely to be attended with bad conſequences.

However, if the fungus ſhould continue to increaſe very much, ſo as to make it almoſt impoſſible to avoid making preſſure upon it, the plan, which experience appears to approve the moſt, is occaſionally to pare off the tumour with a knife.

That ſuch ſwellings may be ſucceſsfully removed has been proved both by accidents and by practice. Du Queſnay, in the Mémoires de l'Academie de Chirurgie, relates the following caſe: A young man received, on the right parietal bone, a blow which cauſed a fracture. A part of the bone was taken away, and a hernia cerebri enſued, which was ſeveral times pared down with a knife. On the thirty-fifth day from the accident, the patient, in a ſtate of intoxication, put his hand under the dreſſings, and tore the protruding portion of the tumour violently away. The next day the ſurgeon found that almoſt the whole of what he conſidered as corrupted brain was removed, ſo deep a cavity being left, that the corpus calloſum could almoſt be ſeen. The place healed up completely; but a palſy of the left ſide of the body, which had come on the day after the accident, ſtill continued.

Several examples are recorded by Mr. Hill of fungi of the brain being ſucceſsfully pared down with a knife. (See Caſes in Surgery).

When a fungus cerebri, in conſequence of being confined by the ſmallneſs of the aperture in the bone, occaſions irritation and preſſure on the brain, it may be adviſable to enlarge the opening in the cranium. In this way, the ſurgeon may alſo ſucceed in giving vent to fluid collected and confined under the ſkull.

There are ſome caſes to be met with, in ſurgical books, greatly againſt the employment of compreſſion. One is noticed by Scultetus, in his Armamentarium Chirurgicum, obſ. 19; and another in the London Medical Journal, vol. x. p. 277. In theſe inſtances compreſſion was tried, for the purpoſe of ſtopping the growth of the tumour; but both the patients died. Upon diſſection, a large cavity was found in each brain, filled with an accumulation of fluid, which had been prevented from eſcaping, by reaſon of the opening in the bone being cloſed by the fungus.

Were a caſe to preſent itſelf, in which the degree of hemorrhage from a fungus cerebri was dangerous, Mr. Abernethy has propoſed the plan of removing the ſubſtance of the ſwelling, and expoſing the bleeding veſſels, in order to ſee whether this expoſure would put a ſtop to the bleeding. This gentleman conſiders the experiment juſtified by analogy; for bleeding in other ſituations will often continue notwithſtanding the preſſure of the dreſſings and large coagula; but will immediately ceaſe on the bleeding ſurface being expoſed.

We ſhall conclude with cautioning ſurgeons againſt the danger of ever applying ſtyptics and cauſtics to any diſeaſes ariſing from the ſurface, or ſubſtance of the brain, and with adviſing them not to let the fungus draw away their attention from every other circumſtance. Frequently, inflammation of the pia mater will be co-exiſtent with the latter diſeaſe, and require at leaſt as much vigilance, deciſion, and judgment on the part of the ſurgeon.

Fungus Teſtis.—Until lately, the particular diſeaſe of which we are about to ſpeak ſeems to have eſcaped the notice of ſurgical writers, and in conſequence of the affection not being underſtood, when met with in practice, the ſevere proceeding of caſtration has too often been very unneceſſarily adopted.

An exceedingly able deſcription of the fungus teſtis was publiſhed by Mr. Lawrence in the fourth volume of the Edinburgh Medical and Surgical Journal. The ſubject is there illuſtrated with the particulars of nine caſes, which fell under the author's obſervation.

It is ſtated by this gentleman, that the patient commonly aſſigns ſome blow, or other injury, as the cauſe of the complaint. In ſome inſtances, the diſeaſe originates in the hernia humoralis from gonorrhœa; in others it comes on without any apparent cauſe. The diſorder begins with an extremely hard painful ſwelling of the teſticle. After a certain ſpace of time the ſcrotum ulcerates; but the opening which is thus formed, inſtead of diſcharging matter, gives iſſue to a firm and generally inſenſible fungus. The ſurrounding integuments and cellular ſubſtance are thickened and indurated by the complaint, ſo that there appears altogether a conſiderable maſs of diſeaſe. As ſoon as the ſcrotum has burſt, a conſiderable diminution of the pain and ſwelling takes place. In this ſtate the diſorder appears very indolent; but if the fungus be deſtroyed by any means, the integuments come together, and a cicatrix enſues, which is inſeparably connected with the teſticle.

Mr. Lawrence next informs us, that an examination of the part, while the fungus exiſts, diſcloſes the fact, that this growth has its origin in the glandular ſubſtance of the teſtis itſelf; that the coats of the part are deſtroyed to a certain extent; and that a protruſion of the tubuli ſeminiferi takes place through the opening, which is thus formed. "I have often (ſays this gentleman) aſcertained the continuity of the excreſcences with the pulpy ſubſtance of the teſtis, of which we ſhall find more or leſs remaining, according to the difference in the period of the diſorder. It appears to me that the glandular part of the teſtis experiences an inflammatory affection in the firſt inſtance, in conſequence of the violence inflicted on it; and that the confinement of the ſwollen ſubſtance, by the denſe and unyielding tunica albuginea, ſufficiently explains the peculiar hardneſs of the tumour, and the pain which is always attendant on this ſtage of the diſorder. The abſorption of the coats of the teſtis and of the ſcrotum obviates the tenſion of the parts, and thereby reſtores eaſe to the patient, at the ſame time that the fungus makes its appear-

appearance externally. I think it not improbale, that if the complaint were left entirely to itſelf, the ſwelling would ſubſide, the fungus ſhrink, and a complete cure enſue, without any profeſſional aſſiſtance; but the diſorder is ſo indolent in this ſtage, that a ſpontaneous cure would not be effected until after a very long time. The excreſcence may, however, be removed by the knife, or, if the nature of its attachment permit, by ligature; or it may be freely treated with eſcharotic applications. The removal of the protuberance to a level with the ſcrotum, by means of the knife, is the ſhorteſt and moſt effectual mode of treatment. I can ſee no ground whatever for propoſing caſtration in this malady, ſince in no part of its progreſs, nor in any of its poſſible conſequences or effects, can it expoſe the patient to the ſlighteſt riſk. Some may be diſpoſed to defend the removal of the part, becauſe it would bring the caſe to a more ſpeedy termination, and if a patient, after being informed of all the circumſtances, ſhould deſire the operation on this ground, the ſurgeon would be juſtified in performing it. But I think he never could be warranted in propoſing ſo painful and dangerous a remedy as caſtration, for a diſorder attended with neither pain nor danger, and admitting of cure by a perfectly ſafe and mild kind of treatment.

"Funguſes of a different character and progreſs may, no doubt, occur in the teſtis; but the deſcription already given will ſerve to diſcriminate that particular ſpecies, to which alone the preſent obſervations are deſigned to apply. In a caſe, in which my friend Mr. Macartney performed the operation of caſtration, the teſtis itſelf was found, and the fungus, which was a firm and denſe ſubſtance, grew from the tunica albuginea."

Mr. Lawrence proceeds to mention, that ſome authors have recorded caſes which bear a ſlight analogy to the fungus teſtis, of which we have been ſpeaking. Petit and Swediaur are ſtated to have deſcribed the diſcharge of ſmall portions of the ſubſtance of the teſticle from an abſceſs of the part. (See Mem. ſur la Suppuration de la Membrane propre de Teſticule in Mem. de l'Acad. de Chirurgie, tom. 4. and Obſervations on Venereal Complaints.) Bertrandi deſcribes the ſame occurrence, and the ſubſidence of a protruded part under the uſe of ſtimulant powders. (See Mem. de l'Acad. de Chirurgie, tom. 5. p. 677.) Sabatier mentions the ſwelling and burſting of the teſticle, and eſcape of a part of its ſubſtance, as occaſionally occurring in the radical cure of the hydrocele. (Mem. de l'Acad. de Chirurgie, tom. 3.)

The caſes of the fungus teſtis, publiſhed by Mr. Lawrence, are well deſerving of attention, as they afford a very ſatisfactory explanation of the nature of the diſeaſe. The performance of caſtration for the cure of this malady ought, in our opinion, never to be thought of. Even when the patient himſelf has had the nature of the caſe explained to him, and wiſhes to ſubmit to the operation with a view of getting ſpeedily well, we conſider that the removal of the teſtis is not at all neceſſary in the cure, and that were this ſevere method adopted, it would not be the moſt expeditious means of relief. Cutting away the prominent part of the fungus, and freely rubbing the deeper portion of it with cauſtic, will certainly deſtroy the diſtemper, and, after this practice, we ſhall have no extenſive wound of the ſcrotum to heal up, as would be the caſe were caſtration performed. Hence it appears to us, that the removal of the teſticle is warranted by no conſiderations whatever, not even by the earneſt intreaties of the patient. Such a wiſh can only ariſe from not knowing that the diſeaſe may be got rid of, with at leaſt equal quickneſs, by a much milder plan of treatment. We ſhall take our leave of this ſubject with referring our readers to the caſes recorded by Mr. Lawrence. (See Edinburgh Medical and Surgical Journal, vol. iv. p. 257.)

Fungus Hæmatodes.—This is one of the moſt intractable diſeaſes to which the human frame is liable. Terrible as the diſtemper is, however, it was not conſidered as a caſe of a diſtinct and peculiar nature, until Mr. Burns, of Glaſgow, gave ſome account of the ſubject in the ſecond volume of his work on inflammation. The diſorder is there deſcribed under the name of *ſpongoid inflammation*, and, at preſent, it is known by ſome other appellations, ſuch as the *ſoft cancer*; *medullary ſarcoma*, and *carcinome ſanglante*.

Before Mr. Burns publiſhed the above-mentioned book, the fungus hæmatodes was always miſtaken for cancer, and we may indeed ſtate, that the ſame error generally continued to prevail, until Mr. Hey's "Practical Obſervations in Surgery" iſſued from the preſs in the year 1803. How different the two diſeaſes are, will be clearly ſhewn in the ſequel of the preſent article.

The fungus hæmatodes has moſt frequently been obſerved to make its attack on the eye-ball, the upper and lower extremities, the teſticle, and the mamma. Mr. Wardrop ſtates, that the uterus, ovary, liver, ſpleen, lungs, and thyroid gland, have alſo been the ſeats of the diſeaſe, and Mr. Burns has recorded one example, in which the hip-joint was the part affected. The joint of the ſhoulder likewiſe appears to be ſubject to the malady, as is proved by ſome drawings in the collection of the Ecole de Médecine, ſhewing ſpecimens of what the French have named the "carcinome ſanglante", which is plainly the ſame affection as the fungus hæmatodes.

A diſtemper, which makes its attack on ſo many different parts and organs, cannot always preſent itſelf exactly in the ſame form. Hence, it ſeems expedient to offer a conciſe account of the manner in which the malady occurs in various ſituations, more particularly the eye, extremities, female breaſt, and teſticle.

According to Mr. Wardrop, the firſt appearances of the fungus hæmatodes, when it attacks the eye, are in the poſterior chamber. The pupil becomes dilated and immoveable, and, inſtead of having its natural deep black colour, it has a dark amber, and, in ſome caſes, a greeniſh hue, giving to the eye much of that appearance which exiſts in the ſound eye of a ſheep or cat. As the diſeaſe advances, the colour becomes more remarkable, and, at length, is diſcovered to be occaſioned by a ſolid ſubſtance, proceeding from the bottom of the eye towards the cornea. The ſurface of this ſubſtance is generally rugged and unequal, and, in ſome caſes, red veſſels may be ſeen running acroſs it. Theſe are ramifications of the central artery of the retina, ſituated in front of the opaque body. In proportion as the diſeaſe makes progreſs, the new-formed ſubſtance gradually fills up the whole of the poſterior chamber, and its ſurface advances as far forward as the iris. In this ſtate, the diſeaſe has the appearance of an amber, or a brown maſs, and, in two inſtances, which Mr. Wardrop was acquainted with, the exiſtence of cataracts was ſuſpected, and couching in one example actually undertaken by an experienced ſurgeon.

The diſeaſe continuing to increaſe, an alteration next takes place in the ſhape of the eye-ball, which acquires an irregular knobbed appearance. At the ſame time the ſclerotic coat loſes its natural pearly-white colour, and becomes of a dark blue, or livid hue. The tumour now occupies the whole anterior chamber, and, in ſome caſes, a quantity of purulent matter collects between the diſeaſed maſs and

the cornea. At laſt, the cornea ulcerates, and a fungous tumour ſhoots out. In certain inſtances, the ſwelling makes its way through the ſclerotic coat.

Mr. Wardrop notices, that the fungus to which we have juſt now adverted is very rapid in its growth, and often acquires a conſiderable bulk. When ſmall, it bears a near reſemblance to a ſoft polypus. It is generally of a dark red, or purple colour. Its ſurface is irregular and often covered with coagulated blood. Its ſubſtance is eaſily torn, and on being broken, or ſlightly ſcratched, a profuſe hemorrhage takes place. In particular caſes, the fungus is of a firmer texture. When the ſwelling happens to protrude through the ſclerotic coat, it receives a covering from the tunica conjunctiva. When the fungus has attained a large ſize, the moſt prominent parts ſlough away, attended with a very fœtid ſmell, and a diſcharge of acrid ſanies.

In the courſe of the diſeaſe the lymphatic glands become affected, particularly thoſe which lie about the parotid gland, and under the lower jaw.

When an eye, affected with the fungus hæmatodes, in an advanced ſtate, is diſſected, a diſeaſed maſs is found extending forwards from the entrance of the optic nerve in ſuch a manner as to have produced an abſorption of the vitreous, cryſtalline, and aqueous humours. The retina is, as it were, annihilated, while the choroid coat is propelled forward, and ſometimes quite deſtroyed.

The ſubſtance of the excreſcence itſelf has the appearance of medullary matter, being chiefly compoſed of an opaque, whitiſh, homogeneous matter, having the ſame pulpy ſoftneſs and tenacity which characterize brain. It varies, however, both in conſiſtence and colour in different caſes, and ſometimes contains bony particles.

The optic nerve is thicker and harder than natural, of a browniſh aſh-colour, and deſtitute of the tubular appearance which it ought to have. In other caſes, the nerve, beſides being altered in its ſtructure, is ſplit into one or more pieces, the morbid growth filling up the interſpaces, ſurrounding the different portions of the nerve, and forming one connected maſs with the contents of the eye-ball. Other changes have been remarked in the nerve; but they muſt be learnt by a reference to Mr. Wardrop's publication.

The brain and its membranes have alſo been obſerved to ſhare the diſeaſe. Dark red ſpots have been noticed on the dura mater, and, in other examples, white ſpots were found between the tunica arachnoides and pia mater, which were ſcattered almoſt all over the ſurface of the brain, and proved to be ſmall bags, containing a fluid like cream.

When the abſorbent glands are enlarged, they are found converted into the ſame kind of medullary matter, which compoſes the diſeaſed maſs in the eye-ball. Should the ſkin burſt, a ſloughy ulcer is produced; but, according to Mr. Wardrop, no fungus ſhoots out, unleſs when the affection of a lymphatic gland is itſelf a primary one.

In conſidering the fungus hæmatodes of the eye, every reader muſt be ſtruck with the very early period of life at which the diſeaſe generally commences. Of twenty-four caſes with which Mr. Wardrop has been acquainted, twenty were under twelve years of age, and it is ſtated, in "Les Œuvres Chirurgicales de Deſault, par Bichat," tom. 2, that two-thirds of the patients, on whom Deſault operated for carcinoma of the eye, at the Hotel-Dieu, were under twelve years of age. Now as cancer is always moſt diſpoſed to attack perſons advanced in life, we may conclude, that Deſault's patients, for the moſt part, laboured under the fungus hæmatodes, from which, indeed, cancer has not been diſcriminated by moſt of the beſt ſurgical writers.

The ſight of young ſubjects is generally deſtroyed before the attention of parents is excited to the diſtemper. In many caſes, however, the eye firſt receives a blow, which brings on inflammation, and after the ophthalmy has laſted a certain time, the coloured ſubſtance becomes perceptible at the bottom of the eye. When no external violence has occurred, the firſt ſymptom is a trivial fulneſs of the veſſels of the conjunctiva, the iris becoming, at the ſame time, extremely vaſcular, and altered in colour, and the pupil dilated and immoveable. There is ſeldom much complaint made of pain; but the child is ſometimes obſerved to be languid and feveriſh.

In adults, the fungus hæmatodes of the eye generally comes on without any apparent cauſe, though ſometimes in conſequence of a blow. At firſt, the tunica conjunctiva is ſlightly reddened, and viſion is indiſtinct. The redneſs and obſcurity of ſight increaſe ſlowly, and an aching pain is experienced in the head. The latter ſymptom is deſcribed as being moſt agonizing, particularly during the night, and never becoming diminiſhed, until the eye burſts and the humours are diſcharged. Only one eye is in general affected.

With regard to the cure of the fungus hæmatodes of the eye, the only chance of effecting this deſirable object depends upon the early extirpation of the diſeaſed organ. It muſt be acknowledged, however, that moſt of the operations, in which the morbid eye has been removed, have hitherto proved unſucceſsful, owing to a recurrence of the diſeaſe. The reaſon of this circumſtance may be imputed to the optic nerve being almoſt always in a morbid ſtate, before any attempt is made to remove the eye. Mr. Wardrop remarks, that paſt experience proves the impropriety of attempting any operation, when the diſeaſe has advanced ſo far that the poſterior chamber is filled with the diſeaſed growth. Since no internal medicines, nor external applications, ſeem to afford the leaſt hope of checking any form of the fungus hæmatodes, it is obvious, that when the diſeaſe of the eye has exceeded certain bounds, the miſerable patient is placed beyond the reach of any effectual aid from ſurgery.

We ſhall conclude our remarks on fungus hæmatodes of the eye, with referring the reader to a late valuable publication, entitled "Obſervations on Fungus Hæmatodes," by James Wardrop, 1809. In this book many caſes, and numerous particulars, relative to the morbid anatomy of the diſeaſe, are ably deſcribed.

When fungus hæmatodes affects any part of the limbs, the diſeaſe generally commences with a ſmall colourleſs tumour, which, if there be no thick covering over it, ſuch as the faſcia of a muſcle, or the aponeuroſis of the foot, is ſoft and elaſtic, but in other caſes tenſe. It is at firſt free from uneaſineſs; but by degrees a ſharp acute pain darts occaſionally through it, more and more frequently, until the ſuffering is inceſſant. For a conſiderable time the tumour is ſmooth and even; but afterwards it projects irregularly in one or more points, and the ſkin at this place becomes of a livid red colour, and feels thinner than elſewhere. It here readily yields to preſſure, but inſtantly bounds up again. Small openings now form in theſe projections, and diſcharge a thin bloody matter. Almoſt immediately after theſe tumours burſt, a ſmall fungus protrudes, like a papilla, rapidly increaſes both in breadth and height, aſſumes the appearance of a carcinomatous fungus, and often bleeds in a very profuſe manner. The matter is thin, and exceedingly fœtid, and the pain is ſaid to be of the ſmarting kind. The

integuments

integuments are red and tender for ſome extent round the ulcers. After ulceration has taken place, the neighbouring glands ſwell, and put on exactly the ſpongy qualities of the primary tumour. If the patient ſtill ſurvive this advanced ſtate of the diſtemper, ſimilar tumours form in other parts of the body, and the patient dies hectic. (Diſſertations on Inflammation, vol. ii. p. 303.)

According to a late practical writer, when the diſeaſe is limited to the adipoſe, or cellular membrane, which covers the muſcles, the tumour is not uſually painful in the beginning, nor does it impede the motion of the muſcles on which it is ſeated. But when the diſorder occupies a deeper ſituation in the limbs, pain and weakneſs of the affected parts are felt. The fungus, alſo, as it increaſes in bulk, does not render the integuments uniformly thin, as in the caſe of an abſceſs. In one part the tumour, when preſſed with the hands, will afford the ſenſation of a deep-ſeated fluid, while another part will feel hard and uneven. Mr. Hey differs a little from Mr. Burns, in ſtating that the ſkin does not become uniformly thin and of a red colour, as when purulent matter is making its way to the ſurface of the body; but, on the contrary, that the integuments continue to feel as thick as uſual round the fungus, which protrudes through them. (Practical Obſervations in Surgery, p. 283, 284).

Fungus hæmatodes is ſeen on the extremities in ſubjects of every age, although, as we have already explained, the ſame affection of the eye-ball is commonly met with in children under the age of twelve.

Sometimes the tumour has ſucceeded ſome external violence, and conſequently, at firſt, has not been diſtinguiſhable from the common ſwelling of the injured parts.

It is the nature of the tumour to grow in the commencement by ſlow degrees; but as ſoon as an opening is made, the fungus generally ſhoots up with aſtoniſhing quickneſs.

The tumour, before ulceration occurs, often preſents ſo deceitful a ſenſe of fluctuation as to induce very experienced ſurgeons to believe that the caſe is a collection of fluid, and, of courſe, to make a puncture with a lancet. This proceeding ſhould always be carefully avoided, ſince it never fails to aggravate the diſeaſe, and accelerate the patient's diſſolution.

The fungus which ariſes on the extremities is generally of a round form, has an unequal rugged ſurface, and clotted blood is frequently ſeen adhering to it. It is of a dark red colour, is eaſily torn, and bleeds on being touched even in a gentle way. Its neck is commonly very narrow, while the upper portion ſpreads out very much, ſo as completely to cover the edge of the ulcerated ſkin.

When the fungus has attained a large ſize, the moſt prominent portions ſlough away, attended with an exceedingly fœtid diſcharge, and conſiderable hemorrhage.

Sometimes the abſorbent glands become contaminated with the diſeaſe, while the ſwelling is yet ſmall, in other caſes not till it ulcerates. The glands between the tumour and the thoracic duct are thoſe which are liable to be affected, ſo that, when the fungus hæmatodes is on the lower extremity, the glands in the groin, and all thoſe in the courſe of the iliac veſſels and aorta, are apt to be diſeaſed.

When a fungus hæmatodes, ſituated on one of the limbs, is examined after death or amputation, the tumour itſelf is found to conſiſt of a ſoft ſubſtance, ſomewhat like the brain, of a greyiſh colour and greaſy appearance, with thin membranous-looking diviſions running through it, and cells or abſceſſes in different places, containing a thin bloody matter, occaſionally in very conſiderable quantity. There does not ſeem uniformly to be an entire cyſt ſurrounding the tumour; for the ſwelling very frequently dives down betwixt the muſcles, or down to the bone, to which it often appears to adhere. The neighbouring muſcles are of a pale colour, and loſe their fibrous appearance, becoming more like liver than muſcle. The bones in the vicinity of the tumour are always carious. (See Burns on Inflammation, vol. ii. p. 305.)

When the parts containing the fungus are divided, they are found to be in a morbid ſtate. The adipoſe membrane forms a great number of pouches, filled with the fungus, upon the removal of which the pouches, if the patient be alive, bleed profuſely from every part of their internal ſurface. (Hey's Practical Obſervations in Surgery, p. 284.)

We have remarked, that in fungus hæmatodes of the eye other parts of the body were often affected with the diſeaſe before the patient's death. So when the extremities are the ſeat of the diſtemper, the lymphatic glands in the courſe of abſorption are apt to become diſeaſed, and not only theſe parts are ſometimes found in a morbid ſtate, but even the brain, the kidney, the liver, the breaſt, and other viſcera, as ſeveral well-authenticated caſes have now indiſputably proved. The reader may, if he pleaſe, be convinced of this important fact by referring to ſome of the examples which are detailed in Mr. Wardrop's late publication.

We have ſtated, that Mr. Burns of Glaſgow firſt wrote upon the fungus hæmatodes, as a diſtinct and peculiar diſeaſe, under the name of "ſpongoid inflammation." There are, however, numerous caſes of the diſeaſe recorded in ſurgical books by authors who were unacquainted with the general character of the complaint. See "An account of an anomalous tumour of the leg unſucceſsfully treated," publiſhed in Monro's works. Likewiſe the deſcription, which Mr. Pott has given, of a peculiar ſwelling of the calf of the leg, in his remarks on amputation.

On the ſubject of the treatment of fungus hæmatodes, ſituated on the extremities, we need not long detain the reader. When he hears that no internal medicine, nor external application, ſeems to have the leaſt power of checking this malignant diſeaſe, he will naturally turn his mind to the plan of extirpation with the knife. Mr. Hey informs us, that the growth of the fungus cannot always be repreſſed by the ſtrongeſt eſcharotics. Neither the hydrargyrus nitratus ruber, the hydrargyrus muriatus, the antimonium muriatum, nor the undiluted vitriolic acid, has been ſufficient for this purpoſe, and ſurgeons may always be certain, that when they irritate any malignant diſeaſe by plans which fail in accompliſhing its extirpation, they inevitably accelerate the expanſion of the morbid ravages, and haſten the patient's death.

The fungus hæmatodes is one of thoſe terrible maladies with which no wiſe ſurgeon will dare to tamper. As ſoon as the nature of the caſe is aſcertained, the whole of the diſeaſed ſubſtance, and parts in its vicinity, ſhould be carefully cut away. We are of opinion, that if this plan be ſtrictly executed, the patient will have as much chance of recovery, as if the limb were amputated. It is our duty, however, to ſtate, that in all the caſes in which the tumour alone was extirpated by Monro, Burns, and Hey, the diſeaſe recurred. Hence, Mr. Wardrop thinks, that we are warranted in urging the removal of the whole limb, as ſoon as the true nature of the caſe is manifeſt. When therefore any tumour is ſuſpected of being a fungus hæmatodes, the latter gentleman ſuggeſts the plan of making an opening into the ſwelling, for the purpoſe of ſeeing its ſtructure, and thus forming a deciſive judgment. If the caſe prove to be fungus hæmatodes, the limb might be immediately

mediately removed; if not, the ſurgeon might be content with putting in practice whatever meaſures the particular nature of the caſe ſhould require.

There are a few circumſtances which are quite manifeſt after the foregoing account. Firſt, that if an attempt be made to cut away the tumour, and ſave the limb, the ſurgeon muſt take care to remove at the ſame time a conſiderable quantity of the ſoft parts in the circumference of the ſwelling. Secondly, that after the tumour is taken out, a careful examination of the ſurface of the wound ſhould be made, and every ſuſpicious part or fibre cut away. Thirdly, that ſhould the diſeaſe, notwithſtanding ſuch caution recur, amputation ſhould be performed without delay. Fourthly, that cauſtics ſhould never be employed in theſe caſes. Laſtly, that as other inviſible parts and viſcera are often diſeaſed at the time when the operation is done, the ſurgeon ſhould always be upon his guard, and not raiſe the hopes of the patient's friends too high. Were he to act otherwiſe, reproach and loſs of reputation would be the frequent conſequences of his conduct.

The teſticle is liable to the fungus hæmatodes, and the affection was firſt deſcribed by Dr. Baillie, in his Morbid Anatomy, under the name of the *pulpy teſticle*. Mr. Abernethy, in his publication on tumours, has given an account of what he terms *medullary ſarcoma*, and of a remarkable inſtance, in which the foregoing part was attacked. It is ſuppoſed, that the medullary ſarcoma of Mr. Abernethy is, in reality, the ſame as the fungus hæmatodes of Hey, Wardrop, and other writers. The caſe to which we have alluded being very illuſtrative of the nature of this diſeaſe in the teſticle, we conceive that the reader will not regret its inſertion in the preſent article.

"A tall, thin, healthy-looking man, of about forty years of age, had, about fifteen years before, a ſwelled teſticle from a gonorrhœa; the epididymis remained indurated. Six years afterwards it became enlarged, and a hydrocele at the ſame time formed. Half a pint of water was diſcharged by a puncture, but inflammation ſucceeded the operation, and this teſtis became very large. An abſceſs formed, and burſt in the front of the ſcrotum, and the teſtis ſubſided in ſome degree. Mercury was employed to reduce it, but without effect. The part, however, was indolent, and gave the patient no trouble but from its bulk.

"About a year afterwards, a gland enlarged in the left groin (the ſame ſide as the teſtis): another then became ſwoln in the right groin, and, in the courſe of two years, ſeveral glands in each groin had obtained a very conſiderable magnitude. At this period, he was admitted into St. Bartholomew's Hoſpital under the care of Mr. Long. The teſtis was, at this time, between four or five inches in length, and about three in breadth; it reſembled its natural form, and was indolent in its diſpoſition. The ſpermatic chord was thickened, but not much indurated. Four or five glands were enlarged in the groin on both ſides; each of which was of the ſize of a very large orange; and, when obſerved together, they formed a tumour of very uncommon ſhape and magnitude.

"They gradually increaſed in ſize for ſeveral months, till at laſt the ſkin appeared as if unable to contain them any longer. It became thin, inflamed, and ulcerated, firſt in the left groin, and thus expoſed one of the moſt prominent tumours. The expoſed tumour inflamed and ſloughed progreſſively, till it entirely came away. As the ſloughing expoſed its veſſels, which were large, they bled profuſely, inſomuch that the ſtudents endeavoured, but in vain, to ſecure them by ligatures; for the ſubſtance of the tumour was cut through, and torn away in the attempt. Preſſure by the finger, continued for ſome time, was the only effectual mode of reſtraining this hemorrhage.

"The loſs of one gland relieved the diſtended ſkin, which had only ulcerated on the moſt prominent part of the tumour, and had not become diſeaſed. It now loſt its inflamed aſpect: granulations formed, and a cicatrix took place. In the oppoſite groin a ſimilar occurrence happened. One gland, expoſed by the ulceration of the ſkin, ſloughed out, being attended by the circumſtances juſt recited. However, before the ſkin was cicatrized, ulceration had again taken place in the right groin, in conſequence of the great diſtenſion of the ſkin from the growth of the tumour; and ſloughing had begun in the tumour, when the patient, whoſe vital powers had long been greatly exhauſted, died." See Surgical Obſervations, &c. 1804, by J. Abernethy, F. R. S. &c.)

In this example, the diſeaſe extended to many parts beſides the teſtis. The tumour, formed by the inguinal glands on each ſide, was as large as a man's head, and ſimilar in ſtructure to the diſeaſed teſticle. The pelvis was almoſt filled with ſimilarly diſeaſed glands, and the vertebræ were hidden by others as high up as the diaphragm. Some of them, upon being cut into, diſcharged a thick fluid reſembling cream.

Fungus hæmatodes of the teſticle is ſaid to begin, ſometimes in the body of that organ, ſometimes in the epididymis. The progreſs of the diſeaſe is ſlow, and the pain attending it is, in general, not great enough to excite alarm. Nor is there, at firſt, any inequality or hardneſs in the gland, nor change in the ſcrotum. When the teſticle has become exceedingly large, it feels remarkably ſoft and elaſtic, and as if it contained a fluid. Hence, the caſe has often been miſtaken for a hydrocele, and a puncture made with a trocar. Sometimes the tumour, when large, is in ſome places hard; in others ſoft. The hydrocele may be known by the water beginning to collect at the bottom of the ſcrotum, and then aſcending towards the ſpermatic cord, and by the ſwelling being circumſcribed towards the abdominal ring; whereas, in the fungus hæmatodes, the diſeaſe begins with a gradual enlargement of the teſticle itſelf, followed by a fullneſs, which extends up the ſpermatic cord. See Wardrop, p. 127.

It appears that the fungus hæmatodes in the teſticle does not claim this appellation, ſince, how large ſoever the tumour may be, it emits no fungous growth. Abſceſſes form, and the integuments of the ſcrotum burſt; but no fungus ſhoots out.

The teſtis is ſaid to be more frequently affected with the malady in young, than old perſons.

On diſſection, the ſubſtance of the diſeaſed teſticle is found to preſent a medullary, or pulpy appearance, generally of a pale browniſh colour, but ſometimes of a red. The conſiſtence is ſometimes uniform; ſometimes variegated, and interſected by thin membranes. When immerſed in water, a good deal of the medullary matter mixes with the fluid. In moſt caſes, the tunica albuginea and tunica vaginalis are adherent together: ſometimes there is a fluid between them. See Wardrop, 131—133.

With regard to the treatment, we have nothing to recommend, except caſtration, which, unleſs performed at an early period, before the diſeaſe extends up the cord, and to the lymphatic glands, muſt be unavailing. We fear, alſo, that the little alarm excited at firſt, and the difficulty of aſcertaining the early exiſtence of the diſeaſe, will always be ſtrong reaſons why few patients will ever be adviſed, or willing, to ſubmit to a timely operation. Its

reſult,

reſult, likewiſe, even when done early, muſt always be very uncertain, ſince moſt of the attempts to extirpate fungus hæmatodes in other ſituations have for the moſt part proved unſucceſsful, in conſequence of the diſeaſe recurring in a more malignant and fatal form.

Mr. Hey, in his "Practical Obſervations in Surgery," has related ſeveral caſes in which the female breaſt is ſtated to have been the ſeat of the fungus hæmatodes. Mr. Wardrop has expreſſed doubts about the reality of the diſtemper in the inſtances adduced by the foregoing writer. However, we are inclined to think, that the diſeaſe was fungus hæmatodes, ſomewhat diverſified from the common character of the complaint, by reaſon of the difference of ſtructure in which it was ſituated. Thus, in the teſticle, the diſtemper has its peculiarities, ſince, in this organ, when the integuments burſt, no fungus ſhoots out; and yet Mr. Wardrop does not heſitate to admit ſuch diſeaſe to be the formidable diſorder of which we have now been treating.

The following are ſome of the moſt remarkable circumſtances which occurred in one example recorded by Mr. Hey. In making an exertion, a maiden lady, aged 54, felt ſomething crack in her breaſt. A few days afterwards, a ſmall tumour, about the ſize of a hazel-nut, took place in the part. The ſwelling got gradually larger, was hard, and moveable. At length, it extended nearly to the axilla on one ſide, and the ſternum on the other. Its ſurface was uneven, and the integuments were in ſome places thick. At other parts they were thin, and felt as if a fluid were under them. When the harder parts were handled, Mr. Hey had a ſenſation as if he had broken ſome fibrous ſubſtance. Shooting pains had been felt in the tumour from its commencement.

The ſkin at laſt gave way; a dark-coloured ſubſtance aroſe in the fiſſure; and blood began to ooze out of the opening. This aperture afterwards became ſo large, that much bleeding uſed to take place from it, whenever the hemorrhage was not ſtopped by a coagulum.

Mr. Hey removed a large oval piece of the diſeaſed integuments, chiefly with a view of ſuppreſſing the bleeding, with ſtyptics.

The fungous ſubſtance, making the greater part of the tumour, bore a reſemblance to that of a fungus hæmatodes of the thigh, recorded by the ſame writer, p. 233. The maſs, upon being broken, bled. It adhered ſtrongly to the remaining part of the integuments, which formed a great number of irregular cells. Indeed, the whole internal ſurface of the ſac containing the fungus was compoſed of theſe cells, except the bottom, which was formed by the pectoral muſcle, and was more even. In the operation, a diſeaſed portion of this muſcle, about two inches ſquare, was left uncovered. It ſeemed as if it had been expoſed to the air, and had begun to form granulations. The muſcular fibres were ſcarcely diſtinguiſhable. The whole internal ſurface of the ſac bled, as if the blood had been ſqueezed from a ſponge. Ruſpini's ſtyptic was applied with lint to the muſcle, and hot oil of turpentine to the reſt of the cavity. The applications were kept on with a circular bandage.

The patient only lived till the morning of the day which followed the operation. It ſeems, that before ſhe died a good deal of blood had been loſt. See Practical Obſervations in Surgery, p. 254.

We need only add our own belief, that this caſe ſeems to merit the name of fungus hæmatodes, and that the only chance which the patient had of life depended upon the earlier attempt to cut away every particle of the diſeaſe. When this opportunity had paſſed away, perhaps it might have been moſt prudent not to have employed the knife at all, particularly as the only end of doing ſo ſeems to have been that of applying very irritating ſtyptic applications.

The reader is already appriſed, that the fungus hæmatodes has generally been confounded with carcinomatous affections. Hence, it ſeems proper, before taking our leave of this ſubject, to notice the principal differences between cancer and fungus hæmatodes. This taſk ſeems yet neceſſary; for, notwithſtanding the two caſes may be eaſily diſcriminated by certain peculiarities, it is acknowledged, that in ſome circumſtances there exiſts an analogy. Thus the progreſs of the two diſeaſes, eſpecially in the early ſtage, is generally ſlow. When ulceration happens, a thin fœtid ichor is diſcharged, inſtead of purulent matter, and, occaſionally, both maladies are attended with profuſe hemorrhages. Both diſeaſes often emit a fungus; both contaminate the lymphatic glands in the direction of the abſorption; and both are apt to involve in the morbid ravages every kind of ſtructure which may happen to be near. Laſtly, both diſeaſes frequently affect at once ſeveral parts of the body. All theſe circumſtances have been noticed by Mr. Wardrop.

The ſame gentleman has explained, that a ſchirrous tumour is, from its commencement, hard, firm, and incompreſſible, and is compoſed of two ſubſtances; one hardened and fibrous; the other ſoft and inorganic. The fibrous mattter is the moſt abundant, conſiſting of ſepta, which are paler than the ſoft ſubſtance between them. The ſoft matter is ſometimes ſemi-tranſparent, and of a blueiſh colour, differing ſomewhat, however, in its appearances in different caſes.

A ſchirrous tumour, ſituated in the gland, is not capable of being ſeparated from the latter part, ſo much are the two ſtructures blended. A ſcirrhus in another ſituation ſometimes condenſes the ſurrounding cellular ſubſtance, ſo as to form a kind of capſule, and aſſume a circumſcribed appearance.

When a ſcirrhous ſwelling ulcerates, a thin ichor is diſcharged, and a good deal of the hard fibrous ſubſtance is deſtroyed by the ulceration, and the tumour is leſſened. The diſeaſe continues to ſpread by ulceration, other parts become affected, and the patient dies from the increaſed quantity of morbid ravages and the irritation on the conſtitution.

Sometimes, though not always, after a ſcirrhus has ulcerated, it emits a fungus of a very hard texture. Such excreſcence, however, is itſelf at laſt deſtroyed by the ulceration. It is curious alſo, that cancerous ſores often put on, for a ſhort time, at a particular part, an appearance of cicatrization.

On the other hand, as Mr. Wardrop has remarked, the fungus hæmatodes, while of moderate ſize, is a ſoft, elaſtic ſwelling, with an equal ſurface, and a falſe feel of a fluctuation. It is in general quite circumſcribed, being contained in a perfect capſule. The ſubſtance of the tumour, inſtead of being for the moſt part hard, conſiſts of a ſoft, pulpy, medullary matter, which readily mixes with water. When ulceration occurs, the tumour is not leſſened by this proceſs, as in ſcirrhus, but a fungus is emitted, and the whole ſwelling ſeems to grow with increaſed rapidity.

Finally, we ſhall obſerve, that cancerous diſeaſes are moſt frequently met with in perſons who are conſiderably advanced in life; that fungus hæmatodes generally afflicts young ſubjects; and that the latter diſtemper has been obſerved in the liver, ſpleen, kidney, and lungs, parts in which true cancer has never yet been remarked. Such readers as deſire to be particularly acquainted with the ſubject of fungus hæmatodes, may learn all that is yet known con-

concerning this formidable diſeaſe, by referring to the ſecond volume of ſome "Diſſertations on Inflammation," by John Burns, (ſee page 302, on Spongoid Inflammation); and conſulting Hey's "Practical Obſervations in Surgery," p. 233; Abernethy's "Surgical Obſervations," publiſhed 1804, p. 51; and, in particular, "Obſervations on Fungus Hæmatodes," by James Wardrop, printed 1809.

FUNGUS *Oculi*, in *Veterinary Science*, a name given by ſome of the writers on the diſeaſes of horſes to a diſtemper of the eye, to which that animal alone is ſubject. The firſt author who has communicated an obſervation of this diſorder to the world is Dr. Lower, in the Philoſophical Tranſactions. He obſerves, that horſes alone are ſubject to it, and calls it a ſpungy excreſcence of the uvea; it is commonly of a dark muſk-colour, and grows out of the edge of the uvea, and though of little conſequence in its firſt ſtages, yet if it grows very large, or if the number of the funguſes increaſe, it weakens and obſtructs the creature's ſight, and ſometimes wholly takes it away. The uvea is a muſcular part, and its chief uſe is to dilate or contract itſelf in a proper manner for the admiſſion of objects with as much light as the eye can bear, ſo that the brighter the light is to which the eye is expoſed, the more this membrane is contracted into a narrow compaſs, and the more dark the place is, the more the opening is dilated. This ſudden change, and the office of this part, may be more conveniently ſeen in the eye of a cat, than in that of any other animal, but it is the ſame in all, in a greater or leſs degree. If the edge of this coat be loaded with a very large excreſcence of this kind, or if ſeveral, though ſmaller, grow all round it, it muſt neceſſarily happen, that the pupil, or ſight, is very much if not totally obſtructed, and the animal ſees very little, or not at all. The horſes of this kind are very ill furniſhed for ſeeing in the ſunſhine, but do very well in dark days, or in the duſk of the morning or evening, when the diſeaſe is not too violent. It is obſervable, that when theſe funguſes grow in the eyes of young horſes, they become much ſmaller when they are taken to dry meat in the ſtable, and increaſe again when they are turned out to graſs. Whether this be owing to the difference of dry and moiſt food is not eaſy to determine, but it is moſt probably owing to the difference of paſture; the horſe at graſs, being obliged to carry its head much lower than thoſe which feed in the ſtable. Thoſe funguſes that are fixed on the upper part of the uvea are apt to grow the largeſt, and to hinder the ſight moſt; and thoſe which grow in the middle of the uvea hinder the ſight more by diſtracting the object than thoſe which grow in either corner or angle of it. The cure is not eaſy; all that can be attempted muſt be by dry diet, and attenuating medicines; and a palliative remedy may be the hanging ſomething over to ſhade the eye, and keeping it from being expoſed nakedly to the ſun, the conſequence of which will be, that the pupil will not be ſo cloſely contracted, and conſequently the light not ſo much obſtructed. Phil. Tranſ. N° 32.

FUNIKEDY, in *Geography*, a town of Africa, in Kaarta; 36 miles N. of Kemmoo.

FUNIS, or FUNICULUS, *Umbilicalis*, in *Anatomy*, the umbilical chord, which conſiſts of two arteries and a vein, named umbilical, which have the office of keeping up the communication between the circulating organs of the fœtus and the placenta; convoluted on each other, and ſurrounded by a quantity of gelatinous ſubſtance. See EMBRYO.

FUNIS *Umbilicalis, Preſentation of*, in *Midwifery*, is when in labour the navel ſtring deſcends into the vagina, before the preſenting part of the child. It ſometimes happens, that on the burſting of the membranes in the courſe of a labour, and the ruſhing forth of the waters, the funis umbilicalis, or navel-ſtring, comes down, with or before the preſenting part of the fœtus. This rarely happens in a natural labour, or when the breech of the fœtus lies over the os uteri, as the head or breech, by their ſize and adaptation to the ſhape of the brim of the pelvis, generally prevent any other body from entering the paſſage with them. When, however, the funis is of an extraordinary length, it will ſometimes enter the pelvis before the head or breech of the child, and conſequently precede them. If this caſe be neglected, and the labour ſuffered to go on, the funis will be gradually thruſt down by the pains, until it frees the external orifice of the vagina, and becoming cold, the blood in the veſſels will be congealed, the circulation ſtopped, and the life of the child extinguiſhed. To prevent this accident, authors have recommended carrying the funis up into the uterus with the hand, beyond the preſenting part, and detaining it there, until ſome part of the child enters, and fills up the brim of the pelvis. To do this the more effectually, we are told to incloſe the pendent part of the funis in a linen rag, or in a bag made of ſoft leather. But theſe methods, Dr. Denman rightly obſerves, have rarely been found to ſucceed, (ſee his Introduction to the Practice of Midwifery, 4to. p. 559,) the funis generally following the hand, when it is withdrawn, or coming down with the following pains. If we are called in late, and the funis has been down ſo long that the life of the child is deſtroyed, or if the child was dead before the commencement of labour, (and in either caſe we may know that to have happened, from the total want of pulſation in the funis,) the labour may then be conducted in the ſame manner as if the funis had not preſented, as it will not occaſion any impediment to the birth. That is, if the head, feet, or breech prove either of them to be the part preſenting, the woman is to be encouraged, and the child ſuffered to come into the world in the way it offers, giving only the aſſiſtance directed under the articles *Natural* LABOUR, BREECH, or FEET *preſentations*, which ſee. We ſhould be particularly careful, in this caſe, to conceal from the mother the death of the child, the knowledge of which, by diſpiriting her, might damp, or even put a total ſtop to the pains, and thence materially retard the labour, or in delicate habits, occaſion flooding, or convulſions. On the other hand, if from perceiving a pulſation in the funis we are ſatisfied the child is alive, inſtead of making futile and unavailing attempts to return the funis, if the os uteri is ſufficiently dilated, or is ſo ſoft and yielding as to admit it, we muſt paſs a hand leiſurely and ſlowly into the uterus, whatever may be the preſenting part, and turn the child, and bring it by the feet. For the manner of doing this, ſee LABOUR, *Preternatural*. But if the head of the child be too far advanced in the pelvis, before we are called, to make this practicable, or ſafe, we muſt content ourſelves with keeping the funis in the vagina, to prevent its contracting cold, and as far out of the way of preſſure as we can, and leave the excluſion of the child to the pains; or if the pains ſhould be ſlow and feeble, and the head of the child, after deſcending ſo low as to preſs upon the external orifice, ſhould remain there, little moved by the pains, we may aſſiſt them, and accelerate the birth by uſing the lever, or the forceps. The lever, perhaps, will, generally ſpeaking, be moſt adviſeable in this caſe, as leſs likely to preſs or injure the funis, more eaſy in its application, and more ſpeedy in producing the deſired effect.

FUNIS *Crepitans*. See CISSUS.

FUNK ISLAND, in *Geography*, a ſmall iſland in the Atlantic, near the N.E. coaſt of Newfoundland. N. lat. 50°. W. long. 52° 15'.

FUNKAKUN, a town of Perſia, in the province of Mazanderan; 15 miles W. of Fehrabat.

FUNKS TOWN. See JERUSALEM.

FUNNEL *of a Chimney*, the ſhaft or ſmalleſt part of the chimney from the waiſt upwards. Palladio orders, that the funnel be raiſed three, four, or five feet at leaſt, above the roof, that it may carry the ſmoke clear from the houſe into the air.

Care, too, is to be taken as to the width; becauſe, if it be too wide, the wind will drive back the ſmoke into the room: and if too narrow, the ſmoke will not be able to make its way. Chamber chimneys, therefore, are not to be made narrower than ten or eleven inches; nor broader than fifteen. See CHIMNEY and FLUE.

FUNNEL, in *Engineery*, ſignifies the ſame with culvert, or drain.

FUNNEL, in *Chemiſtry*, &c. a well known inſtrument uſed in decanting and filtering liquors, and made either of glaſs or pewter or tin, or tinned iron, or earthen ware. Some are *ribbed*, in order to ſupport large paper filters; and the funnel, called *ſeparatory*, is intended for the ſeparation of liquids of different ſpecific gravity, by allowing the heavieſt only to drop out of the narrow part of the inſtrument.

FUNNEL *Polype*. See POLYPE.

FUNNEL-*ſhaped Hollows*, in *Geology*, is a phenomenon which Mr. Jameſon has obſerved, (Geognoſy, p. 34. 172.) in gypſeous diſtricts; and we have obſerved ſimilar dimples, or depreſſions, in the chalk ſtrata about Fakenham in Norfolk, and other places, ſeemingly occaſioned by the gradual breaking in of the ſuperficial ſtrata, into cavities in thoſe beneath; as we judge from the ſimilarity of theſe funnel-ſhaped hollows to old ſhafts which have in the miners' phraſe *run-in*.

FUORTI, in *Geography*, a town of Naples, in Abruzzo Citra; 21 miles S.S.E. of Salmona.

FU-RAN. See EPIDENDRUM.

FUR. See DARFUR.

FUR, in *Commerce*, is a general term, comprifing the ſkins of different kinds of wild animals, that are found in high northern latitudes, particularly thoſe forming part of the American continent; ſuch as the beaver, bear, mooſe-deer, marten, mink, woolverin, wolf, &c. &c. &c. When theſe ſkins are in an unimproved ſtate, as they come from the hands of the Indian hunters, they properly claſs under the denomination of *peltry*; but when they have had the inner ſide converted into leather, by an aluminous proceſs, they then aſſume the appellation of furs; and the art of thus manufacturing them is called *furriery*.

FURS, or *Furrs*, is a term, in its confined ſenſe, applied to the ſkins of different hairy quadrupeds, when they have undergone an aluminous proceſs, by which the inſide integuments are converted into a kind of coriaceous ſubſtance. In this view *furs* differ from *peltries*, which are the ſame ſkins in the ſtate they are taken from the animals, and ſimply dried, or in a ſtricter meaning of the word, the latter only compriſes ſkins covered with ſhorthair, as the deer, elk, buffaloe, &c., principally manufactured into leather. But in a general ſenſe, the term fur includes all kinds of ſkins which are uſed in furriery, *viz.* bear, beaver, mink, marten, otter, fox, ermine, ſable, ſquirrel, cat, hare, rabbit, &c. Reſpecting the relative eſtimation of the various kinds much appears to depend upon the ſeveral uſes to which they are generally applied; and their intrinſic value upon the climate, whence they are brought, the age or health of the animals, and the ſeaſon of the year when caught and killed. It has been frequently remarked by natural hiſtorians, that the colder the country, the larger and warmer is the fur of each animal; it being wiſely provided in the economy of nature, that the clothing of the inhabitant ſhould be adapted to the rigours of his ſituation. Thus the fox and wolf, which in temperate climates have but comparatively ſhort hair, in the frozen regions near the pole are covered with a fine long and thick fur. The beaver and the ermine, which are found in the greateſt plenty in high northern latitudes, are remarkable for the warmth and delicacy of their furs. It is not an eaſy taſk to account for this remarkable warmth of furs in northern quadrupeds. Some have ſuppoſed it originates in ſpare and ſcanty diet, with the difficulty of obtaining food, to which animals in ſuch climates are ſubjected. Others, with more probability, have aſcribed it to the ſeverity of the cold, contracting the pores of the ſkin, ſo that the hair conſequently takes the ſhape or ſize of the orifice through which it grows; as wires are made ſmaller and longer by being drawn through narrower apertures. From whatever cauſe it may ariſe, ſuch is the fact; and farther, all the animals of the arctic climates may be ſaid to have their winter and ſummer garments, except very far to the north, where the cold is ſo continually intenſe, that, according to Crantz, no change of colour is perceivable either in the fox or bear. Hence it is, that the furs of high northern latitudes are better in quality than thoſe of more temperate climes; the produce of Siberia ſuperior to thoſe of Ruſſia; and the imports from Canada preferable to thoſe from the United States. This fact alſo accounts for the difference of value in ſimilar articles brought from the ſame country; for during winter the furs of moſt animals improve both in quality and colour. Indeed ſome kinds, as thoſe of the iſatis or croſs fox, unleſs killed at that ſeaſon, are in no eſtimation.

Of the leaſt valuable among the kinds of furs, thoſe of the rabbit and hare may be claſſed, although they are more generally known from the circumſtance of their forming a conſiderable article in the hat manufacture; for which purpoſe vaſt quantities are imported from thoſe countries bordering on the polar regions, where they are found as white as the ſnow they traverſe, and in ſuch plenty, that they are ſold on the ſpot, or rather bartered for the value of five ſhillings per hundred. It is not eaſy to aſcertain the exact time when furs were firſt uſed in the hat trade. The ſtipulations for the preſervation of rabbits in different treaties reſpecting Calais, ſigned between the Engliſh and French, previouſly to the year 1440, have induced ſome writers to ſuppoſe the improvement was adopted about the beginning of the fifteenth century. But even in the time of Elizabeth the wearing of hats was reſtricted by act of parliament to the upper claſſes in ſociety; the middling and lower being confined, under forfeiture of a penalty, to the uſe of knit caps. This act, however, was ſoon after repealed, and the uſe of felt hats, and others manufactured from fur, came into general wear. In 1638, king Charles having incorporated the makers of theſe hats and caps into a privileged company, he affixed regulations for the trade, prohibited the importation of beaver hats, and reſtricted the hatters to the uſe of that article, allowing the admixture of other ſubſtances, only in hats and caps, called *demi-caſtors*, intended for importation. From this period may be dated the increaſe in the value of the beaver fur, which now ſupplies that manufacture with its moſt valuable commodity. Of beavers, the

ſkins of the middle-aged or the young, called cub-beaver, is the moſt valuable, the wool being the fineſt, moſt gloſſy, and ſuſceptible of the moſt permanent dye.

Fox ſkins furniſh a conſiderable variety of furs. In the cold countries animals of this ſpecies are of all colours, white, grey, blue, iron-grey, ſilver-grey, variegated and black. Of theſe, the laſt is the moſt valuable, and the firſt the leaſt. The hair of the white fox is very liable to fall off; the blue are ſought for with avidity, owing to their ſcarcity; and the black fetch a high price, from their juſtly acknowledged beauty. The generality of this kind of ſkins, like thoſe of the wolf and bear, are manufactured into muffs, tippets, cloaks, and other defenſative articles of winter dreſs.

The different ſpecies of animals which conſtitute the weaſel genus furniſh many of the fineſt and moſt generally eſteemed furs. The fur of the wild-cat is ſoft and warm, but from an offenſive ſmell, which it tenaciouſly retains, the value falls below that of others of a very inferior kind. The marten affords a ſkin of various colours, but the part of it held in the higheſt eſtimation is that browner than the reſt, extending along the ſpine. The ſkin of the ſable is highly coveted, which is in colour a browniſh black, and the darker the more deſirable it becomes. The fur of this animal is finer, ſofter, and more gloſſy than that of any other quadruped, except its equally eſtimable congener the ermine, which is the moſt valuable of any hitherto known. In ſummer the ermine is brown, and called the ſtoat. It is in winter only that this little animal has its fur of the proper colour and conſiſtence. At the approach of the inclement ſeaſon the hair, from being coarſe and ſhort, lengthens and grows finer, while numerous ſmaller hairs riſe up between the longer, thicken the coat, and give it all the warmth and ſoftneſs which is ſo much admired in the furs of northern animals, and ſets ſo high a price upon their ſkins. The ſnowy whiteneſs which the ermine's fur aſſumes at that time of the year confers on it alſo an additional value.

Many other animals afford furs of various qualities, which, according to their uſes, differ as to the degree of eſtimation in which they are held; as the woolverin, raccoon, muſquaſh, genet, and ſloth, the fur of which laſt poſſeſſes ſuch a beautiful luſtre as to give it the preference to that of all other animals, except the ermine, ſable, and Siberian fox. Another fur-bearing animal of the American continent, and lately diſcovered, muſt not paſs unnoticed, becauſe it is likely, at no diſtant period, greatly to enhance the importance of the trade in articles of this deſcription, the ſea-otter. This inhabitant of the New World furniſhes a complete rival to any in the Old; its fur being, in the opinion of experienced judges, the fineſt and moſt deſirable for many purpoſes of any yet produced in all parts of the globe. Captain Clarke, who ſucceeded captain Cook, collected a quantity in the vicinity of Nootka Sound, and carried them to China, where they ſold as high as one hundred dollars per ſkin. The account of this induced other adventurers to open a trade to Canton; but the Chineſe emperor, jealous of European communication, quickly prohibited this branch of commerce. The Columbia, Miſſouri, and other rivers, which riſing in the north-weſt parts of America, fall into the great Pacific ocean, are known to abound with ſea-otters; and theſe will probably ſoon furniſh a new ſource of profitable ſpeculation.

Fur *Trade*. The uſe of furs and peltry is nearly coeval with the hiſtory of man. From the primeval pair having been clad in veſtments of ſkins, the cuſtom of adopting ſuch a kind of dreſs was obviouſly deduced, and the multiplication, and ſubſequent diſperſion of mankind, for peopling the earth, would extend and perpetuate the uſage during the firſt ſtages of civilization.

"——————————Cum frigida parvas
Præberet ſpelunca domos, ignemque Laremque,
Et pecus & dominos communi clauderet umbra:
Silveſtrem montana torum cum ſterneret uxor
Frondibus, & culmo vicinarumque ferarum
Pellibus."

Juvenal Sat. l. vi.

Accordingly, hiſtorians and poets deſcribe people in the ruder ages of the world, when hunting and fighting appear to have been their principal employment, as uſually clothed in this manner: and the cuſtom would prevail till art had taught the ſuperior advantages of wool, and invention afforded her aſſiſtance in its multifarious fabrication. Thus Virgil, when he deſcribes Æneas about to take his departure from Troy, repreſents him as having his outer veſt formed of a lion's ſkin.

"Hæc fatus, lateros humeros ſubjectaque colla
Veſte ſuper fulvique inſternor *pelle* leonis."

Æneid, lib. ii.

In book the fifth, he depicts Aceſtes as formidably clad in the ſkin of a Libyan bear.

In the various iſlands and countries lately brought to our knowledge by numerous voyages of diſcovery, and where the arts appear in a ſtate of infancy, the uſage of wearing furs and ſkins is ſtill prevalent among the natives; from the northern point of Kamtſchatka to the moſt ſoutherly iſlands in the Pacific ocean, from the ſeats of the Nathana and Quarrelling Indians to the great wall which ſeparates China from the Siberian deſarts. As tribes multiplied, cultivation increaſed, and conſequently woods diminiſhed, the haunts of undomeſticated animals would become more diſtant from the habitations of man; hunting and killing them would thus become more toilſome, which muſt neceſſarily enhance the value of ſkins, and what originally were conſidered as cheap and common neceſſaries, would at length be claſſed among the more valuable and coſtly commodities. In the ſacred book of Exodus, among the offerings made towards erecting the tabernacle for Jehovah, are enumerated purple, ſcarlet, and fine linen, with goat-ſkins, red ſkins of rams, and badger ſkins. The ſacred book of Numbers, which contains precepts for purification, provides that every thing made of ſkins, and all goods manufactured from goats' hair, were in a particular manner to be purged; becauſe they were calculated to retain longer the principles of contagion. From which paſſages it appears, that ſkins were not only uſed for furniſhing ſome portions of dreſs; but were alſo conſidered of great value long ſubſequent to the time when the arts of weaving and dyeing were diſcovered.

At what period, or among what people, furs became an article of luxury, is a ſubject on which little can be collected for elucidation. They do not appear to have conſtituted any part of dreſs worn by the patrician orders in the enlightened nations of Greece and Rome. Their uſe was probably confined to the northern parts of Aſia and Europe; and the cuſtom afterwards might have been extended to the middle and ſouthern parts of the latter continent, by thoſe immenſe hordes, which deſcended and deluged the Roman empire like a flood, the Goths and Vandals.

The hiſtory of various nations tends to ſhew that furs were anciently uſed to ornament the robes of princes, grandees, and perſons delegated with high authority. Veſtiges of their uſe in theſe reſpects are ſtill viſible in England, in the ſtate robes of the king, the nobility, judges, and other perſons

ſons of diſtinction, and in the public dreſſes of the chief magiſtrates, and officers in municipal corporate bodies. Their uſe is diſtinctly traceable in the bordering, impaling, quartering, and divers forms belonging to emblazonry in armorial bearings; where vair and ermine ſtill hold a conſpicuous rank. All which demonſtrate the prevalence of the cuſtom of furred garments in ages far remote from the preſent.

Of the fur trade at an early period, little has been recorded, though it certainly muſt have formed a conſiderable branch of commerce. There exiſted ſeveral reaſons why little has been detailed on this ſubject, as to the nature, extent, or mode in which the merchandize in furs and peltry was conducted. Previouſly to the diſcovery of the New World by Columbus, the furs, in general demand for Europe, were procured from the north and north-eaſtern parts of the Ruſſian empire. The diſcovery and annexation of the extenſive territory of Siberia in the ſixteenth century added greatly to the wealth and power of Ruſſia, by the numerous fiſheries, iron works, and particularly by the extenſive field it opened for the trade in furs. But previouſly to the direct communication with that empire by the Ruſſian company, formed under the auſpices of the celebrated Sebaſtian Cabot, and the diſcovery of the port of Archangel by captain Richard Chandler, the fur trade in the north-eaſt had been carried on through the ports of Livonia, lately poſſeſſed by the Teutonic knights of St. Mary of Jeruſalem, a republic, of which the Hanſeatic towns not along ago were the only remaining part; the Ruſſians, anterior to that period, not poſſeſſing any ſea-ports or ſhipping on the ſhores of the Ba'tic. Thus the articles, which conſtituted this department of commerce, found their way to a market by the interior of the north of Europe. In conſequence of this circuitous conveyance, the deſpotic nature of the Ruſſian monarchs, and the narrow policy adopted by that government, it was ſcarcely known for a long period from what particular places, or by what mode of intercourſe the furs and ſkins were procured. But the Livonian war having greatly injured the trade, the czar was induced to accede to the requeſt of the Engliſh merchants for permiſſion to trade directly to the Ruſſian coaſt.

The diſcovery and colonization of America, particularly the northern parts of it, bordering on the gulf of St. Lawrence and Hudſon's bay, gave a new turn to mercantile ſpeculations in furs and peltry.

Hudſon's bay was diſcovered by ſir Thomas Burton, and further ſurveyed in queſt of a north-weſt paſſage during the reign of Charles the Firſt, by captain Luke Fox. Afterwards prince Rupert, and ſeveral noble aſſociates, having ſent out captain Newland, on an exploratory voyage to the bay, and finding by the narrative of his proceedings that an advantageous commerce might be carried on with that part of the American continent, they determined to form an united company for the purpoſe of opening a new ſource of trade and wealth. In this purſuit they were encouraged by the return and ſucceſsful adventure of captain Gillam, who about the ſame period had been diſpatched on a trading voyage by ſome merchants of Briſtol. An application to the crown obtained for the aſſociation a charter for the excluſive right to attempt the diſcovery of a north-weſt paſſage, to proceed in that direction on mining inveſtigations, and to open with the natives of the Terra Incognita a trade in furs. By this charter, dated May 2, 1670, they were incorporated under the title of the governor and company of adventurers of England, trading to Hudſon's bay, with the ſole and excluſive privilege of navigating in all ſeas, bays, ſtraits, creeks, lakes, rivers, ſounds, &c. that lie within the entrance of the ſtraits, commonly called "Hudſon's ſtraits." This charter was a very ample one, and for a time had a moſt diſaſtrouſly excluſive effect upon the trade in furs. But ſuch charters, happily for commerce, were greatly abridged of their extenſive privileges, by one of thoſe eminent bulwarks of Engliſh liberty, which have at ſeveral important epochs diſtinguiſhed the conſtitution of Britain. By a ſtatute, enacted in the firſt year of king William and queen Mary, entitled "An act for declaring the rights and liberties of the ſubject, and ſettling the ſucceſſion of the crown," the privileges of the company, like every other not ſanctioned by an act of the legiſlature, were diſannulled, and though they ſtill pretend to poſſeſs prohibitory powers, every Britiſh ſubject has an equal right to participate in the trade to that quarter. Their firſt factory, fort, or eſtabliſhment on Nelſon river, was formed in the year 1682, and a Mr. John Bridgar was made governor. Soon after they ſet up others in different parts of the bay; but the French, who were jealous of the interference with the Indians, in the vicinity of their Canadian ſettlements, ſeized upon the forts, and diſpoſſeſſed the ſettlers. On application to the French court reſpecting this outrage, it was deemed a piratical act, and the king of France, as an indemnity, gave the company the French fort and factory on the river Hayes. Although the French in Canada did not at firſt pretend to a property in the countries about Hudſon's bay, yet in a few years after the company was eſtabliſhed, ſo early as 1674, their jealouſy of the Engliſh enterprize was very manifeſt. They became exceedingly troubleſome to the outpoſts, and erected a fort within eight days journey of the ſettlement on prince Rupert's river. They alſo endeavoured, by underſelling us in their barter with the Indians, to ruin our trade and intereſt with thoſe ſavages, which they were enabled effectually to do by their contiguity; the neareſt parts of Canada not being diſtant more than 150 miles from the above mentioned factory at fort Nelſon.

From this period, till the year 1714, the company's people were frequently annoyed and haraſſed by their litigious and ambitious neighbours; till, by the treaty of Utrecht, lines of demarcation were drawn between the two countries, and definitive articles agreed upon relative to the trade. After this they extended their concerns, and erected new ſettlements. In 1730 they poſſeſſed five, *viz.* on Albany river, Hayes's iſland, Rupert's river, Port Nelſon, and New Severn. The country about Hudſon's bay is very inhoſpitable and unfriendly to vegetable productions; for even in the ſouthern part, in the latitude of 51 degrees, it is exceſſively cold nine months in the year. In ſo wretched a country, therefore, there can be no plantations, properly ſo called, nor any towns and villages. The reſident traders therefore muſt be ſupplied with bread, beef, pork, flour, peas, and other neceſſaries from England, or ſome parts of America. With the poor ſavages of the country, commerce can be conducted by no other means than *barter;* and the beaver is made the medium, or agio, of exchange. Thus, for inſtance, the company for one beaver's ſkin, at one period, gave half a pound of gunpowder, four pound weight of lead ſhot, two hatchets, half a pound of glaſs-beads, one pound weight of tobacco, eight ſmall, or ſix large knives, one large and two ſmall powder horns. For 12 good winter-beaver ſkins, a gun of the beſt ſort; for eight do. the ſmalleſt ſized gun; for ſix do. a good laced coat; for five do. a plain red coat; for four do. a woman's coat; and ſo proportionably for kettles, looking-glaſſes, combs, &c. Arthur Dobbes, eſq. who publiſhed, in 1743, an account of Hudſon's bay, furniſhes this ratio of exchange between the company's agents and the Indians. A beaver ſkin, he ſays, as the medium of circulation, is the eſtabliſhed price of the

undermentioned articles, *viz.* a pound weight of braſs kettles, one and a half pound of gunpowder; five pounds of lead ſhot, ſix pounds of Brazil tobacco; one yard of bays, two combs; two yards of gartering, one pair of breeches, one piſtol, or two hatchets. Other kinds of goods procured from the ſavages are doubtleſs valued in a ſimilar manner, although he has not detailed the reſpective proportions. In the catalogue of Britiſh manufactures given in lieu of them, he enumerates the following; "glaſs-beads, black-lead, ſugar, thread, vermilion, brandy, broad cloth, blankets, duffels, flannel, awl-blades, buttons, fiſh-hooks, fire-ſteels, files, guns, flints, yarn, mittens, handkerchiefs, hats, hawk-bells, knives, ice-chiſſels, looking-glaſſes, needles, net-lines, rings, runlets, ſword-blades, ſpoons, ſhirts, ſhoes, ſtockings, ſaſhes, worſted, thimbles, tobacco-boxes, tongs, trunks, wine, &c. &c."

This year, 1730, the company imported 11,040 coat and parchment beaver ſkins; 4404 do. cubs; 3330 damaged and ſtage-parchment; 990 do. cubs; 1648 martens, 3130 damaged do.; 380 otter ſkins; 890 cat ſkins; 260 fox ſkins; 540 woolverins; 400 black bear ſkins; 190 wolves ſkins; and 30 wood-ſhocks. In 1737, the company exported to the value of 4124*l.* 18*s.* 2*d.* The year following, 3879*l.* The ſame author gives the following ſtatement of one of the company's ſales in the year 1740, *viz.* "17,780 beaver ſkins, and 49,600 ſkins of all kinds, 2360 pound weight of bed feathers, 160 of caſtoreum, 610 whale fins, and 120 gallons of whale oil." He further obſerves, "that as there are two ſales every year, and the company reſerves three-fifths of their beaver ſkins for their ſecond ſale, but no other ſkins; then the ſecond ſale muſt have had 26,670 beaver ſkins, and both the ſales muſt have furniſhed 44,450 beaver ſkins." He has alſo given the company's entire ſale for the year 1743, with the prices affixed, *viz.*

		£.	s.	d.
26,750	Beaver-ſkins, ſold for	9780	4	0
12,370	Martens ſkins, do.	4242	7	0

A literary controverſy, between Mr. Dobbes and Capt. Middleton, concerning the paſſage through Hudſon's bay weſtward to China, and the nature of the company's trade with the ſavages, has brought to light more particulars for the illuſtration of this ſubject, than either the company would have been inclined, or the public could have expected them to communicate. Upon the allegations, in theſe and other pamphlets, reſpecting a north-weſt paſſage to the ſea of Japan, that the Hudſon's bay company had not hitherto encouraged any attempts for the diſcovery of ſuch a paſſage, and that a more extenſive and beneficial commerce might be carried on with the countries bordering on the bay, if the trade were laid open; the houſe of commons appointed a committee to inquire into the truth of ſuch ſtatements. By the papers and books produced on that occaſion, it appears the original fund of the company was 10,500*l.* This, in the year 1690, was trebled, making 31,500*l.*; which was again trebled in 1720, amounting to 94,500*l.*; and by a partial payment of 10*l.* per cent. on a new ſcheme of enlargement, the capital was augmented to 103,500*l.* Mr. Robſon, who had ſome years been ſurveyor for the company, and on this occaſion ſeemed rather a diſguſted evidence againſt them, informs us the company's four ſmall factories contained only 130 ſervants, and two ſmall houſes, with eight men in each; the value of their annual exports was about 4000*l.*; and that in time of peace they employed three ſhips of 150 to 200 tons burthen, with two or three ſmall ſloops, conſtantly ſtationed in the bay. The company, he obſerved, have always been extremely averſe either to make diſcoveries, or permit others to attempt ſuch undertakings, apprehenſive, whenever the improvable value of the colony and trade ſhould be known, government might be inclined to take the one under its own protection, and to lay open the other to the nation at large. They, therefore, have contented themſelves with dividing among only a hundred perſons a large profit upon a ſmall capital. This profit, according to his ſtatement from the documents laid before the parliament, is enormous. Taking the beaver ſkin as the ſtandard, he thus proceeds, "for a quart of Engliſh ſpirits, which the company export at ſix-pence, and before they ſell it to the natives, mix it with one-third water, which reduces it to four-pence; they take a beaver ſkin, which has been ſold at the company's ſale, at a medium of ten years, for ſix ſhillings three farthings the pound, and a beaver-ſkin generally weighs a pound and a half; ſo that they get nine ſhillings and one penny for four-pence, which is 2700*l.* per cent. profit. Upon other articles not ſo material, they do not gain above 500*l.* or 600*l.* per cent.; but in exchange for martens the profit is double of that upon beaver; for they value three martens only as one beaver, and thoſe, at a medium of ten years, have ſold for ſix ſhillings a ſkin. It appears alſo from the ſtandard that one-third more is charged upon many articles at Nelſon and Churchill factories, than at Mooſe and Albany; thoſe factories being farther from the French, who till within theſe few years had not intercepted the trade there; and not content even with this extravagant profit, the factors are allowed to ſell their goods conſiderably above the ſtandard, which is called the profit upon the *overplus* trade; yet with all this advance upon their goods the company is reduced by the expence of management, ſhipping, factories, officers, and ſervants, to a little more than 200*l.* per cent. For by a medium of ten years trade, their ſales amount annually to 27,354*l.* 5*s.* 5¼*d.* and their expences to 19,417*l.* 8*s.* 6*d.*; their net profit, therefore, at the ſame medium, amounts to 7,936*l.* 16*s.* 11¾*d.* which upon 3,674*l.* 3*s.* 1¾*d.*, their annual export at the ſame medium, is about 216*l.* per cent. profit upon the annual ſtock in trade, and near 7⅔*l.* upon the

the nominal capital of 103,95*l.*"—But from this ſtatement, compared with Mr. Dobbes's, the profits of the concern are by no means ſo enviable as might at the firſt glance be imagined. For upon viewing the proceeds of the company's ſales, it may be obſerved, that if their capital ſtock be about 100,000*l.* that thereon they had not for many years divided more than 10*l.* per cent, and if the ſale in 1743 be any rule to determine for other years; the reſt being abſorbed in the company's annual expences for ſhipping, forts, garriſons, ſalaries, and home charges, which may amount to about 20,000*l.* So that although Mr. Dobbes has evidently ſpared no exertions to become maſter of his ſubject, yet, after all, conſidering the riſks to which the company are conſtantly liable, their gains, as captain Middleton obſerves, "are little to be envied. Indeed their recent dividends of eight per cent. form no very alluring object for mercantile ſpeculation. The laſt mentioned author, in his pamphlet, printed in 1743, ſtates, "that until a little above twenty years before, the voyage to Hudſon's bay was ſeldom made without wintering there." This ſhews the company have by that alteration made a conſiderable improvement, and great ſaving muſt accrue from ſuch an economical meaſure. But the exiſting neceſſary expences might be materially diminiſhed, except in the article of freight, if the trade were laid open, the country ſettled, and the poſſeſſions thus ſecured without charge; whilſt the exports and imports would be greatly increaſed, perhaps as ſome have calculated, to one hundred times their preſent value, for there is a ſufficient ſcope; and an extent of country, which by proper cultivation, and due encouragement to the natives, to ſupport the computation. Indeed this latter meaſure, the civilization of the Indians, is highly deſirable; for by inſtructing them in the knowledge of uſeful arts, and inducing them to attain habits of induſtry, by allowing a fair and equitable trade, a ſolid foundation might thus be laid for their converſion to Chriſtianity.

Reſpecting the future progreſs of the trade, and the nature of its concerns, little more can be collected than what is furniſhed by the invoices of the cargoes, imported in the company's ſhips; and the reports of their public ſales. For ſubſequent to the parliamentary inveſtigation they have been unuſually jealous of inquiry, and peculiarly tenacious of information. A few notices, extracted from theſe, will ſerve to elucidate ſimilar kinds of ſtatements; which will be found in the ſubſequent account of the Canadian branch of this commerce. From the time of Mr. Dobbes's ſtatement, the concern for ſome years was evidently on the decline; but after the American war had terminated in eſtabliſhing the independence of the United States, this, among other kinds of traffic, was more vigorouſly purſued with thoſe parts of America ſtill ſubject to the crown of Great Britain. The importation of the year 1789 affords the following reſult, *viz.*

"Coat beaver ſkins 4,900; parchment ditto 26,750; cub ditto 14,900; marten 25,900; otter 2,650; cat 1,530; fox 3,790; woolverin 240; bear 400; wolf 2,420; fiſher 160; mink 460; raccoon 480; muſquaſh 5,200; elk 26; deer in the hair 2,980; rabbit 5,000." In the year 1791 the company made an alteration in the mode of ſale. Inſtead of allotting the different ſkins and furs according to their kind, they arranged each kind in ſix different claſſes, according to their reſpective goodneſs and value; but more eſpecially with the view to the various uſes to which they might be applied. By the adoption of this plan, the company became wholeſale furriers, as well as importing merchants; and by dividing of qualities, and deſignating uſes, united the double profits of two very beneficial concerns.

The following is the ſtatement, in the report of the ſale for 1791.

	AR	MR	EM	YF	SR	CR

Squirrel	—	—	152	144	—	20

The greateſt importation the company appears to have made, was in the year 1794, which amounted, as per invoice of cargoes, to 37,777 parchment beaver ſkins; coat do. 4024; cub do. 14,740; and the various kind of ſkins nearly in an equal proportion. From this period the decline of imports is evident from almoſt every annual ſale report. That for 1807 and 1808 will exhibit very nearly the preſent ſtate of the company's trade.

Swan	—	—	—	396	—	—

The following is the amount of the quantity imported by the Hudſon's bay company in the year 1808, as appears from the ſale report for 1809, *viz.* beaver coat 1684 lbs.; ditto whole parchment ſkins 20,821; ditto cub ditto 12,063; muſquaſh 33,706; otter 5077; cat 2788; fox 1370; ditto kitt 2371; woolverin 163; bear, black, 971; ditto, white, 89; wolf 3704; fiſher 71 mink 3185; raccoon

coon 5339; deer 5339; ſwan 1067; ſquirrel 905; rabbit, 25,914. The higheſt price of coat beaver was nineteen ſhillings and ſixpence per pound, the average fifteen and ſixpence; parchment ditto twenty-three ſhillings and ninepence, average ditto, twenty-one ſhillings and fourpence; cub ditto, twenty-three ſhillings, average ditto, twenty-one ſhillings and eight-pence. In this ſtatement, it is proper to obſerve, that theſe prices were obtained for the prime and fair articles; what are called damaged and *ſtaged* ſkins, of which there is a very conſiderable portion in every annual importation, are ſold at very inferior ſums.

Canada, the grand entrepot, or market of communication for the trade in furs and peltry, was firſt colonized by the French, who viſited America for the purpoſe in 1540; when M. Cartier and baron Roberval, with about 200 men and women, as ſettlers, ſailed from St. Maloes with five ſhips, and proceeded up the river St. Lawrence, four leagues above the haven of St. Croix; where, having landed, they conſtructed a fort for the protection of the infant colony. Emigration and population proceeded ſo rapidly, that the country, near the north bank of the river St. Lawrence, ſoon became well peopled, ſo that from the account given of it by governor Lahontan, about the end of the ſixteenth century, the number of inhabitants amounted to 180,000. In the year 1603, the French went higher up the river, and began to ſettle in the country now called Canada, or New France, on the north ſide of the river, and erected houſes at the point of Trois Rivieres; but they did not extend ſo high as Quebec till the year 1608. They continued to erect habitations and forts in the ſame direction, between Quebec and Montreal till 1629, when the country was taken by an Engliſh force under the command of ſir David Kirk, but was ſhortly reſtored again to France. For a ſeries of years this valuable territory was much neglected by the mother country. During a long time the further colonization was left to private individuals, who fitted out expeditions of adventure at their own expence. Theſe were uſually men of rank and fortune, who obtained from the government an excluſive right to trade with the native Indians for divers kinds of furs and peltries, then the principal articles of Canadian commerce. But experience quickly demonſtrated that theſe expeditions were upon too ſmall a ſcale to inſure either the ſucceſs or the ſafety of the ſettlers, who were conſequently ſubject to be haraſſed by continual incurſions of the Indians for the ſake of plunder. From the year 1535, when it is ſaid Quebec was firſt diſcovered, to the year 1664, the government and trade of Canada were entruſted to private merchants, holding under patents, granted by the king of France. In the year 1664, the two departments were ſeparated, and changed poſſeſſors; the crown aſſuming the government, while the trade was put excluſively in poſſeſſion of the company des Indes Occidentales. But even after the French government had taken the colony under its own more immediate care, greater attention appears to have been paid to the ſpreading of the Roman catholic religion, by numerous miſſionaries exploring the interior, and cultivating friendſhip with the various Indian tribes, for the furtherance of the fur trade; than to the internal improvement of the country, by agriculture and arts. Indeed, from the firſt ſettlement of Canada, the fur trade was conſidered of the greateſt importance to the colony. Soon in the vicinity of the trading ſettlements, the ſkins of ſuch animals as were deemed precious in a commercial view, became ſcarce and daily more valuable. To procure the neceſſary ſupplies, the Indians were conſtrained to penetrate farther, and explore the diſtant woods for hunting purſuits, in which they were often accompanied by native Canadians. Theſe in time, by means of the intercourſe they thus obtained with perſons belonging to the remoter tribes, induced the latter to bring to the ſettlements belonging to the trade the kind of ſkins which were moſt in demaud. Such Canadians, who thus conſorted with the Indians in theſe hunting excurſions, were denominated "Coureurs des bois," and becoming a kind of pedlars or middle men, proved extremely uſeful to merchants engaged in the trade; who found it their intereſt to grant the neceſſary credit, to enable them to undertake their commercial ſpeculations. Three or four of theſe pedlars would put their property, as a joint ſtock, into a canoe conſtructed of birch-bark, which they would navigate up the rivers and lakes, and either aſcend to the places where the natives were accuſtomed to hunt, or to ſuch as they were uſed to frequent, for the purpoſes of trade. At length, to ſuch an extent did they proceed, that theſe voyages would take up from twelve to fifteen months, when the adventurers would return freighted with rich cargoes of furs, attended by numerous canoes, containing ſtill more, belonging to the Indians. The diſſolute lives of theſe men, however, tending to obſtruct the work of the miſſionaries, and leſſen the Canadians in the eyes of the natives, the ſuppreſſion of ſuch a claſs of men was attempted by an edict prohibiting any perſon from going up the country without a licence from government. But theſe licences being transferable, many of them came into the hands of the merchants, who, as they formerly did, had recourſe to the agency of the coureurs des bois, which cauſed a renewal of the former complaints; in conſequence of which, military poſts were eſtabliſhed at the confluence of the different large lakes of Canada; a meaſure which tended in a great degree to check the evil conſequences ariſing from the improper conduct of the foreſters. The trade alſo flowed in more numerous and profitable channels. Many reſpectable men, retired from the army, proſecuted the concern in perſon with great regularity, under their reſpective licences; and by perſevering induſtry extended it to ſuch a diſtance, as in that period was conſidered an aſtoniſhing effort of commercial enterprize. Theſe traders, and their miſſionaries, having combined their views, and agreed to act with concert, in the courſe of time ſecured the reſpect of the natives, and the obedience of the people neceſſarily employed in the laborious departments of the concern. Theſe religious men were of extenſive ſervice to the *commanders*, as the licenced traders were denominated, engaged in thoſe diſtant expeditions to the remote ſettlements, and enabled them to carry the fur trade as far as the banks of the river Saſkatchiwine, in latitude 53° north, and longitude 102° weſt. Thus expanded was it, notwithſtanding the reſtrictions by which commerce was oppreſſed under the French government; and thus did it ſurmount many of the moſt diſcouraging obſtacles; while at the ſame time no exertions were made from the people of Hudſon's bay to obtain the ſmalleſt ſhare in the trade of a country, which, according to the charter of that company, formed part of their own poſſeſſions; and, from its proximity, is acceſſible with ſo little comparative difficulty to the mercantile adventurer.

What the quantity of furs and ſkins was, on an annual average, that France imported from Canada, previouſly to the ceſſion of the province to the Engliſh, it is not eaſy accurately to aſcertain. Mr. Dobbes has given an enumeration of the peltry imported in the year 1743 by the port of Rochelle, the principal import place, *viz.* beaver ſkins 172,080; bear do. 16,512; raccoon do. 110,000; marten do. 30,325, otter and fiſher do. 12,428; mink do. 1700; fine cat do. 1220; wolve do. 1267; woolverins 92; grey fox,

fox, and cat do. 10,280; red fox do. 451: total 311,355 ſkins, worth about 120,000 *l.* ſterling.

On the 8th of September, 1760, the town of Montreal, together with the reſt of Canada, was ſurrendered to the Britiſh forces, under the command of general Amherſt, by the French general M. Vaudreulle; and in the treaty of peace, concluded in 1763, the whole province, and its dependencies, were ceded to Great Britain. From this invaluable acquiſition, not only did the country obtain a vaſt addition of territory; but, what is of very great importance, became poſſeſſed of the entire fur and peltry trade of the American continent. And though a portion of it was again alienated by the act, which declared the independence of the United States, yet while we retain the country on the banks of the great river St. Lawrence, the key to the lakes, and the land of furs, it muſt ever be carried on by this kingdom to the moſt conſiderable extent. Canada now become a Britiſh province, the lords of plantation addreſſed the king, that the trade might be put under the ſame regulations with that of the other colonies, except ſuch caſes as might be otherwiſe provided for by the articles of capitulation and ceſſion. Large orders for furs were now forwarded to this country from Flanders and other places on the continent, and even from Ruſſia, which, though conſidered a fur country, does not produce a ſufficient quantity for the ſupply of its own wants. But though the demands in the market were great, yet for ſome time after the conqueſt this trade appeared almoſt ſuſpended; owing to an ignorance of the country in the conquerors, their want of commercial confidence in the conquered, and the numerous diſcouragements ariſing from the hoſtile diſpoſitions of the Indian tribes, who had been in alliance with the French. Hence it was, that ſo late as the year 1766, the trade from Michilemakinac only commenced. In the undermentioned years, Mr. Macpherſon gives the number of ſkins, or furs, exported from the province of Canada, according to the returns from the offices at Quebec; where the ſpecies of furs are not diſtinguiſhed, but ſimply entered under one head of, "peltries, ſkins,"

1764, 106,035 ſkins, beſides 58 caſks, 207 bales, and 1 trunk, whereof the contents are not aſcertained.
1765, 275,206.
1766, 346,749.

Some of the adventurers now proceeded beyond Grande Portage, ſituated on a bay in latitude 48° north, and 90° weſt longitude, which has ſince that period become the principal north-weſtern entrepot of the trade. Subſequent to this an adventurer, by the name of Mr. Thomas Curry, having penetrated to the furtheſt limits of the French diſcoveries in the fur country, and returned with a ſucceſsful cargo; numerous perſons were encouraged to embark their capital, and engage in the concern, and they, or their agents, began to ſpread over every part of the country, particularly where the French ſettlements had previouſly been eſtabliſhed. The trade was now purſued with ſuch avidity and irregularity, that in a few years it became the reverſe of what it ought to have been, for the benefit of the perſons concerned. An animated competition prevailed, and the contending parties carried the trade beyond the line of domarcation laid down by the French, though with little advantage to themſelves, and to the ſerious injury of their neighbours, the Hudſon's bay company, who, in the year 1774, and not till then, thought proper to move their depot and factory to the eaſt bank of Sturgeon lake, in latitude 53° 56 north, and longitude 102° 15' weſt. Rouſed from torpidity, they now evinced more jealouſy towards their fellow ſubjects, and perhaps with greater reaſon than they had ever done towards thoſe of France. This competition, and many other incidental circumſtances, for ſome conſiderable time, injured the Canadian trade; and which, by the irregular mode it was conducted, yearly grew worſe and worſe. About this time that direful malady, the ſmall-pox, raged with uncommon virulence among the Indian tribes, and as Mr. Mackenzie deſcribes it, "the fatal infection ſpread around with a baneful rapidity which no flight could eſcape, and with a fatal effect that nothing could reſiſt, ſpreading its deſtructive and deſolating power as the fire conſumes the parched graſs." Theſe combined circumſtances reduced the fur trade of Canada to a forlorn condition. During the winter of 1783—4, the Canadian merchants engaged in this concern formed a junction of intereſts, under the name of the North-weſt Company; who divided their firm, for capital they had none, into ſixteen ſhares; each partner furniſhing a proportionate quota of ſuch articles as were neceſſary for carrying on the Indian intercourſe. The traders in the country, forgetting their former animoſities, and with the expectation of having their labours adequately rewarded, entered into a co-partnerſhip with the merchants of Montreal, engaging with the utmoſt ſpirit and activity to further the general intereſt. The trade, thus conſolidated, was directed by able men, who, from the powers with which they were entruſted, were enabled to carry it on to the utmoſt capable extent. In the year 1787, this company was joined by a rival company, which had ſtarted ſoon after the firſt was formed, and in which Mr. Alexander Mackenzie, the author of "Voyages from Montreal, &c." bore a diſtinguiſhed part. This commercial eſtabliſhment was, by union of ability, and local knowledge, founded on a more ſolid baſis than hitherto had been known in the country; and it not only continued in full force, vigour, and proſperity, in defiance of all interference from Canada, but maintained at leaſt an equal ſhare of advantage with the Hudſon's bay company, notwithſtanding the decided ſuperiority of their local ſituation. This new, or combined North-weſt company, conſiſted of twenty ſharers; of theſe, ſome were called the company's agents, and managed the concerns in Canada. Two went annually to the Grande Portage to tranſact the buſineſs there; while others were obliged to winter among the Indians, and to conduct the intercourſe with the reſpective tribes. By ſuch wiſe commercial arrangements, and prudent minor regulations, did the ſelf-created company inſure its ſubſequent ſucceſs. In the year 1788, the groſs amount of the annual adventure did not exceed forty thouſand pounds, which might be conſidered at that time the *ſtock* of the company; but by the exertion and enterprize of the proprietors, it was brought in the ſpace of eleven years to upwards triple that amount; yielding proportionate profits, and ſurpaſſing every thing in this department of commerce ever before witneſſed in America. Such a proſperous ſtate of affairs induced others to embark in ſimilar undertakings. In 1798 the concern underwent a change, the ſhares were increaſed to forty-ſix. This produced the termination of the company, which was not renewed by all the parties previouſly concerned, the majority continuing to act under the old firm, and the reſt ſetting up another, under the name of the South-weſt company; a title the eſtabliſhment aſſumed from the circumſtance of the furs in which they trade being brought from the Indian ſettlements in the weſtern parts of America, in the vicinity of the rivers Ohio, Miſſouri, and Miſſiſſippi. This trade had been carried on individually by the perſons forming this company, who, by interfering in each other's concerns, did themſelves a deal of injury which is now avoided by their union. But it yet

remains

remains to be decided, whether two parties under the ſame regulations, and by ſimilar exertions, though unequal in number, will be able to continue carrying on the buſineſs to a ſucceſsful iſſue. The contrary opinion has been entertained by many, which, if verified, will make it the intereſt of the parties again to coaleſce; for neither appears deficient in capital, to ſupport their reſpective claims on a market, and it is not probable that either will relinquiſh them on any other terms, than perpetual participation.

Theſe two companies have nearly monopolized the fur-trade, for having ſcarcely any competitors, they have in a great meaſure the Indian market in their own power; but they are obliged to pay latterly an advanced price for their ſkins and furs; becauſe the Indians, ſo long accuſtomed to the trade, have long ſince learned, that a beaver ſkin is worth more than a two-penny knife, or a ſix-penny trinket.

By the printed documents of the annual importations from Canada, the quantity of furs and ſkins, which arrived in England in the year 1783, was as follows: "96,000 parchment beaver; 3000 coat ditto; 105,000 deer in the hair and ſhaved; 10,000 ditto Indian; half-dreſſed, 85,000; 10,500 bear; 17,700 otter; 3400 fiſher; 40,000 marten; 5600 wolf; 300 woolverin; 7300 cat; 6400 mink; 3900 fox; 3600 elk; 65,000 muſquaſh."

After the north-weſt company had been formed, how very conſiderably the trade was increaſed by their united exertions, will appear from the imports of 1784, *viz.* "116,000 parchment beaver; 4000 coat ditto; 130,000 raccoon; 40,000 marten; 19,000 otter; 11,000 bear; 7000 wolf; 8000 cat; 8000 mink; 6000 fox; 4000 fiſher; 300 woolverin; 6000 elk; 160,000 deer in the hair and ſhaved; 5000 Indian ditto half-dreſſed; 84,000 muſquaſh."

Subſequent to the junction of the two rival companies in 1788, the trade was ſtill further extended, and a much larger quantity of furs were brought into the Engliſh market. The invoices of the cargoes belonging to ſundry ſhips, which arrived from Canada in the year 1791, give the following reſult, and it forms the greateſt annual importation ever made from that country, *viz.* "168,000 parchment beaver ſkins; 5500 coat ditto; 178,000 raccoon; 37,000 marten; 22,500 otter; 15,600 bear; 9600 wolf; 9400 cat; 21,000 mink; 11,000 fox; 600 fiſher; 650 woolverin; 147 muſquaſh; 86,000 deer in the hair and ſhaved; 1000 ditto half-dreſſed; 2000 elk." The two enſuing years were nearly as productive; but after the diſſolution of the company, and the partial reformation of a ſimilar firm, the annual imports began to decline. Thus the import of 1799 gives the following ſtatement, *viz.* "113,000 parchment beaver ſkins; 1200 coat ditto; 126,000 raccoon; 34,500 marten; 16,000 otter; 21,000 bear; 5900 wolf; 12,500 cat; 8000 mink; 7800 fox; 5400 fiſher; 780 woolverin; 6000 muſquaſh; 160,000 deer in the hair and ſhaved; 1000 elk." From this period, though the quantity imported in one or two years exceeded that of 1799; yet the average arrivals have fallen ſhort of it. Thus the report of 1803 gives, "93,000 parchment beaver ſkins; 200 coat ditto; 150,000 raccoon; 32,000 marten; 17,000 otter; 25,000 bear; 5600 wolf; 14,000 cat; 12,000 mink; 10,000 fox and kitt; 57,000 fiſher; 1400 woolverin; 76,000 muſquaſh; 204,000 deer in the hair and ſhaved; 600 elk." The year following produced rather more, and the ſucceeding one much leſs. The reſult of 1803 will ſerve to give a general view of the preſent ſtate of the trade: "106,000 parchment beaver ſkins; 125,000 raccoon; 54,000 marten; 12,000 otter; 16,000 bear; 1000 wolf; 5,300 cat; 15,000 mink; 10,000 fox. N.B. 2300 white; 7000 fiſher; 200 woolverin; 15,500 muſquaſh; 216,000 deer in the hair and ſhaved; 800 elk."

What have been the cauſes of this gradual diminution in the quantity brought to market has been a ſubject of ſerious inquiry. By ſome it has been attributed to the interference of the Hudſon's bay company; and their agents, engroſſing a conſiderable portion of the intercourſe with the Knifteneaux, Chepewyan, and other tribes of Indians, who uſed excluſively to trade with the Canadian adventurers. But by reverting to the ſtate of the ſales belonging to that company, it will be evident this could not have been the cauſe, for the arrivals in the market through that channel alſo have been progreſſively growing leſs. Two reaſons may be aſſigned for the defalcation. Firſt, the diſtance the adventurers are obliged to go to meet with new Indian tribes for the purpoſe of profitable barter, and the expenſive range the hunters are neceſſitated to take, for ſucceſsful purſuit in procuring ſaleable ſkins. A ſecond reaſon may be found in the recent formation of a new company at New York for carrying on the fur-trade in the United States; who, though at preſent they do not much annoy the Canadian traders by their rivalſhip in the commerce of the extenſive lakes; yet by the quantity of furs they import from Canada, for the purpoſe of ſupplying the Chineſe, they occaſion a conſiderable drawback on the quantity of goods which otherwiſe would be expoſed in the Engliſh market. Theſe two co-operating cauſes have had a conſiderable influence, both upon the trade in Canada, and alſo at Hudſon's bay; and they furniſh two powerfully perſuaſive arguments, why the intercourſe ſhould be extended and improved with the countries bordering on the north-weſt coaſt of America.

The prices of this article have been progreſſively riſing, not merely, as ſtated by ſome, on account of the leſs quantity brought into the market; but from more powerful though leſs obvious cauſes. The competition, which has tended to enhance the value, has ariſen from a different quarter. Luxury ramifying and increaſing through all ranks and gradations of ſociety, has been the primary and continuative cauſe of the average advance in the price of furs. Other incidental cauſes may have occaſioned temporary fluctuations; but theſe ſoon ceaſing to operate, the trade reverted to its uſual level. The leading and grand cauſe is, that change that has taken place in the national manners of this country; which is technically couched under "the nature of the trade." To inſtance, reſpecting beaver, where ſome years ſince one perſon wore a hat fabricated from that ſpecies of fur, a thouſand probably do at preſent. Formerly muffs, tippets, and furred garments were only worn by people of quality, or diſtinguiſhed the upper claſſes of gentry. Now coſtly furs adorn the dreſs of females in that ſphere of life, in which perſons at no remote period were uſually clad in the plaineſt and moſt homely attire. To this may be added the expence of freight, inſurance, &c., owing to a protracted war. And the indirect influence of general taxation, as well as the effects of a direct impoſt, and an additional fifteen per cent. lately put upon the article, ſubjects the conſumer to an accumulated charge. It is not requiſite to enter into details minutely to inveſtigate the ſcale of gradation, or mark the different periods of advance; ſuffice it to obſerve, that by the ſale prices of the Hudſon's bay company, on an average of eleven years from 1722 to 1733 incluſive, the price of beaver, which to a certain extent regulates the reſt, ſold from three ſhillings and three-pence to ſeven ſhillings and ſix-pence per pound, forming a medium of five ſhillings and four-pence halfpenny. By the accounts laid before parliament in 1749, the average price, reckoning for ten years prior to that period, of a pound weight of beaver, was

ſix

ſix ſhillings and three halfpence. Since that time it has variouſly fluctuated, but ſtill kept progreſſively riſing; till at one time it had advanced to the enormous height of thirty ſhillings per pound. It then fell conſiderably, and at preſent maintains the average rate of *twenty-four*. Mr. Gray, who in his account of Canada frequently alludes to the fur trade, furniſhes a few remarks, calculated to illuſtrate this ſubject; for by contraſting the prices at the London ſales with thoſe of Canada, which he gives in his ſtatement, it will be ſeen, that not monopoly, but the increaſing demand in the market, and the difficulty of ſupplying it, have been the actual cauſes of the advance in price.

The following were the quantity, kinds, and prices of furs and peltry exported from Canada to Britain, on an average of three years ending 1805, *viz.*

				£.	s.	d.
Beaver ſkins	99,076	average weight each 1⅓lb. at 14*s.* per lb.		92,470	18	8
Marten	21,370	at 4*s.* each		4,634	0	0
Otter	17,649	— 17*s.* 6*d.*		33,091	17	6
Mink	11,687	— 2*s.* 6*d.*		1,460	17	6
Fiſher	5,657	— 8*s.* 6*d.*		2,404	4	6
Fox	8,636	— 12*s.*		5,181	12	0
Bear and cub	20,074	— 40*s.*		40,148	0	0
Deer	223,290	— 5*s.*		55,822	10	0
Raccoon	151,710	— 2*s.*		15,171	0	0
Muſkwaſh	79,650	— 1*s.* 2*d.*		4,646	5	0
Cat, caſed and open	12,221	— 7*s.* 6*d.*		4,582	7	6
Wolf	6,425	— 8*s.*		2,570	0	0
Elk	1,032	— 10*s.*		516	0	0
Woolverin	1,250	— 5*s.*		812	10	0
Hare, Rabbit, Ermine, Squirrel	3,062	— 8*d.*		76	11	0
			Total in value	£ 263,088	13	8

Excluſive of this part of the trade, a large quantity of furs of all deſcriptions are annually ſent by way of St. John's into the United States; not merely for ſupplying the demands of that country, but for exporting to China, for which market the fineſt furs and prime peltries are in requeſt. The amount of theſe articles ſold to the Americans in the year 1806, Mr. Gray ſtates at 62,009*l.* 15*s.* 2*d.* The reaſon of the furs being ſent by this channel, rather than through the London market, is the difficulty of getting home the produce obtained for the furs in China by the Eaſt India company's ſhips, together with the various reſtrictions laid by the directors, and the heavy duty payable on the exportation.

Mr. Gray's account of the exports of furs and peltries from Quebec in 1808, is as follows, *viz.*

				£	s.	d.
Beaver	126,927	at	18*s.* 9*d.*	118,994	1	3
Marten	9,530	—	3*s.* 4*d.*	1,588	6	8
Otters	7,230	—	20*s.*	7,230	0	0
Mink	9,108	—	2*s.*	910	16	0
Fiſhers	3,866	—	4*s.*	773	4	0
Foxes	1,038	—	5*s.*	259	10	0
Bears and cubs	1,298	—	25*s.*	1,622	10	0
Deers	103,875	—	3*s.* 4*d.*	17,312	10	0
Caſed and open cat	5,718	—	3*s.* 4*d.*	953	0	0
Raccoons	123,307	—	2*s.*	12,330	14	0
Muſk cats	6,513	—	1*s.* 6*d.*	488	9	6
Wolf	18	—	7*s.* 6*d.*	6	15	0
Elk	662	—	15*s.*	496	10	0
Woolverins	39	—	5*s.*	9	15	0
Seals	10	—	4*s.*	2	0	0
Buffalo	1	—	20*s.*	1	0	0
			Total value	162,979	1	5

By this ſtatement it will appear that the fur trade to Britain has recently declined; and that many of the articles have ſold at a reduced price, compared with the average amount and prices in 1805.

The Canadian imports, for the year 1808, conſiſted of 92,000 parchment beaver; 3000 coat ditto; 123,000 raccoon; 10,000 marten; 7000 otter; 1300 bear;——wolf; 5700 cat; 9000 mink; 1000 fox; 3900 fiſher;——woolverin; 5400 muſkwaſh; 103 deer, in the hair and ſhaved; 600 elk. The higheſt price obtained for parchment beaver was twenty-one ſhillings, the average twenty; cub ditto, twenty-five, average ditto twenty-three and ſix-pence; coat ditto, fourteen and five-pence, average ditto eleven and tenpence. By comparing this ſtatement with the one previouſly given from the ſale-report of the Hudſon's bay company, for the ſame year, it will appear, that notwithſtanding the gradual defalcation in the quantity of furs brought from Canada, yet the importation from that country is nearly treble the amount of that from Hudſon's bay; and that the price of coat-beaver from the former country is conſiderably lower than what is brought from the latter, while the cub and prime parchment beaver reaches a higher ſtandard. This difference can only ariſe from the quality of the reſpective articles, ſince the ſales are conducted on a ſimilar plan, *viz.* "by the candle at a public auction." To explain the general mode of carrying on the fur trade, and conducting the neceſſary interchange of commodities with the Indians, it will be neceſſary to have recourſe to the details given on this ſubject by that intelligent merchant and obſervant traveller, Alexander Mackenzie, whoſe voyages of diſcovery in the interior, indefatigable labours for the furtherance of this branch of commerce, and the proſperity of our northern ſtates in America, deſerve the higheſt encomium; and doubtleſs his fame, with his valuable works, will deſcend to the lateſt poſterity. The facts which thoſe afford will be interſperſed with others furniſhed by Hearne, Vancouver, Gray, &c. &c. with

with ſuch additional remarks as may tend to the elucidation of the ſubject.

The commercial relations with the Indians form purely a barter trade, as money is of little value in a country where every thing bought and ſold is, and muſt be, in kind. The articles neceſſary for the trade are, coarſe woollen cloths of various kinds, milled blankets of different ſizes; arms and ammunition; twiſt and carrot tobacco; divers ſorts of Mancheſter goods; linens and coarſe ſheetings; threads, line, and twine; common hardware; cutlery and ironmongery of ſeveral deſcriptions; braſs and copper kettles; ſheet iron; ſilk, and cotton handkerchiefs; hats, ſhoes, and hoſe; calicoes, printed cottons, &c. &c. Theſe are imported from England. Spirituous liquors, and divers articles of proviſion, are purchaſed for the concern in Canada. Theſe goods are previouſly made up, and properly prepared for the Indian market at Montreal. The expence of this, the tranſporting them to the Indian territory, and freighting back the goods obtained in exchange, including wages to clerks, interpreters, guides, and canoe men, conſtitute about half the annual amount againſt what is termed *the adventure*. Theſe are conveyed by bateaux, flat-bottomed boats, and canoes, which commence their voyage at La Chine, about nine miles above Montreal, the rapids in the river St. Lawrence preventing the working up loaded canoes between thoſe two places. Some proceed by way of lakes Ontario and Niagara, &c.: but the greater number by the river Altawa, or Outawais, and by other rivers and portages, to lake Nipiſſing, lake Huron, lake Superior, and thence by ſeveral chains of large and ſmall lakes and rivers to lake Winipey, Athabaſca, or Arathapeſcow lake, and the great Slave lake, which is within a few hundred miles of the weſtern coaſt of North America. In this range of their trade the company have at times from one to two thouſand people in their employment, as their agents and ſervants, at their numerous poſts, diſperſed over the country, who conduct the buſineſs and cultivate the friendſhip of the Indians, among whom ſome of them conſtantly reſide. At one particular period Mr. Mackenzie thus particularly ſtates the number of men employed in the concern by the North-weſt company. "Fifty clerks, ſeventy-one interpreters and clerks, one thouſand one hundred and twenty canoe men, and thirty-five guides. Of theſe, five clerks, eighteen guides, and three hundred and fifty canoe men were engaged for the ſummer ſeaſon in going from Montreal to the Grande Portage in canoes; part of whom proceeded from thence to Rainy lake. Theſe, which are called porkeaters, or goers and comers, and hired in Canada or Montreal, were abſent from the firſt of May till the latter end of September. For this trip the guides had from eight hundred to a thouſand livres, and a ſuitable equipment; the foreman and ſteerſman from four to ſix hundred livres; the middle men from two hundred and fifty to three hundred and fifty livres, with an equipment of one blanket, one ſhirt, and one pair of trowſers, and were maintained during the voyage at the expence of their employers. Independent of wages, they were allowed to traffic, and many of them earned to an equal amount. About one-third of theſe proceeded to winter, and had more than double the above allowance and equipment. All the reſt were hired by the year, and in ſome inſtances for three years. Of the clerks, many of them were apprentices, who were generally engaged for five or ſeven years, for which they had only one hundred pounds, with proviſion and clothing."

The neceſſary number of canoes having been purchaſed, at three hundred livres each, the goods formed into packages, of about eighty or ninety pounds weight, and the lakes, with their connecting rivers, free of ice, which generally happens by the beginning of May, the voyagers, with their veſſels and cargoes, are diſpatched from La Chine. Eight or ten men are appointed to each canoe, and their baggage, proviſions, ſtores, with other neceſſary articles, and ſixty-five packages of goods, are ſtowed into this ſmall veſſel. "An European, on ſeeing one of theſe ſlender veſſels, (ſays Mr. Mackenzie,) thus laden, heaped up, and ſunk with her gun-wale within ſix inches of the water, would think his fate inevitable in ſuch a boat, when he reflected on the nature of her voyage; but the Canadians are ſo expert, that few accidents happen." The canoe is conſtructed with much ingenuity, it is perfectly light, and by that means anſwers remarkably well the purpoſes for which it is intended. The length of thoſe canoes, which are uſed in the fur trade, is about thirty feet, the greateſt breadth ſix, gradually narrowing towards each end, till they terminate in a point; the bottom is rounded, and they have no keel. A frame is formed of ſlight pieces of light wood, over which is faſtened a ſheathing, compoſed of ſections of bark, taken from the birch tree; theſe are ſewed together with ſilaments from roots of the ſpruce fir tree called *watape*; and the calking, or making the ſeams water-tight, is effected by a ſpecies of gum which hardens and adheres more firmly in the water. "I had the pleaſure, (obſerves Mr. Gray,) of ſeeing both an arrival, and departure of canoes from, and to, the north-weſt territories. It certainly is a curious ſpectacle. The canoes, when they take their departure from La Chine, are loaded to within about ſix inches of the gun-wale, or edge of the canoe. Inſtead of oars, they uſe paddles, which they handle with great dexterity. They ſtrike off, ſinging a ſong peculiar to themſelves, called the "voyager's ſong;" one man takes the lead, and all the others join in a chorus. It is extremely pleaſing to ſee people, who are toiling hard, diſplay ſuch marks of good humour and contentment, although they know, that for a ſpace of more than two thouſand miles, their exertions muſt be unremitting, and their living very poor; for, in the little ſpace allowed in the canoe for proviſions, you find none of the luxuries, and a very ſcanty ſupply of the neceſſaries of life. The ſong is of great uſe; they keep time with their paddles to its meaſured cadence, and, by uniting their force, increaſe its effect conſiderably."

Leaving La Chine they proceed to St. Anne's, within two miles of the weſtern extremity, in the iſland of Montreal, on the lake of the two mountains, which is conſidered the commencement of the Utawas or Outawais river, and preſents itſelf to the voyagers; who, to paſs the rapids of St. Anne, are obliged to take out part, if not the whole, of their lading. From this ſpot they conſider their departure, becauſe near it ſtands the laſt church on the iſland, dedicated to their tutelar ſaint. The lake of the two mountains is about twenty miles long, and contracting its waters forms the river Utawas, whoſe navigation is interrupted, at intervals, by a variety of caſcades and rapids, that either render decharges, or portages neceſſary. By the former are meant places where the canoes muſt unload their cargoes, and the packages be carried over to points, where the river again deepens, and becomes fit for navigation; and by the latter, ſuch places where the obſtacles oblige the voyagers to carry over both canoes and cargoes. Thus they proceed to lake Nepiſingui, from which by French river, in latitude north 45° 53, they enter lake Huron. Hence paſſing the iſland of Michilimakinac, at the confluence of lakes Huron and Michigan, and paſſing along the north ſhore of the former, they portage over the falls of the river St. Mary, which

which extends to lake Superior; and having croſſed that immenſe body of water which forms the grand reſervoir of the river St. Lawrence, they arrive at the important entrepot denominated the Grande Portage. At this place they are met by the northmen, who generally come down about the beginning of July. At this period it becomes neceſſary to ſelect from the pork-eaters a number of men, among whom are alſo the recruits, or volunteer winterers, ſufficient to man the canoes neceſſary for carrying the goods and proviſions requiſite for the Athabaſca country, to the river of the Rainy lake. The northmen, who have arrived at Grande Portage, are regaled, have their accounts ſettled, and ſuch as chooſe to ſend any of their earnings to Canada receive draughts to remit the ſame to their relations. Such as have not previouſly entered into engagements during the winter, as is cuſtomary, now contract for returning up the country, to perform the annual voyage for one, two, or three years; and as ſoon as every thing can be got ready, which uſually requires a fortnight, they are again diſpatched to their reſpective departments. This done, the agents, aſſiſted by their clerks, prepare to return eaſtward, by getting the furs and ſkins acroſs the Portage, and re-packing them in bales of one hundred pounds each, to ſend them down to Montreal, where they commonly arrive about the month of September.

The trade from the Grand Portage to the interior is, in ſome particulars, carried on in a different manner from that between it and Montreal. The canoes employed in the tranſporting goods from the latter place are too large for carrying them beyond the former. Others therefore of about half the ſize, navigated by about four to ſix men, are here procured from the natives. Theſe boats carry, on the average, about thirty-five packages, in which twenty-three are for the purpoſes of trade, and the reſt are uſed for proviſions, ſtores, and baggage. A pilot, or conductor, is appointed to every four or ſix of theſe canoes, and thus loaded, the voyagers embark on the river Autort, on the north ſide of the Portage. Thence proceeding to lake Outard, they enter the Mountain lake, paſs by numerous portages to lakes Roſe, Saginaga, De la Pluie, and De Bois, which contracts into the river Winipic. The courſe is now through various ſmall lakes and rivers, with numerous intervening portages and decharges to the laſt, at the great waters of lake Winipic; between which, and Hudſon's bay, two communications are formed by means of the Severn and port Nelſon rivers. Several other rivers diſcharge their waters into this lake, *viz.* the Dauphin, Red-deer, and Saſkatchiwine: and the whole country, to the ſouth of the latter, abounds in beaver, mooſe-deer, fallow-deer, elks, bears, buffaloes, and numerous other animals, calculated to the trade in furs and peltry. On theſe waters are three principal forts, for the protection of thoſe conducting the concerns. Fort Dauphin, erected by the French, prior to the conqueſt; Red-deer, and Swan-river forts, with ſeveral ſmall detached outpoſts belonging to each. Up the Saſkatchiwine the flotilla of canoes proceeds to Cedar lake, from whence the abovementioned river is navigable to near its ſource. On this fine communication are five principal factories; *viz.* Nepawi-houſe, South-branch-houſe, Fort George-houſe, Fort Auguſtus-houſe, and Upper Eſtabliſhment. Leaving the Saſkatchiwine, the voyagers enter the river that communicates with the Sturgeon lake, on the eaſtern bank of which is ſituated another factory, Cumberland-houſe. Thence the rout lies through Pine-iſland lake, lake de Bouleau, Miron lake, lake de Bois, to the Miſſinipi, called alſo Churchill river. The inhabitants of this part of the country are the Kniſteneaux Indians, whoſe furs the traders for ſeveral years ſucceeded in obtaining till 1793; when the ſervants of the Hudſon's bay company thought proper to ſend their people amongſt them, for the purpoſe of ſecuring their credits, which the natives are apt to forget, and advancing towards the interior by a new line of commercial ſpeculation. Why they had not adopted ſuch a meaſure long previous to this period is not very obvious: for it muſt have been, as the fact has ſince proved, highly beneficial to their concerns. From the ſhort diſtance they had to come, the quantity of goods they were able readily to ſupply, the trade, as experience has evinced, muſt have reverted to them: the Canadian merchants being unable, from the remoteneſs of their ſituation, and other circumſtances, to meet the company's agents upon adequate terms.

The courſe of this river is interrupted by rapids and falls, and the flotilla has yet to paſs by ſeveral ſmall lakes and rivers to Otter lake; thence by lakes de l'Iſle d'Ours, lake des Souris, lake du Serpent, lake Croche, lake Shagoina, lake la Croiſe, lake de Bœuf, up the river la Loche, and thence by the Elk, which communicates with the lake of the Hills, in latitude 58° 36′ north. On the ſouthern ſide of this is ſituated what is termed the "Old Eſtabliſhment," which was the only one in this part prior to the year 1785. It was formed by a Mr. Pond in 1778—9, about forty miles diſtant; and transferred to this place in 1788, by the order of the north-weſt united company. This, called Fort Chepewyan, is in latitude 58° 38′ north, and longitude 110° 26′ weſt. This was the ſettlement where Mr. Mackenzie reſided eight years, conducting the concerns of the north-weſt company, whence he took his departure on both his expeditions of diſcovery; and the furtheſt to the north-weſt hitherto eſtabliſhed for carrying on the commerce in furs and peltry. The following is the ſtatement he gives of the mode adopted in tranſacting the buſineſs. "The flotilla of laden canoes, which leave lake de Pluie about the firſt of Auguſt, do not arrive here till the latter end of September, or the beginning of October, when a neceſſary proportion of the number is diſpatched up the Peace river, to trade with the Beaver and Rocky Mountain Indians. Others are ſent to the Slave river and lake, to traffic with the inhabitants of that country. A ſmall part of them, if not left at the fork of the Elk river, return thither for communicating with the Kniſteneaux; while the reſt of the people and merchandize remain here to trade with the Chepewyans. In the fall of the year, the natives meet the traders at the fort, where they barter the furs or proviſions which they have procured, then obtain freſh credit, proceed to hunt the beavers, and do not return till the beginning of the year; when they are again fitted out in the ſame manner, and come back the latter end of March, or the beginning of April. But they are now unwilling to repair to the beaver hunt until the waters are clear of ice, that they may kill them with fire-arms, which the Chepewyans are averſe to employ. The major part of the latter return to the barren grounds, and live during the ſummer with their relations and friends in the enjoyment of that plenty which is derived from numerous herds of deer. Yet perſons of that tribe who are moſt partial to thoſe deſarts cannot remain there in winter, and they are obliged, with the deer, to take ſhelter in the woods in that rigorous ſeaſon, during which they contrive to kill a few beavers, and ſend them by young men, to exchange for iron utenſils and ammunition. Till the year 1782 the people of Athabaſca ſent or carried their furs regularly to fort Churchill, Hudſon's bay, and ſome of them have ſince that time repaired thither, notwithſtanding they could have provided themſelves from the Canadians with all the neceſſaries which they required. The difference of the price ſet on

goods, here and at that factory, made it an object with the Chepewyans to undertake a journey of five or ſix months, in the courſe of which they were reduced to the moſt painful extremities, and often loſt their lives from hunger and fatigue. At preſent, however, this traffic is in a great meaſure diſcontinued, as they were obliged to expend, in the courſe of their journey, that very ammunition which formed its moſt alluring object." Such is the ſubſtance of the communications of the moſt intelligent writers upon this intereſting ſubject, ſeveral of whom were ably qualified to give it elucidation from having had ocular demonſtration of the facts they relate. But none of them attempt to detail the particular mode of intercourſe with the Indians, or the ratio of exchange or barter between them and the traders. This, which will be regretted by all who have read the very important information contained in their works, particularly in Mr. Mackenzie's voyages, may be accounted for thus: the writers were perſons intereſted in the trade, the lucrative returns of which formed a ſtrong inducement to give general information rather than narrate particular circumſtances, that, if developed, might have led to an injurious competition. Some idea, however, of the agio, or rate of exchange, as well as the manner of effecting it, has already been given in the account of the commercial relations between the Indians and the Hudſon's bay company. A further elucidation may be found in the following ſtatement, which, as a maximum fixed by government for the benefit of both parties, though occaſionally departed from, probably conſtitutes a general guidance or regulation for the trade.

In the year 1762 the governor of Nova Scotia, having conciliated the friendſhip of the neighbouring Indians, who had been converted to the religion and intereſts of the French, an act was paſſed by the provincial legiſlature to guard againſt the interruption of the provincial harmony, by fraudulent practices in perſons who trade with the Indians; and to oblige all ſuch to take out licences, and give ſecurity for their compliance with the regulations of the act. The ſtatute moreover eſtabliſhed a tariff of regulated prices, which were fixed as the ſtandard of the trading intercourſe between the white people and the Indians.

A pound of the beſt ſpring beaver, valued at 5*l.* was eſtabliſhed as the fixed ſtandard, by which all other goods were to be eſtimated, *viz.*

1¼ Of fall beaver 1 Otter ſkin 3 Sable or marten ſkins 6 Mink ſkins 15 Muſk rats, or muſquaſh ſkins 5lb. Of deer ſkins 10 Ermine ſkins	}	To be conſidered equivalent to 1lb. of ſpring beaver.
1 Large good bear ſkin	equal to	1⅗lb. of ſpring beaver
1 Red fox ſkin		½ ——
1 Black fox ſkin		2 ——
1 Silver fox ſkin		2½ ——
1 Large mooſe ſkin		1½ ——
1 Large cat ſkin, loup ſervie		2 ——
Seal ſkins, according to ſize, from 8*d.* to 3*s.* and 4*d.*		
6lb. Of feathers		1lb. of ſpring beaver.
1 Large blanket		2 ——
Rum, per gallon,		⅓ ——
Molaſſes, per gallon		⅖ ——
30lb. Of flour		1 ——
14lb. Of pork		1 ——
Stroud, per yard		1½ ——

And all other merchandize in proportion to theſe rates. From this, and preceding ſtatements, it will readily occur to the reader, that the profits of the fur trade are very large, and ſo they reaſonably ought to be, for the capital employed is great, and the returns peculiarly tardy. The agents are obliged to order neceſſary goods from England in the month of October, eighteen months before they can leave Montreal; that is, they are not ſhipped from London until the ſpring following, when they arrive in Canada during the ſummer. In the courſe of the following autumn they are made up into ſuch articles as are required for the Indians; they are then packed into parcels of eighty or ninety pounds each, but cannot be ſent from Montreal until the enſuing May; ſo that they do not get to market before the winter following, when they are exchanged for furs, which arrive at Montreal the next autumn, and from thence are ſhipped, to London chiefly, where they are not ſold, or at leaſt paid for, till the ſucceeding ſpring, or even as late as the month of June. Thus payment is made forty-two months from the time the goods were ordered in Canada; thirty-ſix after they had been ſhipped from England, and twenty-four ſubſequent to their having been forwarded from Montreal. So that from the time the goods have been bartered for furs, and theſe arrive in London, are ſold, and remittances made, full three years have elapſed. Conſequently, the merchant, allowing he has twelve months credit, does not receive his returns, to pay for thoſe goods, and anſwer the neceſſary attendant expences in procuring them, which are about equal to the value of the goods, till two years after they are conſidered as caſh, which renders this a very heavy buſineſs; the profits ought therefore to be at leaſt triple the profits of a trade where the capital is turned once a year.

The fur trade to the Canadians is nearly as valuable as their corn trade; it employs a great number of people, and a large capital. Beſides the expenditure it occaſions in Canada, the concern ultimately tends to the encouragement of Britiſh manufactures, for thoſe who are employed in the different branches of this buſineſs are enabled by their gains to purchaſe Britiſh articles, of which they otherwiſe muſt forego the uſe. The duty paid in England on furs and ſkins imported from Canada amounted, on an average of four years, ending 1806, to 22,053*l.* per annum. And further, we not only gain by thus being almoſt excluſively poſſeſſed of the commerce in furs and peltry, but alſo by the articles taken in exchange, which, it has been ſeen, are coarſe woollens, iron-ware, copper, and braſs utenſils, fire-arms, gun-powder, ſhot, and other manufactured articles. It has been pregnant with ſtill more general benefits, both to the important objects of ſcience and commerce; for the one has had new regions developed to its ken, by the reiterated exertions to extend the other. Thus what is generally conſidered, and in too many inſtances has been, congenial to the attainment of geographical information, in the preſent caſe has been productive of the moſt happy diſcoveries. Our Indian traders and wood rangers have explored ſeveral unknown countries, and found many nations and tribes to traffic with, far back in the interior of that vaſt continent, till at length they have penetrated to the great weſtern Pacific ocean, and opened a new way of intercourſe with Japan and China. It has developed more, for it has ſet at reſt for ever that long agitated, and juſtly deemed intereſting queſtion, reſpecting the exiſtence of a north-weſt paſſage, or communication by ſea, between the Atlantic and Pacific oceans. Mr. Hearne, a naval officer, but then in the ſervice of the Hudſon's bay company, in conſequence of ſome information received from the Indians, was ſent by the governor of Fort Prince-of-Wales on a journey of diſcovery in the year 1770. Having penetrated to the Frozen ocean at the mouth of the Copper-mine river, which by his ſtatement lies in nearly 72° north latitude, he

learned from converſation with the Indians, that the continent ſtretches aw from thence a prodigious way to the weſtward. By this journey it was aſcertained that any communication between the Atlantic and Pacific, if exiſting, muſt be beyond that high latitude. But ſince the conqueſt of Canada, more has been done in this way by a few ſpirited merchants, than had been effected for two centuries by the Hudſon's bay company, although their charter was principally, as it oſtenſibly ſtates, granted for that important purpoſe. The North-weſt company of Montreal, having been informed by one of their remoteſt agents, that the Indians had told him of a river flowing into a ſea, which was at no great diſtance to the northward; Mr. Mackenzie, one of the partners, left Montreal in the beginning of the ſummer of the year 1789, purpoſely to aſcertain the veracity of a communication ſo intereſting to ſcience and commerce. Attended by a few Indians, he traverſed partly in canoes, and partly by walking, the great extent of wilderneſs in which their poſts are eſtabliſhed, and proceeded beyond them down a conſiderable river, running north, till he actually arrived at the Frozen ocean, in which he ſaw ſome ſmall whales among fields of ice, and obſerved the riſe and fall of the tide. On an iſland, to which he gave the name of Whale-iſland, at the mouth of the river, to which alſo he affixed his own, he erected a poſt, near a few old deſerted huts, engraved on it his name, the number of perſons with him, the time they remained, and the latitude of the place, which was found by obſervation, 69° 14′ north. This voyage, or journey of diſcovery, and alſo that of Mr. Hearne's previouſly noticed, having developed the unfrequented regions of America, muſt be ſufficient to prove the utter impoſſibility of a navigable communication exiſting in any temperate part of that continent; and we might reaſonably expect to have no more conjectures or ſpeculations upon that ſubject, more eſpecially ſince the voyage of captain Vancouver in 1792, 3, and 4, who made a ſurvey of the whole north-weſtern coaſt of America, from latitude 39° 27′, north as far as the inlet, called Cook's river, and Prince William's ſound. Upon a very careful and minute inſpection of every creek and inlet of a coaſt, conſiſting entirely of creeks and channels, formed by an innumerable multitude of iſlands, he was enabled poſitively to aſcertain that there is no navigable paſſage between the Pacific and Atlantic oceans; unleſs there may be a poſſibility of ſailing through the generally frozen ſtrait between Aſia and America, and navigating the polar ocean, which bounds the unknown extremity of the latter continent. Mr. Mackenzie, in 1793, ſet out on another inland voyage of geographical and commercial diſcovery. In this ſecond expedition he directed his courſe to the weſtward, and after paſſing the higheſt land, and walking above 100 miles, he and his party re-embarked on a river running weſt, and plentifully ſtocked with excellent ſalmon, which conveyed them to an inlet of the Pacific ocean, where they ſaw porpuſes and ſea-otters, and obſerved a conſiderable riſe and fall of the tide. There, at a place previouſly denominated Caſcade Canal, by captain Vancouver, he painted upon a rock the words "Alexander Mackenzie from Canada by land, 22d July 1793." From theſe diſcoveries, and the fact having been aſcertained, that there exiſts no practicable north-weſt paſſage by ſea between Aſia and America, the practicability of a different kind of communication becomes an object of important conſideration. The Ruſſians, who firſt diſcovered, that along the coaſts of Aſia no uſeful and regular navigation exiſted, opened an interior intercourſe by rivers and lakes, through that long and widely extended continent to the ſtrait ſeparating Aſia from America, over which they paſſed to the territories of the latter. From this Mr. Mackenzie infers, that ſince the non-exiſtence of a practicable paſſage by ſea, and the exiſtence of one through the continent have been proved, the ſituation of our North American ſettlers has become nearly ſimilar to that of Ruſſia.

The trade in furs and peltry experience has proved, from its nature, cannot be advantageouſly carried on by individuals, for as a very large capital, credit, or both is neceſſary to conduct the concern with any proſpect of ſucceſs, it conſequently follows, as an eſſential point, that an aſſociation of men ſhould be formed, ſome of wealth to direct, and others of enterprize to execute, and ſo to act together in one common intereſt, and on ſuch principles, that the latter might ſucceed the former in continual gradation. The junction of ſuch a commercial aſſociation with the Hudſon's bay company, Mr. M. conceives would be a very important meaſure, which, if adopted, the trade might then be purſued with a very ſuperior degree of advantage, both in a private and public view, under the privilege of their charter, and would in fact prove the only method of completely fulfilling its ſtipulated conditions. He alſo obviates any objections to ſuch a plan, by conſidering it would be equal injuſtice to exclude either party from the option of ſuch an undertaking; conceiving, the right the one poſſeſſes by charter, as counterbalanced in the other caſe by prior poſſeſſion. And ſhould the company be adverſe to ſuch an union of intereſts, it would be a fair and reaſonable propoſal, upon a proper indemnification being offered, for government to oblige them to relinquiſh a right they refuſe to exerciſe, or to allow others the navigation of the bay to Nelſon's river; by which means the trade might be extended to the head of the Saſkatchiwine river, to the mutual advantage of Canada, and of Britain.

He further ſuggeſts, that by means of Port Nelſon river, which empties itſelf into Hudſon's bay, the Peach river, the Saſkatchiwine, that riſes in the rocky mountains, and the Columbia, which has its ſource on the weſtern ſide of the ſame; a communication by water might be formed nearly the whole length between the two great oceans, the Pacific and the Atlantic. By opening this intercourſe the Canadian merchants would be enabled to ſupply the natives of the interior with a larger quantity of uſeful articles, and at a reduced price. The enhanced value of which, and the difficulty of tranſporting them, will be eaſily comprehended, when the attendant circumſtances are taken into conſideration. The tract of tranſport occupies an extent of land from three to four thouſand miles, through upwards of ſixty large lakes, and numerous rivers, and the means of conveyance are ſlight bark canoes. And thoſe waters are interrupted by more than two hundred rapids, along which the articles of merchandize are chiefly carried on men's backs, and over a hundred and thirty carrying places, from twenty-five paces to thirteen miles in length, where the canoes proceed by the ſame toilſome and perilous operations. By the route propoſed moſt of theſe retarding circumſtances would be obviated, or greatly diminiſhed.

Since the diſcoveries on the north-weſt coaſt of America by captain Cook, one of the numerous advantages reſulting from the labours of that enterprizing circumnavigator was, the opening a new and extenſive ſource for procuring furs of the moſt valuable quality, and a new market for European commodities; the nature of which has been further elucidated by the exploratory voyages of captain Vancouver. By opening, therefore, the intercourſe recommended by Mr. Mackenzie, forming regular eſtabliſhments through the interior, and at both extremes, as well as along the coaſt; the entire command of the fur trade with North America might be

be obtained from 48 degrees of north latitude to the pole, except that portion of territory occupied by the Ruſſians. Such would be the ſpacious field for enterprizing exertion, and incalculable would be its advantages, if ſupported by the influence of credit and capital; means which Great Britain ſo pre-eminently poſſeſſes over other nations. Then would this country begin to receive ſome remuneration for the money it has expended in diſcovering and ſurveying the coaſts of the Pacific ocean, which at preſent are principally left to American adventurers, who, without regular ſyſtem, or adequate means to embark in the concern, and regardleſs of conciliating future confidence, look only to the intereſt of the preſent moment. Theſe having therefore collected all the ſkins they can obtain, and in whatever manner beſt ſuited to their means, proceed with them acroſs the Pacific to Canton, exchange them for the produce of China, and return with their wealth to their own country. Such adventurers, and many of them are very ſucceſsful in their concerns, would ſpeedily diſappear on the eſtabliſhment of a well-regulated trade; and nearly the whole traffic in furs muſt and would circulate through the channels of Britiſh commerce.

Some ſcheme or other, upon a grand ſcale, it is eſſential to adopt, if it be deſirable to preſerve the fur trade in the hands of the Hudſon's Bay and Canadian merchants. For ſince the ſetting up of the New York company, the diſcoveries on the north-weſt coaſt of America, and the finding what a profitable concern the ſale of fur was in the Chineſe and other eaſtern markets, the American merchants have made it an important ſubject of their ſpeculations. For the purpoſe of collecting information, and opening an intercourſe with various Indian tribes, an expedition was undertaken at the expence of the American government, by "a corps of diſcovery," as it was termed, under the command of captains Lewis and Clarke, belonging to the army of the United States. The voyagers, for it was performed greater part of the way in canoes, ſpent the years 1804, 1805, and 1806, in obtaining the object of their purſuit, which was, to find a paſſage by the Miſſouri and Columbia rivers to the Pacific ocean. The intention was fully anſwered by their aſcertaining the exiſtence of ſuch a practicable communication. By this means the people of the United States have obtained a fine clue to the north-weſt Indian tribes, and the river Columbia, with the adjacent bays and creeks, which abound with immenſe numbers of the ſea-otter, an animal that produces the fineſt and moſt valuable fur. Thus have they become poſſeſſed of the power of competition with the inhabitants of the northern ſtates ſubject to Britain; and are likely, if the Canadians ſtill continue to be circumſcribed by the tenacity of the Hudſon's Bay company, to outrival the Britiſh merchants in their own market.

See "Voyages from Montreal on the River St. Laurence, through the Continent of North America to the Frozen and Pacific Oceans, in the Years 1789 and 1793," by Alexander Mackenzie, eſq.; "Annals of Commerce, Manufactures, Fiſheries, and Navigation," by David Macpherſon; "An Account of ſix Years' Reſidence in Hudſon's Bay, from 1733 to 1736, and 1744 to 1747," by Joſeph Robſon; Vancouver's "Voyage round the World;" Gaſs's "Journal of a Voyage up the Miſſouri, &c.;" Umfreville's "State of Hudſon's Bay, and the Fur Trade;" "Letters from Canada, written during the Years 1806, 1807, and 1808," by Hugh Gray; Invoices of cargoes in the ſhips belonging to the Hudſon's Bay company; Invoices of cargoes of the ſhips employed in the fur trade from Canada; and reports of the reſpective ſales.

FUR, in *Heraldry*. See FURR.

FUR, in *Ornithology*, a name given by Bartholine to the LARUS *paraſiticus*.

FUR-*ſlice*, in *Agriculture*, a term employed in the northern parts of the iſland to ſignify the long narrow ſlice of earth turned up by the plough. See FURROW-*ſlice*.

FURA, in *Geography*, a ſmall iſland near the weſt coaſt of Scotland; five miles W. of Udrigill Head.—Alſo, a mountain of Africa, in Mocaranga, rich in gold; 30 miles from Maſſapa.

FURAJANNA Soo, a town of Africa, in Fooladoo. N. lat. 13° 16'. W. long. 7°.

FURANS, a river of France, which runs into the Iſere, near Romans.

FURBA, *Valley of*, one of the five diſtricts of the county of Bormio, in Switzerland. See BORMIO.

FURBISHER, a perſon who furniſhes or poliſhes arms, and gives them a brightneſs and luſtre.

In the general ſenſe of the word, it includes what we now call armourers and ſword-cutlers; in a more reſtrained ſenſe, it is appropriated to thoſe who clean and ſcour up old ſwords, guns, and halberds, and put them in order.

Among the officers of the Tower there is a furbiſher of ſmall arms, another of ſwords; and the like there is in moſt other armories of England.

FURBISHING, the act of cleaning, ſcouring, and poliſhing arms; as guns, piſtols, ſwords, &c.

The word is formed of the French *fourbiſſure*, which Hicks derives from *furben*, which, in the language of the ancient Franks, ſignified to clean and poliſh: though M. Huet chooſes rather to derive the French *foubir*, and *fourbiſſure*, from the Engliſh *furbiſh* and *furbiſhing*. Skinner obſerves, that ſome authors derive the Engliſh *furbiſh* from the Latin *furvus* and *fervor*; but for his part, he rather derives it from the German *farb*, colour; and *farben*, to dye, or give a colour.

Furbiſhing is principally performed with emery.

FURCA, FORK, in *Antiquity*, a kind of puniſhment, or rather an inſtrument of puniſhment, among the Romans. The form of the Roman furca is very obſcurely deſcribed by the ancients, and much controverted by the moderns. All we know for certain is, that it was of wood, and reſembled a fork; whence it is called, in writers, ξυλον διπλων διχερων διδυμον, that is, *lignum duplex, bicornutum, geminum*; a double forked, or horned, timber. Plutarch, treating of the furca, ſays, it is originally the piece of timber wherewith the beam of the waggon is upheld: he adds, that it is the ſame with what the Greeks call *apoſtates* and *ſterigma*; and the ſterigma is deſcribed, by Heſychius, as the forked piece of timber put under the yoke of the waggon.

From theſe accounts, Godwyn takes the furca to have been the beam of a waggon, to which the yokes are faſtened.

The puniſhment of the furca was of three kinds; the firſt only *ignominious*, was when a maſter forced his ſervant, for ſmall offences, to carry a furca, or fork, on his ſhoulders, about the city; confeſſing his fault, and warning others to beware of the like: whence ſuch ſervant come to be denominated *furcifer*.

The ſecond kind was *penal*; when the party, having the furca on his neck, was led about the circus, or other place, and whipped all the way.

The third was *capital*; the malefactor having his head faſtened to the furca, and ſo being whipped to death.

In after-times of the empire, when this ſort of puniſhment became interdicted, the form of the furca was changed, and made like our gibbets, or gallows. See CROSS.

FURCA, in *Geography*, a mountain of Switzerland, on the N.E. extremity of the Vallais, the aſcent of which is ſteep and difficult. A number of rugged and forked rocks, piled one above another, have occaſioned, it is ſaid, this chain to be called the "Furca." Near the ſummit, the height of which is eſtimated at 13,000 feet, between the Blaueberg and the Langnetz, a large body of ice ſupplies a torrent, which is probably one of the firſt ſources of the Rhone. The glacier of the Furca is an immenſe body of ice, extending at leaſt three miles in length, and near a mile in breadth between the Gleteherberg and the Satzberg, rocks more rugged, if poſſible, than any of the neighbouring mountains; it ſtretches from their foot, fills up the intervening chaſm, and reaches almoſt to their ſummits. The river Rhone is chiefly formed by this glacier: the ſmall torrent, already mentioned, being joined by ſeveral ſtreams, loſes itſelf under the vaſt arch of ice that forms the bottom of the glacier, iſſues conſiderably augmented, and is the great and principal ſource from whence the Rhone takes its riſe.

FURCA & *flagellum*, in our *Old Writers*, denotes the meaneſt of all ſervile tenures, when the bondman was at the diſpoſal of his lord for life and limb. "Ipſe tenet in villenagio ad furcam & flagellum de domino ſuo, &c."

FURCA, *and Foſſa*, in our *Ancient Cuſtoms*, *i. e.* gallows and pit, denoted a right or juriſdiction of puniſhing felons; *viz.* men with hanging, women with drowning.

FURCHE, in *Heraldry*, a croſs forked at the ends. See CROSS.

FURCONIUM, in *Ancient Geography*, a town of Italy, in Samnium, belonging to the Veſtini; at ſome diſtance S. of Amiternum: it was alſo called *Furconia*.

FURCULA, in *Anatomy*, the ſame with clavicula.

FURCULA, in *Geography*, a mountain of Switzerland; 13 miles W. of Chiavenna.

FURET, in *Zoology*, the *ferret* or MUSTELA *furo*.

FURFUR, in *Medicine*, ſignifying literally *bran*, in the Greek πίτυρον, has been applied to various excrementitious matters reſembling bran; more eſpecially to the little fragments of the cuticle which ſcale off under certain morbid ſtates of the ſkin, and are alſo called ſcurf, dandriff, &c. The term was alſo uſed by Hippocrates to denote a ſort of bran-like particles or ſediment in the urine; whence urina *furfurea*, *furfureum* ſedimentum, &c. From the ſame root we have

FURFURATIO, πιτυρίασις, a term uſed by Galen, and many ſubſequent writers, to denote certain ſcaly eruptions of the ſkin: it is uſed alſo to ſignify the falling off of ſcurfy ſcales in combing, &c. See PITYRIASIS.

FURHER, in *Geography*, a town of Hindooſtan, on the road from Agra to Oajein, in the pergunnah of Shajawulpour, which is divided from that of Schore by the river Parbutty.

FURIA, in *Zoology*, a Linnæan genus of the *Vermes*, poſſeſſing, according to that diſtinguiſhed naturaliſt, the following eſſential character: the body linear, equal, filiform, and ciliated each ſide with a ſingle row of reflected prickles preſſed cloſe to the body.

One ſpecies only of this genus is deſcribed, that bears the appellation of the infernal fury (*Furia infernalis*), a name very amply merited, ſhould the relations of its terrific powers, as delivered to us by Linnæus, be conſidered as ſufficiently correct.

This moſt extraordinary creature is deſcribed as an inhabitant of the vaſt marſhy plains of Bothnia and Finland, where it is reported to live among ſhrubs or ſedges, and crawling on thoſe plants, is occaſionally driven, or carried forward by the wind. Their progreſs, as may naturally be imagined, is ſometimes intercepted by man or animals, and when they happen to ſettle on any expoſed part which is not perpendicularly ſituated, they inſtantly penetrate the ſkin, and bury themſelves in the fleſh ſo deeply, as only to leave a black dot or point where they entered. This is ſoon ſucceeded by the moſt excruciating pains, inflammation, gangrene, ſwooning, and death; all which happens in the ſpace of a day or two; frequently within the courſe of a few hours, unleſs the animal be immediately extracted from the fleſh, and this muſt be effected with the utmoſt caution, by applying a poultice of curds, or cheeſe, or in more dangerous caſes, by carefully diſſecting between the muſcles where it had entered.

The above is the ſubſtance of that information which the writings of Linnæus affords us. This celebrated obſerver of nature was himſelf once attacked by this malady, and, as it appears, in imminent danger of his life, but, happily for the learned world, was reſcued through the hoſpitable ſervices of a prieſt. This occurred in one of his herborizations near the city of Lund in Sweden. The prieſt, perceiving at once the cauſe of his malady, undertook the arduous taſk of recovering him, and this he effected by lacerating the fleſh, and extracting a vermiform ſubſtance about half an inch in length, which he produced to Linnæus, aſſuring him at the ſame time that this was the true and ſole cauſe of his diſorder. Linnæus, notwithſtanding its injured appearance, conceived it to be a true vermes, and without doubt, yet feeble in body, and with his mind deeply impreſſed with a recollection of the agonies he had ſuffered, as well as the danger he had ſo narrowly eſcaped, very emphatically gave it the name of the infernal fury, as it ſeemed to poſſeſs in reality thoſe fatal powers which were attributed to the imaginary being ſo denominated by the ancients. At his return to Upſal, he made known this circumſtance in an academical theſis, and afterwards inſerted it in the "Syſtema Naturæ," under the name of Furia infernalis.

That the effects of this malady, from whatever cauſe it may ariſe, are truly diſtreſſing, and oftentimes attended with the utmoſt danger, can admit of no diſpute. All the inhabitants of Bothnia and Finland are aware of theſe effects; yet upon the whole we cannot ſuppreſs aſtoniſhment, if this diſorder be really occaſioned by ſuch an animal, that it ſhould be known only to Linnæus. Blumenbach and Muller are perſuaded no ſuch creature as that deſcribed does exiſt, and Boſc, who has very lately written on this ſubject, informs us, that it is generally concluded among the Swediſh naturaliſts that their illuſtrious countryman was in error: they admit that in the fenny parts of Sweden ſuch a diſorder is known to prevail in autumn, and it is acknowledged alſo that it excites the moſt excruciating torments, and often terminates in death, by occaſioning gangrene in the parts affected, unleſs an immediate remedy is applied. The apoſtume with which the wound or cavity is filled, they deſcribe as having a vermicular form, but deny that it is a worm, or any kind of animal; and the vulgar opinion is, that it owes its origin to a poiſonous matter injected into the fleſh by the ſting of an inſect, the family of which is not at preſent aſcertained. Others believe that Linnæus was in ſome manner impoſed upon, and conceive that the object preſented to him muſt be the larva of an inſect; or perhaps one of the Nereides, and which, from its dried and lacerated ſtate, deceived him. The latter idea we are hardly inclined to admit, ſince it is ſcarcely probable in our mind that this able naturaliſt could have been ſo far miſled, and, we might alſo add, ſo groſsly impoſed upon, though at the ſame time it muſt be admitted poſſible that ſuch an error might have ariſen from an accidental cauſe, and that without any deſign of impoſition on the part of his communicant.

In

In an academical tract, publiſhed by C. G. Hagen in the year 1790, under the title of "Diſſertatio de Furia infernali," its ingenious author has brought together the various obſervations that have been advanced by writers relative to the Furia infernalis, and this the curious reader will not conſult without advantage. We cannot forbear, however, in referring to this production, to caution the reader not to aſſume its concluſions with precipitation. In collecting together ſuch reports, the author acquits himſelf of a pleaſing, and indeed an uſeful labour, yet it ſhould be remembered that his views are evidently to eſtabliſh a fact acknowledged doubtful, namely, the actual exiſtence of this extraordinary creature, and that without, as it appears, being in any manner acquainted with it, except on the authority of others. The opinions of the many are againſt this concluſion, and we would ourſelves obſerve, without aſſenting to either opinion, that its non-exiſtence is more diſtinctly proved in the fruitleſs reſult of all the reſearches made ſince the time of Linnæus to diſcover a ſecond example of this worm, than its exiſtence can be demonſtrated by the ſubtility of argument. Every effort to obtain another ſpecimen has been, it appears, ineffectual, though it cannot admit of doubt that the ſubject itſelf has greatly intereſted the attention of the learned, and who, from the information they had previouſly obtained, and the frequency of this malady in the eaſtern parts of Sweden, would have been directed, we ſhould imagine, with certainty to the object in view.

When the very exiſtence of an animal is denied by a reſpectable authority, as is preciſely the fact with regard to the Furia infernalis, it deſerves our ſerious conſideration: for notwithſtanding the conſummate knowledge of Linnæus, its original deſcriber, he might, from ſome adventitious cauſe, be deceived; but it cannot be ſuppoſed an aſſertion, denying the exiſtence of ſuch an object, would be advanced without the moſt poſitive reaſons for that denial, or we ſhould at leaſt ſincerely hope not. At all events, we are perſuaded the fact is ſtill uncertain, and perhaps our judgment ought to be ſuſpended till the true cauſe of the malady it is ſuppoſed to occaſion be clearly determined to ariſe from ſome other cauſe, or that the diſcovery of another ſpecimen of the ſame worm ſhould remove all doubt reſpecting it.

FURIAN LAW, in *Roman Antiquity*, a teſtamentary law, ſo called from C. Furius, the tribune, by whoſe intereſt it was enacted. This law forbad any Roman citizen to leave by legacy above the value of one thouſand aſſes to any one perſon, and at the ſame time condemned the legatee to pay four times the ſum which was given him above what the law ſtipulated. See VOCONIAN *Law*.

FURIANA, in *Geography*, a river of Sicily, which runs into the ſea on the North coaſt. N. lat. 38° 11'. E. long. 12° 45'.

FURIES, *Eumenides*, *Diræ*, in the *Heathen Theology*, and *Poetry*, were infernal deities, ſuppoſed to be the diſpenſers of the divine vengeance, the puniſhers of wicked actions both here and hereafter, and the inflictors of terrors, wars, and peſtilence.

The furies were reputed the miniſters of Pluto, and the avengers of crimes. Strabo paints them clothed in long robes falling to their heels, but girt about the breaſt. They were three in number, TISIPHONE, MEGÆRA, and ALECTO. Theſe names, which import *rage*, *ſlaughter*, *envy*, &c. were perfectly applicable to them.

The poets ſpeak of great numbers of furies, ſome of whom were employed in tormenting criminals in Tartarus, or others wandering over the earth to tempt, or to puniſh the wicked here. Thus Virgil ſpeaks of the

"—agmina ſæva ſororum." Æn. vi. ver. 571.

But the three, above named, were ſuppoſed to exceed all the reſt in cruelty and malice, and the power of doing miſchief, and are called, by way of eminence, *the Furies*, and ſometimes the *Diræ*, a name peculiar to theſe three. They were three ſiſters, and born at one birth of the goddeſs of Night. Lycophron and Æſchylus ſay, they were the daughters of Night and Acheron. Others pretend that they owe their birth to Pluto and Proſerpine. Sophocles makes them ſpring from the Earth and Darkneſs; and Epimenides ſays, they were the ſiſters of Venus and the Parcæ, and the daughters of Saturn and Euonymus.

Patin, Spanheim, &c. will have it that we ſee theſe on the medal of the emperor Philip, ſtruck at Antioch, on whoſe reverſe are repreſented three women dreſſed as above mentioned, and armed with a key, and burning torches, poniards, and ſerpents.

Struvius, Antiq. Rom. Synt. cap. i. p. 182. adds, that the three furies may probably be no other than the triple Hecate, whom the ancients believed to purſue and torment the wicked in hell, on earth, and in heaven.

Some of the poets add a fourth fury called *Lyſſa*; a Greek word, ſignifying madneſs, or rage. Plutarch allows but of one fury, whom he calls *Adraſta*, the daughter of Jupiter and Neceſſity; who, according to him, was the ſole miniſter of the vengeance of the gods. Virgil ſeems to admit the Harpies into the number of the furies, and even calls them by that name. (Æn. l. iii. 252.)

The poets repreſent the furies as old, ſqualid, and meagre, with pale cheeks, having a kind of feveriſh fluſh on them, with eyes inflamed, their heads twiſted round with ſnakes, and furniſhed with whips and burning torches in their hands, to puniſh the guilty. Their attendants were terror, rage, paleneſs, and death. Thus ſeated round Pluto's throne, whoſe prime miniſters they were, they waited his orders with an impatience that marked out all the fury which they poſſeſſed.

The daffodil was ſacred to the furies, and ſuch as offered ſacrifices to them were crowned therewith. This we learn from Euſtathius, on the firſt book of the Iliad, p. 87.

Theſe furies were alſo called *Pœnæ*, Ποιναι, on account of the puniſhments they inflicted on criminals; as their denomination furies aroſe from the rage and madneſs which they threw into the conſcience. (Voſſ. de Idolol. lib. viii. cap. 18.) The Greeks called them *Erynnides*, *q. d.* ερις νε, contentio mentis, or becauſe, as Pauſanius remarks, ερινυειν ſignifies to fall into fury.

The Greeks called them *Eumenides*; the origin of which name is much controverted among the learned. The etymology that ſeems beſt authorized, derives it from ευμενης, *gentle*, *mild*; which was applied to them on occaſion of Oreſtes being abſolved of the murder committed by him on the perſon of his mother. Minerva, it ſeems, appeaſed and pacified the furies, ſo that they ceaſed to purſue him; upon which the Athenians ever after denominated them *Eumenides*.

But it muſt be obſerved, that, in truth, the Athenians called them by the ſame name long before Oreſtes time, as appears from the Œdipus of Sophocles. There was a temple in Athens, near the Areopagus, conſecrated to the Eumenides, whom the Athenians called *venerable goddeſſes*: Ariſtides, and the ſcholiaſt of Thucydides, ſpeak of this temple as erected in memory of the judgment of Oreſtes.

Goddeſſes ſo awful as the furies, we may naturally imagine, commanded particular homage. Accordingly they had temples in ſeveral places of Greece. But of all the temples dedicated to theſe divinities, there was not one of them, next to that built by Oreſtes in the Areopagus,

more

more noted than that which the ſame Oreſtes built in Arcadia. Theſe temples of the furies were a ſecure ſanctuary for thoſe who retired thither. Pauſanias ſays, that, after the death of Codrus, the Dorians, who were guilty of it, would all have been puniſhed with death by the judges of the Areopagus, if they had not avoided it by flying for refuge to the temple of theſe goddeſſes. Although the worſhip of the furies did not make ſo great a progreſs in Italy as in Greece, yet they were not neglected by the Romans. This we may conclude to be the caſe, if we admit the opinion of Cicero, that the goddeſs Furina was the ſame with the furies.

Beſides the Narciſſus, they uſed likewiſe in their ſacrifices branches of cedar, alder, hawthorn, ſaffron, and juniper; they ſacrificed to them ſheep and turtle-doves, as we learn from Œlian (de Animal. l. 10. c. 44.) and they uſed in their ſacrifices the ſame ceremonies with thoſe of other infernal deities. Pauſanias (in Arcad.) remarks, that in the earlier times the ſtatues of theſe goddeſſes had nothing different from thoſe of other divinities, and that the poet Æſchylus, in one of his tragedies, was the firſt who repreſented them with that hideous air, and choſe ſerpents that made them ſo dreadful, that the firſt repreſentation of his play proved fatal to many of the ſpectators. The deſcription given of the furies by this poet was followed, and it paſſed from the theatre to the temples. Henceforth they came to be repreſented as we have above deſcribed them.

FURIGELDUM, in our *Old Writers*, a mulct paid for theft.

FURINA, in *Geography*, a river of Cuba, which runs into the Spaniſh Main. N. lat. 20° 3'. W. long. 76° 10'.

FURINALIA, in *Mythology*, feaſts inſtituted in honour of Furina, the goddeſs of robbers among the Romans. They were celebrated on the ſixth day before the calends of September. The goddeſs Furina had a temple at Rome, and a prieſt called *flamen Furinalis*. Cicero repreſents this goddeſs as the ſame with the furies; and Turnebus, in his Adverſaria, defends this opinion, alleging that Plutarch, in ſpeaking of the wood conſecrated to Furina, where the younger Gracchus was killed, calls it the wood of the Erynnies, or of the furies.

FURLING Lines are ſmall lines made faſt to the top-ſails, top-gallant-ſails, and the mizen-yard-arms; ſerving to furl up thoſe ſails, *i. e.* to wrap and bind them up cloſe to the yard. The mizen has but one furling line, but all the reſt have two, one at each end. Thoſe that are uſed for the larger ſails are generally flat, and are known by the name of gaſkets.

FURLONG, an Engliſh long meaſure, containing the eighth part of a mile.

The Engliſh furlong is equal to 40 poles or perches, (the perch being 16½ feet) = 10 Gunter's chains = 1000 links = 110 Engliſh fathoms = 220 Engliſh yards = 440 cubits = 660 Engliſh feet = 7920 Engliſh inches = 132 paces = 176 Engliſh ells = 880 ſpans = 2640 palms, &c. In an old law-book, printed in Henry the VIIIth's time, we read, that ſix hundred feet, of five ſcore to the hundred, make a furlong.

In Scotland the furlong is equal to forty falls = 240 Scots ells = 1 $\frac{1}{7\frac{1}{5}}$ Engliſh furlong. In Ireland the furlong is = 1.2727 Engliſh furlongs.

Hercules is ſaid to have run a ſtadium, or furlong, at one breath.

Furlong is alſo uſed for the eighth part of an acre, or half a rood.

Furlong is ſometimes alſo uſed for a piece of land of more or leſs acres.

" Omnibus Chriſti fidel. Johannes Blunt de Eye, arm. —Dedit Thomæ Croft & Franciſco Lovel. arm. unum furlongum terræ arabilis continen. per æſtimationem quatuor acras, &c." Dat. 20. Jan. 3 Eliz. The furlong, as a ſuperficial meaſure, is generally 10 acres, according to the acre of different counties. The Engliſh ſquare furlong is = 10 Engliſh acres = 40 roods = 1600 ſquare poles = 100 ſquare Gunter's chains = 10,000 ſquare ſtaves = 1,000,000 ſquare links = 48,400 ſquare yards = 435,600 ſquare feet = 174,240 ſquare paces. See Measure.

FURLOUGH, in *Military Language*, a licence granted by an officer to a ſoldier to be abſent for ſome time from his duty. See Deserters.

FURMION, in *Geography*, a town of Iſtria; 18 miles E.S.E. of Umago.

FURNA, a ſmall iſland in the Grecian Archipelago. N. lat. 37° 42'. E. long. 26° 19'.

FURNACE, an utenſil, or veſſel, proper to contain fire, or to raiſe or maintain a vehement fire in, whether of coal or wood.

There are divers kinds of furnaces, of various forms, and for various uſes.

The domeſtic furnace, uſed in making confections, &c. is uſually of iron, or earth.

Thoſe uſed by the goldſmiths, refiners, &c. are much larger, and of a different ſtructure.

Thoſe wherein lime, bricks, &c. are burnt, are called kilns.

Furnace, in general, means a veſſel or place in which high, or long continued heat can be applied in chemiſtry, in the arts, and domeſtic economy, and theſe are either fixed or portable.

Furnaces are principally divided into two kinds, thoſe which act by the draught of a chimney and called *air* or *wind furnaces*, and thoſe in which the air is forced in by bellows and called *blaſt* furnaces. But before we give deſcriptions of the different furnaces uſed in various chemical and other operations, we ſhall give a brief outline of their general principles, firſt premiſing that furnaces commonly conſiſt of three diſtinct parts; a body, or cavity to contain the fuel, a chimney to carry off the heated air and ſmoke, and a receptacle under, and ſeparated from the body by a grate, and called the aſh-pit. Although the conſtruction of furnaces is a ſubject of the greateſt importance to thoſe employed in chemical and metallurgic operations, we yet do not find that any chemiſt or other philoſophical writer has given principles, or any thing like a theory, from which rules might be deduced for the conſtruction of a furnace of any kind, that ſhould with certainty fulfil its intention; and a perſon, wiſhing to build a furnace, has hitherto had no other guide than that of taking the exact dimenſions of ſome other furnace, that by mere gueſs has been ſo conſtructed as to act well. One fact we may uſe as a general rule, that is, that ſince the heat is generated by combuſtion, it muſt be the greateſt when the greateſt quantity of fuel is conſumed in the leaſt time, and when the fuel is in ſufficient quantity, the heat will be in proportion to the quantity of oxygen paſſing through the fire in a given time.

In ſuch a furnace as we have juſt pointed out, with a view to define the parts, if the fire be kindled, the air in that part will become ſpecifically lighter, and will therefore aſcend; the place of the aſcending air muſt be ſupplied from below, and if there be no opening below, but through the grate, all the oxygen which enters muſt contribute to the increaſe of the combuſtion.

Every increaſe of heat will give an additional levity to

the air, and for a certain length of time the heat will continue to increaſe till it arrives at its maximum.

The velocity with which heated air aſcends is as the difference of ſpecific gravity between that of the atmoſphere and the heated air. The principles on which the motion ariſing from a change of ſpecific gravity may be referred to the caſe of two weights hanging over a pulley. If they are of equal weight no motion is produced, but if one be increaſed, or the other diminiſhed, the heavy one will deſcend and the light one aſcend, with a velocity proportionate to their difference.

If the ſum of the weights be W and their difference P, then, according to Mr. Atwood's theorem, which he confirmed by experiment, the velocity at any point will be $\frac{P}{W}$ multiplied by the velocity which a body would acquire by falling freely through the ſame ſpace.

The riſing or falling of bodies in different fluids may be referred to the ſame calculation, by ſubſtituting their ſpecific gravities for the abſolute gravity of the weights.

Let 1 = the denſity of the ſurrounding air,

d = the difference of temperature between the ſurrounding and heated air in degrees of Fahrenheit,

P = the number of degrees of Fahrenheit required to double the bulk of a given quantity of air,

h = the height of the chimney,

S = the ſpace a body will fall through in a ſecond of time,

v = the velocity of the aſcending air: then the increaſe of bulk in the heated air will be $1 + \frac{d}{P}$, and the denſity, compared with the ſurrounding air, will be $\frac{P}{P + d}$. The difference of denſity will be $1 - \frac{P}{P + d} = \frac{d}{P + d}$, and the ſum of their denſities $\frac{2P + d}{P + d}$; then $\frac{d}{P + d} \div \frac{2P + d}{P + d} = \frac{d}{2P + d}$. This fraction, agreeable to Mr. Atwood's theorem, multiplied into the velocity a body would acquire by falling through h, will give the velocity of the aſcending air;

$S : 4S^2 :: h : 4Sh$; then $2S^{\frac{1}{2}}h^{\frac{1}{2}}$ will be the velocity a body would acquire by falling through h.

Hence $\frac{d}{2P + d} \times 2S^{\frac{1}{2}}h^{\frac{1}{2}} = v$, the velocity of the aſcending current.

In finding d, let the temperature at the bottom of the chimney = B; that at top T; and let the temperature of the air which enters at the grate be M: then $d = M - \frac{B + T}{2}$.

The above theorem will require an equation for the friction of the tube, which will be very great in chimneys made of brick. It is plain that if it were not for the friction of the tube, the velocity would be as the ſquare root of the height, all other things being equal.

In order to aſcertain how far the friction of the tube affects the ratio of the ſquare root of the height, I took (ſays the writer of this article) an iron tube of one foot long and two inches in diameter, having a funnel-ſhaped mouth, at the lower end, four inches wide, and about the ſame length. At the top of the tube was placed a ſmall paper fly, with its axis vertical, ſo that it might be turned by the riſing current, in a manner ſimilar to the fly of a ſmoke jack.

I found that a very ſmall change of temperature was capable of putting the fly in motion. And that keeping both my hands upon the outſide of the funnel, at the ſame time that there was free acceſs of air into its mouth, I had conſtantly about 45 revolutions made by the fly in a minute. Reckoning the difference of temperature, or d, 45° Fahrenheit, which was about the fact, it would give by the theorem above ſtated the velocity about $\frac{3}{5}$ths of a foot per ſecond, which was near the truth.

The fly was then removed and placed at the top of the tube, lengthened to four feet. The velocity in this inſtance by the theorem ſhould have been 75, but did not exceed five, ſo that the defect produced by the friction was .25. It would appear, therefore, that every increaſe of velocity, by increaſing the height of the tube given by the theorem, may be divided by two, to reduce it to experiment. For the retardation by the friction, and the acceleration of its riſing, are in the ſame ratio, that is, as the ſquare root of the height. If, however, the velocity be increaſed by the change of temperature, or as d, then the friction will be increaſed in a greater ratio; for the friction is as the ſquare of the velocity. Therefore, if the velocity be twice as great from increaſing d, the friction will be four times as great. Hence the height of a chimney cannot increaſe the power of a furnace only to a certain extent, ſince the friction, after a certain limit, would prevent the acceleration, and bring the velocity to an uniform motion.

By other experiments I found that the manner in which the air enters the mouth of the tube is of ſome conſequence. When the mouth of the funnel was held about two inches above the ſurface of a table, the current up the tube was hardly ſufficient to put the fly in motion, and it would not begin to move till the mouth was elevated four or five inches. If, however, one-half the funnel reſted upon the table, and the other over the edge of it, the fly went at the rate of 45 revolutions in a minute. When the funnel's mouth was covered with paper, having a hole in the middle equal to the area of the tube, 47 revolutions were produced; but when the whole mouth was expoſed about the ſame height above the floor, it produced 49 revolutions.

It appears, therefore, that when the air can aſcend freely and perpendicularly to the entrance of the furnace, it is to the greateſt advantage.

Since, agreeably to the nature of our theorem, the velocity of the current muſt depend upon the difference of temperature between the internal and external air, the air entering the furnace ought to be as cool as poſſible. A furnace, therefore, ſhould be ſo ſituated, that its air may be ſupplied from a cellar below, into which its aſh-pit ſhould terminate. This cellar ſhould be as ſpacious as poſſible, and the aſh-pit ſhould be at leaſt four times the width of the furnace, reckoning from the grate to the floor; but the higher the better, becauſe the air, as we have before ſtated, is ſupplied with ſo much more facility in a perpendicular direction.

The grate of an air-furnace conſiſts of a number of ſingle bars, having ſhoulders at each end, ſo that when they are laid ſide by ſide, bringing their ſhoulders together, the interſtices between the bars may be nearly equal to the breadth of the bars. The diſtance between the bars is here rather more than is in common uſe, but for producing great degrees of heat, this account will be found to anſwer in practice. The bars are merely laid upon two bearers placed in the brick work at right angles to the bars; one of the bearers being looſe for the purpoſe of ſliding backwards to let all the bars fall down with the fire. Without this contrivance,

trivance, after any proceſs is finiſhed, the fire would have to burn itſelf out, and it would be much more troubleſome to clean the furnace when it is choaked with ſlag.

The height of the fire-place muſt be ſuited to the purpoſe to which the furnace is applied. If it is a melting furnace, the height muſt be ſuch that the fuel may be about half the width of the furnace above the top of the crucible, the latter being raiſed about $\frac{1}{4}$th the width of the furnace above the grate.

The chimney of an air-furnace ſhould be as wide as the ſum of all the interſtices through which the air enters the fire, allowing nothing for friction; but as this is very conſiderable, at leaſt that ought to be double, ſo that the chimney ſhould never be leſs than half that of the furnace.

The height of the chimney is the next conſideration. In the preſent ſtate of our knowledge we have no exact rule for the height of chimneys of furnaces. Indeed it will depend upon ſo many circumſtances, that it would be difficult to give this ſtatement exactly; ſince, however, the height is limited by the friction, it will be important to avoid all thoſe circumſtances on which the friction depends. The principal of theſe are, the roughneſs and narrowneſs of the chimney. The velocity of the aſcending air will be inverſely as the width; and the friction will be as the ſquare of the velocity. It is equally certain that the friction will be much increaſed if the chimney be rough in the inſide, but more particularly when it is crooked, or when the air is interrupted by having to move in any other direction than that of a perpendicular one.

When, therefore, the chimney conſiſts of an upright priſm or cylinder, having its interior ſurface as ſmooth as poſſible, it muſt act to the greateſt advantage poſſible.

If the chimney be made of brick, thoſe ſides of the bricks intended to form the interior of the chimney ſhould be rubbed to make them ſmooth, and laid with fine well-tempered fire clay, that the interior ſurface may be free from cavities and other inequalities.

If the chimney conſiſts of iron lined with clay, it ſhould conſiſt of lengths of about two feet each. After each of the pieces are lined and well dried, but not hard baked, the inſide ſhould be ſcraped or rubbed, to give them greater ſmoothneſs. By this means the height of the chimney may be increaſed to advantage beyond the ordinary height; ſince the above pieces or lengths may be fitted together and ſeparated with the greateſt facility, and the maximum of height may be eaſily aſcertained by experiment.

Another very important circumſtance ought to be attended to in the conſtruction of chimneys. The air which is heated in paſſing through the fire ſhould retain its heat, if poſſible, till it clears the top of the chimney. Although this cannot be effectually accompliſhed, it may be effected as far as the non-conducting power of the materials of the chimney will admit.

Common bricks are very bad conductors, and conſequently not well adapted for chimneys. But ſome fire-bricks of looſe aggregation are ſtill better calculated to retain the heat.

The beſt method, however, of making perfect chimneys, is firſt to build one of very cloſe, ſmooth bricks, making the internal ſurface as above directed. This ſhould be ſurrounded with a ſecond chimney, leaving a cavity between the two about the breadth of a brick. This cavity ſhould be filled with powdered coak, or, what is better, powdered charcoal. The heated air would retain its original temperature much longer in ſuch a chimney, which would admit of its being carried higher, and increaſe the draught.

The chimneys of portable furnaces are generally made of rolled iron. Theſe chimneys carry off the heat ſo rapidly, that the height is very ſoon limited, and beyond that point becomes an evil. It has been recommended by Lavoiſier to make the chimney of a double iron tube, and fill up the cavity with powdered charcoal. By this means, however, the internal tube would become ſo hot as to be eaſily acted upon by the air, and by ſulphuring the fuel conſequently would ſoon be deſtroyed. If the cavity between the two tubes were to be filled with a ſoft compoſition of equal parts of lime, clay, and ſand, making the cavity between the tubes about half the width of the inner tube, an earthen tube would be formed, which would form an excellent chimney, even after the interior tube of iron was deſtroyed. The furnace itſelf, being lined to a proportionate thickneſs with the above compoſition, would make a portable air-furnace capable of producing the greateſt degrees of heat.

In thoſe air-furnaces, where the fire-place is required to be diſtinct from the chimney and open at the top, ſuch as *Plate* II. *fig.* 3, the chimney is required to be connected with the fire-place by an horizontal channel called a flue. This flue muſt always be conſidered as an impediment to the draught of a furnace, and ought never to be uſed but where the ſeparation of the chimney from the fire-place is abſolutely neceſſary. From the experiments above-mentioned, it will appear that the air of a furnace ſhould aſcend as perpendicularly as poſſible; hence a horizontal flue ought in all caſes to be avoided, and it will be equally evident that this evil will be ſtill greater when the air has to deſcend, as in the furnace *Plate* II. *fig* 3. In all furnaces, therefore, where the fire-place is intended to be ſeparated from the chimney, the flue ſhould be made to aſcend as much as poſſible by making an obtuſe angle with the ſide of the furnace inſtead of a right one, as in *Plate* I. *fig.* 1. Various opinions have been advanced relative to the width of the flue. When we conſider, however, that the flue is a part of the chimney, all opinions muſt give way, for if the flue is not as wide as the chimney the air muſt have to move with a proportionably greater velocity in that part, and in the ſame degree leſſen the draught of the furnace. Hence the flue ſhould be the width of the chimney as near as poſſible.

Although in ſtrictneſs all furnaces are air-furnaces, yet, as we have above ſaid, they are uſually diſtinguiſhed into thoſe where the air is forced through the fire by bellows, and thoſe where the air enters by what is called the draught of the chimney.

Theſe are again denominated either from their conſtruction, or the particular uſes to which they are applied, as will be ſeen in the courſe of this article. Generally ſpeaking, the furnaces uſed in chemical operations, and for melting and refining metals, are of the latter kind or air-furnace; and we ſhall now proceed to deſcribe the parts and particular uſes.

FURNACE, *Air*. An air-furnace, calculated to produce great degrees of heat, particularly adapted for a melting furnace of the fixed kind, and poſſeſſing all the advantages to be given to it, is repreſented in *Plate* I. *fig.* 1; *a* is the aſh-pit of the furnace; *b* the grate; *c* the fire-place; *d* the cover, which conſiſts of an iron frame filled up with fire brick. The cover ſlides ſideways to open the furnace; *g e* is in place of the flue of the common air-furnace, but here is made a part of the chimney *b*. The part *e f g* may be taken away without injuring the furnace, and the receſs may be employed for many purpoſes, ſuch as roaſting ſubſtances, fitting crucibles upon it before they are introduced into the furnace; and occaſionally a cupel may be ſet upon it, for the purpoſe of aſſaying metals, having at the ſame time a ſmall opening in the cover *d*, for the purpoſe of admitting air. This furnace will be found much more powerful in not having a contracted flue, and at the ſame time making an obtuſe

angle with the ſide of the furnace. From what has been previouſly obſerved, the high aſh-pit will contribute much to its action. It is alſo recommended that the chimney ſhould be double, and the interſtices filled with powdered coak.

Fig. 2. repreſents a ſection of a portable air-furnace, adapted to general purpoſes: *a b* is a frame of caſt iron ſtanding on three legs; *c* a diſh of rolled iron for the aſhes to fall into; *a o* the top of the frame, has a hole in the centre a little wider than the fire-place, into which the grate is fitted; *d* is a groove paſſing quite through the frame, a little wider than the hole in the middle, and immediately under the grate. Different pieces of ſheet iron are made to fit this groove, having different ſized openings for the purpoſe of regulating the draught. One of them, however, has no opening, and is intended to ſhut out the air entirely. The openings in theſe regulating ſlides being in the centre, the air will enter the furnace perpendicularly, and its paſſage will be much facilitated by the height of the grate from the floor, and by the air having a free acceſs on all ſides to the furnace.

i k is the fire-place; *e* the cover, conſiſting of either one round brick made on purpoſe, fitted into an iron frame, or of ſeveral pieces fitted into the ſame. The outſide of the furnace is made of rolled iron, lined with a compound of two parts clay, two of coarſe ſand, and one of lime. The chimney is alſo of rolled iron, and conſiſts of double tubes, *no* and *pq*, rivetted to the outſide of the furnace. The cavity between the tubes is filled with the above-mentioned compoſition. The other parts of the chimney, when it is required to increaſe its height, may be made in pieces of about two feet in length, conſiſting, like the parts attached to the furnace, of a double tube, and the cavity filled up as before directed. The inner tube muſt be a little ſhorter than the outer tube, ſo that the additional length of the outer tube may form the joint in putting the chimney together. A hole is made in the body of the furnace at *i*, and a ſimilar one on the oppoſite ſide, for the purpoſe of introducing a tube through the furnace, which is required in many experiments. A ſlit is alſo made in the furnace at *k*, for the purpoſe of introducing the neck of a retort. The hole and ſlit above-mentioned have correſpondent plugs made of the ſame ſubſtance as the lining of the furnace, by which theſe openings are cloſed when not wanted. There is another opening at *g* fitted by the plug *h*: this is uſed for the introduction of fuel when it is not convenient to introduce it at the mouth of the furnace. Occaſionally, alſo, a ſmall muffle may be introduced into it at this opening, the other end of the muffle reſting upon the part *s*.

The cover being removed, a ſand-bath mug may be introduced, ſimilar to that in Dr. Black's, *Plate* II. *fig.* 7.

When a retort is introduced, and the bottom does not happen to be ſupported by the fuel, it is liable to move, and ſometimes to be broken, by reſting entirely upon the neck. This inconvenience may be remedied, by paſſing a ſolid plug through the furnace at *i*. This plug may be made by coating a piece of iron with a compound of very pure clay and ſand, to render it as infuſible as poſſible, ſince it will be expoſed to the greateſt heat of the furnace. The middle of this ſupport muſt contain a receſs to receive the bottom of the retort. When all the openings are cloſed, and a ſlide introduced at *a*, having an opening equal to the width of the furnace, this furnace will be found a moſt powerful melting furnace; and, by introducing different ſlides, it may be employed where the moſt moderate heat is required.

The air-furnace repreſented in *Plate* I. *fig.* 3, is principally intended for enamelling and aſſaying in the cupel, where the excluſion of every thing but the air of the atmoſphere is particularly neceſſary: *a b* is an iron frame, ſimilar to that of *fig.* 2, having a groove at *d*, for the ſliding plates to regulate the draught, and a tray at *e* to receive the aſhes; *g a y o* is the body of the furnace, made of rolled iron, and lined ſimilar to that of *fig.* 2, leaving the ſpace *m n* for the fire-place; *g p* is a dome connected at *p* by a ſliding hoop, with the chimney *w*; *s* is a circular damper; *f* is a muffle, having a plug at *e*; *t* is the ſtrong earthen tube ſtanding upon the grate, having an opening, *t*, quite through it, which correſponds with a ſimilar opening in the bottom of the muffle. This tube alſo ſerves as a ſupport for the muffle; *x* is an opening through the coating of the furnace, correſponding with a ſimilar hole in the end of the muffle. The end of the muffle is made convex, ſo as accurately to fit the ſide of the concave fire-place. Hence, a current of air will paſs up the tube, *t*, into the muffle, which will eſcape at the opening, *x*, into the chimney *l*. This current can be regulated by the circular damper *q*. The plug, *e*, is only to be taken out to inſpect the proceſs, the damper, *q*, being at the ſame time ſhut to prevent the entrance of cold air into the muffle.

On each ſide of the dome are two openings, ſuch as *b*, having plugs to fit. Theſe are for the purpoſe of introducing fuel during the aſſaying proceſs.

The advantages of this furnace, for the purpoſe of aſſaying, are obvious, ſince it can be regulated to the greateſt nicety. When the current of cold air tends to cool the muffle, or the heat of the furnace is deficient, the damper, *q*, can be ſhut more or leſs; and if the heat is too great, that at *q* may be opened, and *s* ſhut to any degree.

This furnace may very eaſily be converted into a melting-furnace, or even to one for general purpoſes. The dome *g p*, and the muffle *f*, being removed, and a cap put upon the mouth of the chimney *w*, the furnace having a cover ſimilar to that of *fig.* 2: the plug, *y*, being removed, will form the flue, the opening, *x*, being of no conſequence, particularly when the damper, *q*, is ſhut; and a plug muſt be introduced at *e*, where the muffle was taken out. The chimney may be lengthened from the part *z* by pieces ſimilar to thoſe recommended in *fig.* 2.

An air-furnace, on the common plan, is repreſented in *Plate* II. *fig.* 2, in which *a c* is the fire-place; *c* the grate; *b* the cover; *d* the flue; and *e* the chimney. This furnace differs from the air-furnace already deſcribed only in the conſtruction of the flue, and the aſh-pit.

A fixed air-furnace, invented by Mr. Knight, is ſhewn in *fig.* 3: *a b* is the fire-place; *b* the grate; *c* the entrance for the air under the grate; *e* is the flue; *f* a cavity or chamber, for the purpoſe of baking crucibles, and other uſes; *y* the paſſage for the air into the chimney *h*; and *i* is a ſliding damper. Although this furnace poſſeſſes great conveniences, it is not calculated for producing the greateſt degrees of heat, ſince the air muſt meet with much obſtruction in its paſſage from the fire-place to the chimney. *Fig.* 4. is a furnace invented by Mr. Muſhet, intended as an experimental furnace for the purpoſe of aſſaying ores, &c.: *a b c d* is a cylinder of caſt iron, lined with fire-bricks, ſo as to conſtitute the fire-place *e f*; *y* is the grate having a receſs in the middle for the reception of a crucible ſtand; *s* the aſh-pit; *o* is the flue; and *g* the cover: *h i* is a rod of ſteel faſtened into the bottom of the caſt iron cylinder at *h*, and having at the other end an index *i k*, fitted to the arc *q r*, which is attached to the cylinder. When the furnace is uſed, the exceſs of expanſion of the ſteel rod above the caſt iron cylinder will give motion to the index, and if the arc be graduated, ſo as to correſpond with Wedgwood's pyrometer, the degree of heat, in any experiment, will be known. In order to prevent the ſteel rod, which is poliſhed, from oxydation, it is incloſed in a tube of

iron,

iron, and the cavity filled up with powdered charcoal. The fire-place, from the grate to the cover, is three feet; the diameter at the grate ten inches, and at the top nine inches. The height of the chimney, the inventor recommends, ſhould not be leſs than thirty feet, and the width nine inches throughout.

Although this furnace has not been generally adopted, the thought is very ingenious, and, no doubt, practicable, to a certain extent. The ſcale would moſt likely require to be altered from time to time; firſt, from the change in the expanſibility of the ſteel rod; and, ſecondly, from the increaſe of the conducting power in the bricks. Theſe objections may be much obviated by attending to theſe changes. At all events, the pyrometer will enable the operator to find the relative heat, ſhould it even fail in meaſuring the abſolute degrees, which will certainly be a great acquiſition.

Dr. Black's reverberatory air-furnace is ſhewn in *Plate* II. *fig.* 1: *a b* is the fire-place; *b* the grate; *c* the cover; *a e* is an horizontal cavity through which the flame reverberates, and paſſes up the chimney *l*; *d* is a door for introducing the materials to be operated upon.

This furnace is uſed for roaſting various ſubſtances, ſuch as the ores of metals, for the purpoſe of expelling their volatile matter. It may be alſo employed for the cupellation of metals, the door *d* being a little opened for the admiſſion of atmoſpheric air.

Fig. 5. is a repreſentation of Mr. Knight's portable air-furnace; *a b* is the fire-place; *b c* the aſh-pit, which is cloſed on every ſide, excepting at the regiſter door, where the air is admitted; *o* is an opening for the reception of fuel; *e* is a receſs for the neck of a retort. *Fig.* 9. is a dome fitting the top of the furnace, to which the tube *fig.* 10. is connected, which unites with another tube inſerted into a common chimney. *Fig.* 8. is a ſand-bath, which is uſed in the abſence of the dome, and, like it, is connected with the tube 10.

This furnace is made of rolled iron, and lined with an earthy compoſition. *Fig.* 6. is a perſpective view of Dr. Black's portable air-furnace, which, but for its confined aſh-pit, has not as yet been improved upon: *a b* is the fire-place; *b c* the aſh-pit; *e* a ſliding door for the admiſſion of fuel, &c.; *d*, another door for the ſame purpoſe, and alſo for the introduction of a muffle. *Fig.* 11. is a cover, and *fig.* 7. a ſand-bath; *f* is a chimney, which is lengthened by pipes of rolled iron, or connected by the ſame with another chimney. This furnace, like the laſt, is made of rolled iron, and lined with clay and ſand.

Another air-furnace, of great power, and very convenient for operations, has been conſtructed and employed by Mr. Muſhet in his numerous and valuable experiments on iron and ſteel, a portion of which he has communicated to the public through the medium of the Philoſophical Magazine: he has obligingly furniſhed us with the drawing and deſcription. *Plate* III. *fig.* 1. is the ſection of an aſſay or melting, and annealing, and alſo a ſmall reverberatory furnace for fuſing in very high heats with the flame of pit-coal. A is the aſſay-furnace; B the reverberatory furnace; and C the annealing, or cementing-furnace.

The aſſay-furnace is caſed in caſt iron, with a flanch projecting inward, the breadth of a brick, and about half an inch more, which ſerves inſtead of bearers for the bars. (See *fig.* 2. at D.) Upon this flanch the brick-work is reared; it ought to be of good fire-bricks on the bed; the furnace is nine inches ſquare; total height 27 inches; from the top of the flanch, to the bottom of the flue, the interval is 18 inches; the flue is four inches high; the height above is five inches; flue ſeven inches long, and keeps opening into the chimney, as may be ſeen in *fig.* 3, at E. If the chimney is under 25 feet in height, a larger flue is requiſite; and if beyond 35 feet, a ſmaller flue will throw the heat more regularly through the furnace. In general, however, more harm enſues from too ſmall, than from too large a flue. G is the floor-line, and alſo repreſents the edge of a grate which covers the aſh-pit, which is better ſeen in the ground-plan, *fig.* 3, and in *fig.* 2, at H. This grate lies nine inches from the bars, leaving an open ſpace for the admiſſion of air; it projects 24 inches outwards, and ſerves the operator to ſtand upon.

II, in *figs.* 1 and 2, is the aſh-pit; in *fig.* 3, which is a ground plan of the chimney and furnaces, C is the annealing, or cementing-furnace, in which the crucibles are annealed, or baked, to a bright red heat, and from thence introduced, along with the matter to be operated upon, into the aſſay-furnace. It alſo ſerves inſtead of a cementing-furnace, being eaſily made to produce a heat of 100° of Wedgwood: it may be made of any ſize, from 9 to 14 inches ſquare, a 9-inch chimney being ſufficiently wide to the extent of an 18-inch furnace.

The chimney to each furnace is carried up five feet perpendicular; they then gradually incline to the centre opening, which they enter about twelve feet above the flues: L, L, L, are dampers: from the grates of this aſſay-furnace, to the top of the chimney, the interval is 33 feet.

This furnace has melted 400 grains of malleable iron in ten minutes; and half a pound from lumps in 40 minutes. If the materials to be operated upon are prepared with judgment, any experiment, to the extent of half a pound of matter, may be performed in half an hour, and leſs quantities in much leſs time. When approaching to its higheſt heat, a Stourbridge clay crucible (which drop in 168 of Wedgwood,) will diſappear in 15 minutes, from the time that it is put in. The firſt five bring it to 140° of Wedgwood, at which caſt iron boils. Steel boils in it at 162°, and malleable iron boils at 170° to 172° of Wedgwood. It is probable, however, that the advantages of this furnace do not reſult from the height of the chimney, (which is not great,) or from the ſize of its opening; more, it is likely, depends upon the flue; the opening of the grate bars; the ſize of the fuel; and particularly the feeding of the fire.

FURNACE, *Almond*, or *Alman*. This is alſo called a ſweep, and is uſed for ſeparating metals from cinders, ſlag, broken teſts, crucibles, &c. See SWEEP.

FURNACE, *Aſſay*. The furnaces above deſcribed may all be uſed for aſſaying or cupelling, ſee *Plates* I, II, III.

FURNACE, called *athanor* or *tower* furnace. This was a conſtruction of air-furnace, calculated to preſerve an equable degree of heat for a conſiderable length of time; it was much employed by the alchemiſts and chemiſts of the laſt and preceding century in their tedious and repeated diſtillations, calcinations, &c. but is not at preſent in uſe.

FURNACE, *Balling*. See IRON.

FURNACE, *Bellows* or *Blaſt*. Having given an account of the principles, and deſcribed the varieties of air, or draught furnaces, we ſhall give ſome account of thoſe furnaces which are ſupplied with their air by mechanical means, and are called blaſt-furnaces. This part, however, will not compriſe thoſe on the large ſcale for ſmelting iron, as that ſubject has been amply treated under the article BLAST-*Furnace*. We ſhall, therefore, confine ourſelves to the ſmaller blaſt-furnaces employed in chemical experiments requiring great and ſudden heat.

It will appear, from what has been obſerved reſpecting the principles of furnaces, that if the aſh-pit of a common air-furnace were made perfectly cloſe in every part, excepting through the grate, and an opening into the aſh-pit into which the nozzle of a pair of double bellows may be in-

ſerted,

ſerted, a blaſt-furnace would be found differing from an air-furnace only in the mode of forcing the air into the fire. Indeed its action would be ſo ſimilar to that of an air-furnace, that it might for moſt purpoſes anſwer the ſame end.

The blaſt-furnace for philoſophical experiments was much improved by the ingenious Dr. Lewis, who fitted up a black-lead crucible for this purpoſe. The pot choſen ſhould be of the largeſt ſize, and if a cover or dome, or an additional part be wanted, another pot with a portion of its lower narrow part ſawed off makes a very convenient one. A round plate or ſlip ſawed off from the ſolid part of the bottom ſerves very commodiouſly both for a grate and for a ſupport to the crucible; eight or nine holes, about three quarters of an inch in diameter, are bored round the outer part of the plate for the tranſmiſſion of the air forced in by the bellows, which holes are made to widen downwards to prevent their being choaked up by pieces of the fuel. The air was forced in by bellows by an aperture on the ſide of the pot.

In operations which require a conſiderable degree of concentrated heat, it has been propoſed to impel a number of flames into one point by ſtreams of air driven from different parts of the circumference of the fuel to the middle by means of ſeveral bellows placed round the furnace. But a number of bellows being incommodious, Dr. Lewis has contrived to multiply the ſtream of air from one bellows. The pot which ſerves as a furnace for this purpoſe has a number of holes bored at ſmall diſtances in ſpiral lines all over it, from the bottom up to ſuch height as the fuel is deſigned to reach to.

The crucible is placed on a proper ſupport in the bottom; and the holes are obliquely directed towards the crucible, ſo that the impelled heat plays in a kind of ſpiral upon its ſurface. The pot which ſerves for the blaſt furnace already deſcribed, with an iron ring at the top, receives this perforated pot ſo far, that all its holes are within the cavity, which cavity has no other outlet than the round aperture for the bellows; and therefore the air thus blown in will diſtribute itſelf through the perforation of the inner pot.

Mr. Arthur Aikin has conſiderably improved upon this plan of Dr. Lewis's, and the following is a deſcription of his furnace, as publiſhed in the Philoſophical Magazine.

Plate IV. *fig.* 3. is a view of a ſection of this furnace. It is formed of three black-lead crucibles. The 1ſt, *a*, is a crucible cut off near to the bottom, leaving a portion of the internal cavity; the 2d, *b*, is what contains the fire and the crucible. The bottom of this crucible is perforated with holes for the admiſſion of air, as ſhewn at *fig.* 4, which is blown into the cavity in the baſe part *a*, by double bellows. The ſtand of the crucible has a projecting part which fits a hole in the bottom of the crucible *b*, in order that it may ſtand more firmly (ſee *fig.* 5.); *c* is a third crucible ſometimes inverted upon that of *b*, when the fire requires to be heaped up higher, or to keep off the glare of light. This has a hole in the ſide to let out the air, and another into the bottom laterally, for the purpoſe of introducing an iron inſtrument to lift it on and off.

This furnace is particularly adapted for a lecture room, ſince its fire can be raiſed to its full heat in a very little time; at the ſame time it is capable of producing a greater heat than almoſt any other furnace.

Mr. Aikin has adapted this furnace to experiments with the cupel, by having a crucible with a hole through the bottom, and a ſtand having a correſponding hole through it, communicating with the cavity in the part *c*. In the inſide of the crucible are ſeveral projections forming a ſhoulder or flange to ſet the cupel upon. An earthen tube is fitted into the cover extending obliquely out of the mouth of the furnace; this ſerves to look down for inſpecting the proceſs.

Several kinds of ſmall blaſt furnaces are alſo uſed in the arts, particularly that uſed in melting pig iron for the purpoſe of caſting. This furnace is called a cupola, and will be deſcribed under iron. See IRON.

FURNACES *for making Colours*, are thoſe for ſubliming cinnabar or ſulphuret of mercury for making vermilion; for ſubliming ſulphuret of arſenic for making king's yellow; for calcining blood for making Pruſſian blue, ochre, &c. &c. For their conſtruction and uſe, ſee the arts, and the different articles in this work.

FURNACE *uſed for enamelling Pictures*. The extreme delicacy which is neceſſary in the proceſs of firing or burning in the colours in enamel painting, renders the conſtruction of the furnace an object of the utmoſt importance to the artiſt, whoſe labours are liable to be irrecoverably loſt by the ſlighteſt miſmanagement of the proceſs, or error in the formation of the furnace.

We are enabled, through the kindneſs of Mr. Bone, of Berner ſtreet, London, enamel painter to the king and prince of Wales, to preſent our readers and artiſts of this claſs with a drawing of the furnace which he has employed for firing his moſt celebrated productions, and which, we may ſafely ſay, have not been equalled either for the richneſs of colour and accuracy of deſign, or for the ſize to which he has extended the paintings on enamel, which were formerly confined to the moſt minute ſubjects. The lower part of *Plate* V. contains theſe drawings, which are two vertical ſections taken on planes perpendicular to each other; the ſame letters of reference applying to both. A repreſents the fire grate extended over the aſh-pit, B, of the furnace; the fire door at C for the admiſſion of the fuel is placed at the back of the furnace or ſide oppoſite to that where the operator is ſtationed, and in a ſeparate room: this is intended that the ſmoke, which will at ſometimes iſſue from the mouth of the furnace, may not endanger the pictures. The room, therefore, where the operation is performed, has no connection with the fire, ſo that the whole may be conducted without duſt or ſmoke. The pictures are placed in a muffle E, which is open only at one end; it is ſupported upon three ſmall arches, F, F, F, of brick-work extending acroſs the furnace; the ſpaces between theſe form three flues, which convey the flame of the fuel beneath the muffle. The mouths of theſe flues are ſhewn by the three dark ſquares *fig.* 11; they then turn up over the arched roof K, of the fire-place, and under the muffle between the arches F, F, F, at the commencement of theſe flues ſhewn by dark ſquares in *fig.* 11, and marked *a* in *fig.* 10. The flame divides, and a part proceeds over the muffle at *b*, being reverberated upon it by the arched roof of the chamber in which the muffle is ſituated. After paſſing over and under the muffle, the two currents of flame eſcape together to the chimney N, through three flues *d*, which are beneath an iron chamber H, called the annealing oven. In this four ſhelves are fixed to contain the articles which are to be annealed, previous to being introduced into the muffle. This is done through the open end which is expoſed at *e* to the open air, the junction of the muffle with the wall of the furnace being made by fire clay inſerted between them. Before the mouth of the muffle an iron plate, *f*, is placed ſupported by brackets: this, together with the wall of the furnace, forms a table to ſupport the picture when it is withdrawn from the muffle for examination. The muffle is made of fire clay in one piece, but it is very difficult to obtain materials which will withſtand the heat when in ſo large a maſs without cracking, which the beſt that can be procured

will

will do; frequently it, however, is not a very material defect, if a ſmall crack takes place at the upper part, as it begets a confidence that the muffle will not crack any further, owing probably to the unequal contraction of the parts of the muffle having liberty of action.

The operation of burning in the colours of a painting, or, as it is technically termed, *firing*, is conducted in the following manner: the picture painted, and prepared as deſcribed in our article PAINTING *in Enamel*, is placed upon a planch or flat piece of fire-ſtone, with a ſmall quantity of whiting between them, the uſe of which will be explained hereafter. Theſe are put into the loweſt ſhelf of the annealing oven H, and the door of the oven cloſed to prevent the entrance of duſt. The fire is now lighted on the grate, and after burning from three to four hours, according to the ſtate of the weather and direction of the wind, the muffle acquires a vivid white heat, and of ſimilar appearance in all parts: when this happens it is judged proper to begin firing; the pictures in the oven in the mean time have gradually acquired ſuch a heat as to be in no danger of cracking from the change of heat on entering the muffle; the planches have uſually reached a low red heat by the time the muffle is properly hot; and it is ſuppoſed that the oil uſed in mixing up the colours is nearly all evaporated, the painting exhibiting a very dull and faint appearance. It is proper that the door of the annealing oven ſhould not be too cloſe, that the vapour from the oil may readily eſcape.

The planch and picture upon it are now removed from the annealing oven by an iron fork, *fig.* 7, uſed in a manner ſimilar to a baker's peel, and introduced into the muffle: the doors are ſhut cloſe; the operator now looks through a ſmall hole in one of the doors, furniſhed with a ſliding cover, and attentively watches the picture; he ſees it gradually heat till it acquires the ſame colour as the muffle; the ſurface of the picture is then obſerved to aſſume a gloſſy appearance, ariſing from the fuſion of the enamel; at firſt this commences at the farther part of the muffle, but extends itſelf, with aſtoniſhing celerity, over the whole ſurface, if the operation is well conducted. The picture is now withdrawn from the muffle upon the table before its mouth, and examined before a ſtrong light, if every part is equally gloſſy; if not, it is returned to the muffle; in this ſtate the picture and planch only exhibit a maſs at a white heat; no traces of painting or colour can be diſcovered, and the whole judgment muſt be formed from its appearing equally fuſed in every part of the ſurface.

The fuſing being now completed, the picture is returned to the annealing oven; and the fire being put out by taking away the bars of the fire, the whole furnace cools gradually together, the picture remaining in the oven ſome hours before it is removed to paint again upon it. The operation of firing a picture requires to be performed from twelve to twenty-five times, according to the tints required, and the nature of the picture: the pictures are liable to crack whilſt in the muffle, an accident that cannot often be repaired, in which caſe the labour of painting is all loſt. The principal precaution againſt this is to proportion the flues in ſuch a manner that the annealing oven ſhall always be of ſuch a temperature that the pictures taken from it, and introduced into the muffle, may not experience ſuch a change of temperature as to fly. In Mr. Bone's furnace this is ſo well regulated, that he ſeldom finds his paintings crack in the firing, though it coſt him many ſevere diſappointments before he obtained this perfection by repeated trials: this diſpoſition to crack appears to depend almoſt as much upon the plate and enamel as the conſtruction of the furnace, and it is no proof becauſe a painting ſtands the firſt firings well, that it will not fly in the ſucceeding. Enamel pictures are nearly all liable to cockle or warp in the firing, in a greater or leſs degree, though this may be obviated ſo far, by great care in the preparation of the metal plate, as to be no ſerious detriment to the effect of the pictures: the method of preparing theſe plates is explained in the article ENAMELLING. For an account of the colours, and art of painting, ſee PAINTING *in Enamel*, which is a ſubject requiring long experience, to be added to the uſual knowledge of a painter, as the colours are in fact produced by the firing, being very different in appearance when laid on, and without any of the brilliancy for which this ſpecies of painting is diſtinguiſhed The artiſt muſt judge concerning the effect which his painting will produce by his recollection of the change of each colour, and its combination with others, inſtead of being able to examine it conſtantly by its appearance: but it is eſſential to the perfection of enamel painting, that all the colours employed ſhould blend together in the firing, and at the ſame heat, or ſome would be too much burnt before others were properly fuſed; and they muſt be of ſuch a nature as not to emit any vapour when in the fire, as this would produce bubbles in the ſurface, and deſtroy the effect of the painting.

As the colours at preſent known which will ſtand theſe teſts are but few, and require compounding together to produce the various tints, it is an additional reaſon why none can be admitted but ſuch as are acted upon in a ſimilar manner by the fire. It is conjectured that the crack in the muffle, being found rather to improve than leſſen the effect, may ariſe from a minute draught which will take placethrough the muffle, carrying off any vapours proceeding from the oil, which may remain in the colours after annealing, or other cauſes, which vapour, if confined to the picture, might be detrimental to the colours. As the generality of enamel plates are made with the ſurface convex, it becomes neceſſary, when they are large, to ſupport the centre of the plate from ſinking, which they are very liable to do when in a ſtate of fuſion. To prevent this accident, the planch muſt have a bed of powdered whiting laid upon it, with its ſurface made to fit the concavity of the enamel plate as nearly as poſſible, carefully avoiding all preſſure upon the plate, leaſt it ſhould receive any ſtrain. If this operation is nicely conducted, the plates may be made to keep their ſhape much better than by any other means that have as yet been deviſed.

FURNACE *for enamelling watch Dial-plates.* This furnace, though very ſimple in its conſtruction, differs from all the others we have deſcribed in not having any bars or grating for the admiſſion of air to the bottom of the fire; the only paſſage for air being through or under the muffle, which in this kind of enamelling conſiſts only of a ſimple arch of clay without either bottom or back.

This furnace is ſingularly adapted to the purpoſe for which it is uſed, as a very intenſe heat is obtained with a comparatively ſmall quantity of fuel, in addition to which the work may be brought almoſt in contact with the coals without receiving any injury from their dirt; clearneſs in this kind of enamelling being very juſtly conſidered one of its greateſt perfections. *Fig.* 1. of *Plate* V. *of Furnaces*, repreſents a front elevation; A, A, are two piers of brick work, upon which reſt the arch B, covering the aſh, or coak-pit, C. From each ſide of theſe piers project the three bricks D, D, D, which ſupport the hearth, or iron plate, E; another plate of caſt iron lies juſt beneath this, which ſerves for the bottom of the furnace, and which may be ſeen in the ſection at F, *fig.* 2. Upon this plate of iron ſtand the Welſh lumps, G, G, forming the interior ſides of the furnace; the one which forms the back may be ſeen at G,

fig. 2.

fig. 2: the brick-work is then carried upon each ſide over the piers, and bound together by the iron bar H, which likewiſe ſerves to ſupport the brick-work over the front, in which is fixed the regiſter, or damper, I. When the furnace is completed thus far, the flue may be carried up to a convenient height, or turned into one already formed.

To give the reader a clear idea of the method of uſing this furnace, as well as the way in which the fuel ſhould be placed, we have given, *fig.* 2, a vertical ſection through the line C I, perpendicular to the front; and that the parts in each may be compared, we have uſed the ſame letters of reference as far as the parts could be ſeen in each figure.

When the fire is to be made up for uſe, the muffle is to be placed in the furnace; one end reſting on the iron ſupport, as ſhewn at K, *fig.* 1, and the other end is to be kept level with the front by putting a piece of coak under each ſide. The ſpace on each ſide is then to be filled with ſmall pieces of coak, and at the back of the muffle ſmall coak muſt likewiſe be put in till it reaches about half way up the end. A ſolid piece of coak muſt then be ſelected, which muſt be large enough to cover the end of the muffle, and upon this a ſecond piece muſt be placed to ſupply the place of the firſt when that is burned away. The ſpace then immediately above the muffle muſt be filled with middling ſized pieces of coak, carefully building it up in the front, ſo as to keep it even with the ſides G, G. The door, as ſhewn at *fig.* 3, is then to be placed in the front, preſſing it cloſe up to the ſides G, G. To light the fire, nothing more is neceſſary than to fill the ſpace under the muffle with red-hot charcoal, and by drawing the damper a good way out the fuel will ſoon be alight all over. In *fig.* 2. it will be found that we have endeavoured to ſhew the poſition of the fuel placed in the order of our deſcription, with a ſection of the muffle ſhewing the height of the charcoal which lies at the bottom when the fire is in a ſtate fit for uſe. For we muſt here obſerve that it will be always neceſſary to beat that pretty ſmoothly down, that the apparatus which the dial lies on may be placed ſteadily upon it.

As it would be difficult in this figure to ſhew the poſition of the dial-plate in the fire, we have given, at *fig.* 8, a ſection of the apparatus as it is placed under the muffle; *a* being the dial-plate; *b b*, the ring; *c*, the planch; *d*, the turner. In uſing theſe, the turner is firſt placed ſteadily upon the bed of charcoal, and the dial, being placed upon the ring, is laid as nearly as poſſible in the centre of the planch, which is conveyed under the muffle, and placed upon the turner with the ſpring tongs, as ſhewn at *fig.* 6. When one ſide of the plate is nearly melted, the planch may be turned round by a ſlight touch with the tongs, till the whole dial is completely fuſed all over, when it muſt be withdrawn from the furnace, and placed juſt in the front of the muffle to cool gradually.

Fig. 4. is an end elevation of the muffle placed on the prop, as ſhewn at *fig.* 1.

Fig. 5. is a vertical ſection of the ſame through the line *a b*.

Fig. 9. is the iron key with an aperture in the end, which fits the ſquare pin, *a*, in the door, as ſhewn at *fig.* 3, and is uſed to remove the door from the front of the furnace when it is hot.

FURNACE, *Founders*, is of different forms, according to the kinds of works to be caſt. See FOUNDERY and IRON.

FURNACE, *Glaſs-Houſe*. See GLASS.

FURNACE *for Glaſs-Painters*. See PAINTING *on Glaſs*.

FURNACE, *Hatters*. See HAT.

FURNACE, *Lamp*. See LAMP.

FURNACE, *Letter Founders*. See LETTER-FOUNDERY.

FURNACE, *Melting*. See *Air*-FURNACE.

FURNACE, *Plumbers*, is of three kinds: in the firſt they melt the lead, whereof ſheets are to be caſt. This is only a ſort of large copper, or receptacle like a copper, made of fire-ſtone, and coated well round with clay, having a little iron pan at the bottom. In the ſecond, they melt the lead to be caſt in moulds for pipes, &c. which are not to be ſoldered. The third is the tinning furnace, which is a ſquare frame of wood, or ſometimes a maſs of ſtone-work, with brick hearth, whereon is made a charcoal fire, which ſerves them for the applying of thin tin leaves on the works. See PLUMBERY.

FURNACES *for baking Porcelain and Pottery*. See KILN and PORCELAIN.

FURNACES, *Portable*. See above, Knight's, Black's, Lewis's, Muſhet's, Aikin's, &c.

FURNACE *uſed for baking Tobacco-pipes*. We may, perhaps, be criticiſed for introducing into our plates the implements of ſo trifling a manufacture, but we ſhall excuſe ourſelves, on account of the ingenious ſtructure of the furnace, and the application which may be made of it to other and more important purpoſes. This furnace is to be admired for equality of the heat in every part of the crucible, or pot, in which the pipes, or other articles to be heated, are placed, at the ſame time that the flame is not permitted to enter, ſo as to ſoil the articles it contains. This crucible is marked A A, *Plate* III. *figs.* 4 and 5: it is of a cylindrical figure, terminated at the top by a hemiſphere; it is placed over the fire-place, B, and encloſed within a furnace, D D, of brick-work, lined with fire-brick E E: between this lining and the crucible is a ſpace of about four inches, all round in which the flame from the fire-place circulates, without interruption, except what ariſes from the numerous ſupports which are neceſſary to ſuſtain the crucible in its proper poſition; but as theſe are always placed edge-ways to the flame, and are very thin, they cauſe but little obſtruction to its action: the ſupports are 12 ribs, between the crucible and the lining, which form the ſame number of flues, as ſhewn by the dotted lines *x*, *fig.* 5, (the dotted circle A being the crucible): the ribs are perforated with occaſional apertures, (ſee the ſection, *fig.* 4.) to connect one flue with the adjoining; but the principal bearing of the crucible is taken from five piers, *b b c*, formed of bricks, projecting one over the other: one of theſe piers, *c*, is placed at the back of the fire-place, and the other four at the ſides *b*, *b*, and projecting at the top, nearly into the centre of the crucible, ſo as to ſupport and ſtrengthen the bottom of it, which reſts upon theſe piers, the ſpaces between which form the mouths, or commencement of the flues ſurrounding the crucible: at the top of the crucible all the flues unite in the dome, L, of the fire-brick lining, and this has a circular opening through it, leading into the chimney N.

The lining, F E E, of the chimney is open on one ſide, (ſee the plan,) to form the door, at which the pipes are taken in and out of the furnace; the opening is permanently cloſed as high as *k*, *fig.* 4, by an iron plate plaſtered with fire-clay; above this it is left open, and only cloſed when the furnace is burning by temporary brick-work: when this is removed, the furnace can be filled or emptied through the opening; and, for this purpoſe, the crucible has a ſimilar opening in its ſide: when the furnace is burning, this aperture is cloſed, by an ingenious contrivance: the workman firſt ſpreads a layer of clay round the edge of the opening; he then ſticks the ſtems of broken pipes acroſs, from one ſide to the other, and plaſters the interſtices with clay in a manner exactly ſimilar to the lath and plaſter uſed in building. The whole of the crucible is made in this manner; the bottom is compoſed of a great number of fragments of pipes, radiating to

the

the centre; theſe are coated with a layer of clay at the circumference; a number of the bowls of broken pipes are inſerted into the clay: in theſe, other fragments are placed upright, to form the ſides of the crucible. The ribs round the outſide, which form the flues, are conſtructed in the ſame manner, as is alſo the dome, L, of the fire-brick lining; by this means the crucible can be made very ſtrong, but at the ſame time ſo thin, as to require but little clay to conſtruct it, and is leſs liable to ſplit by the heat, than a veſſel formed of thicker materials. This method might, we think, be advantageouſly applied in other caſes, where a very thin veſſel or lining is required for a furnace. The pipes which are to be baked are arranged within the crucible, as ſhewn in the ſection, the bowls reſting againſt the circumference, and the other ends ſupported upon circular pieces of clay, *r*, which are ſet up in the centre for that purpoſe; ſix ſmall ribs are made to project inwards, all round the crucible, at the proper heights, to ſupport the different ranges of pipes, without having ſo many reſting upon each other, as to endanger their being cruſhed by the weight. By this mode of arrangement, the furnace is made to contain 50 groſs, or 7200 pipes: theſe require to be burned from ſeven to nine hours; and the heat is at firſt brought on gently, and afterwards increaſed to the full heat required for baking this ſpecies of pottery: the fire is regulated by a ſimple kind of damper applied over the aperture in the dome, L, of the fire-brick lining. This is a mixture of horſe-dung, ſand, and pipe-clay, well worked together, and ſpread in thin layers upon coarſe brown paper: a ſheet of this being laid over the hole in the dome, ſo as to cover more or leſs of it, will give the means of increaſing or diminiſhing the draught, and, conſequently, the heat of the furnace.

We ſhall conclude this article with ſome uſeful hints relative to the different kinds of fuel, the management of furnaces, and the quality and form of crucibles.

The fuel employed is of three kinds; namely, pit-coal, coak, and charcoal; the firſt of which is ſeldom employed but for reverberatory furnaces, where ſubſtances are to be heated by flame, or heated air. The nature of coaks varies according to the manner of preparing them, and the nature of the coal. For ſome purpoſes, ſuch as melting ſteel, or in other ſituations, where long continued and intenſe heat is required, the coaks are made ſo hard as to exhibit a bright, white, cryſtalline fracture. In other caſes, where great heat is not required, and where expedition is more an object, the ſoft coaks are preferable. When a clear fire, free from ſmoke, and the ſuffocating vapour of ſulphurous acid, from pit-coal coak, is required, charcoal is found exceedingly convenient. Charcoal is alſo ſometimes mixed with coak, for the purpoſe of making the coak kindle more ſpeedily.

When coak, or pit-coal, is employed, the grate is liable to be choaked, from the fuſion of the earthy matter with which it moſtly abounds. An iron rod, with a hook at one end, is uſed for removing this ſubſtance from the grate, which otherwiſe would prevent the paſſage of the air. After an air-furnace has been uſed for ſeveral hours, when the fire is let out, the bars ought to be taken out for the purpoſe of removing all the ſlaggy matter.

Nothing, perhaps, is of more importance, in the dry operations of chemiſtry, than good crucibles. Formerly we had no good crucibles but what came from Holland, and thoſe termed Heſſian crucibles. The moſt eſſential point in making good crucibles, is to get clay as free as poſſible from metallic oxyds, particularly iron. A crucible ſhould be capable of bearing a heat that will thoroughly fuſe the ſubſtance put into it, without becoming itſelf ſo ſoft, as not to bear lifting out of the fire. And it ſhould alſo be capable of bearing ſudden extremes of heat and cold, without cracking. The firſt of theſe objects is attained, by introducing as much pure clay into its compoſition as poſſible. Crucibles, made ſolely of clay, however, are very liable to crack with extremes of heat and cold. This latter evil has been avoided, by mixing the coarſe powder of burnt clay with the pure clay; and ſometimes for the burned clay pure white ſand has been uſed. The crucibles uſed for melting ſteel, which requires greater heat than is generally uſed, are made with Stourbridge clay, and the powder of other hard coaks, which are uſed as fuel. Theſe pots will ſometimes bear four heats, or meltings, without cracking or loſing their form.

The inſide of a crucible is in figure nearly a paraboloid, and the outſide a truncated cone; ſo that the ſides are gradually thicker towards the bottom. The ſtands and covers of crucibles ought to be made of the ſame materials as the crucibles: the ſtand ſhould be cylindrical, and of the diameter of the bottom of the crucible.

Previouſly to a crucible being put into the fire, it ſhould be gradually heated to at leaſt a low red heat; and a good crucible, which has been heated till it begins to vitrify, can ſeldom be truſted a ſecond time in the fire.

A crucible ſhould never be introduced, or taken out of the fire by tongs, holding it by one ſide only, but by ſuch as will embrace it cloſely on the outſide, by having the mouth of the tongs of the curvature of the crucible. When a crucible is very hot in the furnace, the fire ſhould not be ſuffered to get very low, ſince the introduction of a great quantity of cold fuel will be liable to break the crucible. Crucibles are much more liable to crack when they have been baked very hard. If they are merely hard enough to bear putting into the fire, and to bear the weight of the materials, it is ſufficient.

FURNACE, *Reverberatory*. See above, Dr. Black's, Mr. Muſhet's, and the article IRON.

FURNACE. See TORNAGE.

FURNEAUX, PHILIP, in *Biography*, was born at Totneſs, in Devonſhire, in the year 1726. He received his claſſical education at the free-ſchool of his native town, and was a contemporary with the celebrated Dr. Kennicott. An intimacy between theſe learned men was contracted in youth; it increaſed in advancing life, and continued till death ſeparated the bonds of friendſhip. The object of their purſuits was ſimilar, though they took different methods to attain it. Dr. Kennicott was a member of the eſtabliſhed church, but Mr. Furneaux ſought for learning, and aimed to be uſeful among the Diſſenters. He ſtudied under the patronage of Mr. Coward's funds, and having diligently purſued that courſe of learning which is preparatory to the exerciſe of the miniſtry, he ſettled with a congregation at St. Thomas' Southwark, and ſoon afterwards was choſen one of the Sunday evening lecturers at Salters' hall, in London. He became a very diſtinguiſhed preacher, on account of the ſolemnity and fervour of his manner, and the energy of his pulpit diſcourſes. In 1753 he removed to Clapham, and ſucceeded Mr. Moſes Lowman, the well-known writer on the book of Revelation,

as paſtor of the diſſenting congregation in that village. Here he continued his miniſterial duties for more than 23 years, and under his labours that ſociety became one of the moſt opulent and reſpectable in the neighbourhood of the metropolis. During this period he received the diploma of doctor of divinity, and was elected one of the truſtees to the fund, to which he was in a great meaſure indebted for his education. In the year 1777 he was attacked by a malady, which terminated in mental derangement, from which he never completely recovered till his death, which happened in the year 1783, when he had attained to his fifty-eighth year. As a writer of great force and energy, Dr. Furneaux is known by a few ſingle ſermons, but to general readers, more particularly by his "Letters to the honourable Mr. Juſtice Blackſtone, concerning his Expoſition of the Act of Toleration, and ſome poſitions relative to religious liberty, in his celebrated Commentaries on the Laws of England." The judge never condeſcended to notice this able attack upon his work, but he did more; he felt he had taken his ſtand on ground that was not tenable, and in his ſubſequent editions omitted ſome obnoxious paſſages and altered others, which had brought upon him the animadverſions of Dr. Furneaux. To the ſecond edition of this work, publiſhed in 1771, an appendix was ſubjoined, containing "Authentic copies of the argument of the late honourable Mr. Juſtice Foſter, in the court of the Judges Delegates, and of the ſpeech of the Right honourable lord Mansfield, in the Houſe of Lords, in the cauſe between the city of London and the Diſſenters, in the year 1767;" this latter he wrote entirely from memory, but with ſuch correctneſs, that it received the full approbation of the learned lord, with whoſe notes, taken on the occaſion, it fully correſponded. So highly did his lordſhip regard the doctor, that when under the moſt grievous calamity, to which we have referred, he contributed liberally to his ſupport. Dr. Furneaux was author likewiſe of "An Eſſay on Toleration," in which he had a particular view to an application which had then been lately made by the diſſenting miniſters to parliament. Gen. Biog.

FURNEAUX *Iſland*, in *Geography*, an iſland in the Pacific ocean, lying in S. lat. 17° 5′. W. long. 143° 16′, diſcovered by Bougainville, and afterwards by captain Cook, ſo named in honour of captain Furneaux, who commanded the Adventurer in his ſecond voyage. This iſland, together with Reſolution iſland, S. lat. 17° 24′. W. long. 141° 39′; Doubtful iſland, S. lat. 17° 20′. W. long. 141° 38′; and Adventure iſland, S. lat. 17 4′. W. long. 144° 30′, and ſeveral others, conſtitute a cluſter of low, and half-drowned iſles, denominated by the French navigator the "Dangerous Archipelago." Furneaux iſland is rather a coral-ſhoal than an iſland, of about 20 leagues in circuit. The ſmall part of it, which is land, conſiſts of little iſlets ranged along the north ſide, and connected by ſand-banks and breakers. Theſe iſlets are clothed with wood, among which the cocoa-nut trees are diſtinguiſhable. Captain Cook ranged the ſouth ſide of this ſhoal at the diſtance of one or two miles from the coral-bank, againſt which the ſea broke in a tremendous ſurf. In the middle is a large lake or inland ſea, in which was a canoe under ſail.

FURNES, or VUERNE, a town of France, and chief place of a diſtrict in the department of the Lys, ſeated on the canal that leads from Bruges to Dunkirk, about three miles from the ſea. The town-houſe is a good building, adorned with figures of kings and princes; it has a handſome tower, with muſical chimes; 15 miles S. W. of Oſtend. The place contains 3,220, and the canton 13,088 inhabitants, on a territory of 192½ kiliometres, in 19 communes. The whole extent of the diſtrict comprehends 715 cantons, 91 communes, and 49,808 inhabitants. N. lat. 51° 4′. E. long. 2° 27′.

FURNITURE, in *Dialling*, certain additional points and lines drawn on a dial, by way of ornament.

Such are the ſigns of the zodiac, length of days, parallels of declination, azimuths, meridians of the principal cities, Babylonic and Italian hours, points of the compaſs, &c. See DIAL.

For drawing furniture on dials, the *analemma*, or trigon of ſigns, is an inſtrument of principal uſe.

FURO, in *Zoology*, a name given by ſome authors to the *Ferret*, a ſpecies of the MUSTELA, which ſee.

FUROR UTERINUS, in *Medicine*, a term employed by Sennertus, and others, to denote a ſpecies of madneſs in females, which is principally characterized by an ungovernable deſire for the ſexual intercourſe. It is called by the noſologiſts *Nymphomania*, which ſee.

FURR, in *Commerce*. See FUR.

FURRETIERRE, ANTHONY, in *Biography*, was born at Paris in 1620. He was intended for the profeſſion of the law, and obtained an office in that department, but at length entered the eccleſiaſtical ſtate, and roſe to preferment in the church. He was diſtinguiſhed by ſome compoſitions in verſe and proſe, and became a member of the French academy, the meetings of which he attended with great aſſiduity; but being embroiled in diſputes reſpecting a dictionary which he propoſed to publiſh, and which was ſuppoſed to have originated from one then compiling under the auſpices of the academy, he was expelled, and continued, till his death, in a ſtate of expulſion. The academy was not content with carrying on their reſentment while the object of it was alive, but decreed that the uſual funeral ſervice performed on the deceaſe of a member ſhould not be performed for Furretierre. This was in the year 1688: His "Dictionnaire Univerſel" did not appear till two years after his death. An improved edition was publiſhed in 1701, in three volumes folio, and again in four volumes at Amſterdam in 1725. This work has ſerved as the baſis of the "Dictionnaire de Trevoux," publiſhed in 1771, in eight volumes. Furretierre was author of other works, as "Five Satires, in Verſe;" "The Goſpel Parables, in Verſe;" and "Le Roman Bourgeois." Moreri.

FURRS, *Timber of*. See TIMBER.

FURR, in *Heraldry*, a repreſentation of the ſkins of certain wild beaſts, ſeen both in the doublings of the mantles of coat-armour, and in the armour itſelf.

The heralds uſe two metals, five colours, and two furrs, or hairy ſkins; *viz.* ermine and vair.

The origin of theſe furrs Mackenzy aſcribes to the ſhield's being anciently covered with ſkins; which ſkins, or coverings, were afterwards repreſented in the ſhields; a more probable derivation, in our opinion, than to ſay they were placed on ſhields, becauſe they had been worn in mantles and garments.

Furrs either conſiſt of one colour, which is white; but cannot be uſed in arms ſingly, or more than one; and theſe either two, or more than two.

Furrs of two colours are either ermine, being white with black ſpots; ermines, black with white ſpots; ermines, whoſe ground is yellow, and the powdering black; or pean, which is black powdered with yellow. When the ground is white, powdered with black ſpots, each ſpot having one red hair in the middle, it is called erminites.

Furrs of more than two colours are called *vair*, and *vairy*; which ſee.

FURRIER,

FURRIER, a perſon who trades, or works, in furrs, or lines robes, &c. therewith.

FURRIER'S *Clippings*, in *Agriculture*, the refuſe clippings produced in large manufactories by furriers; and which are capable of being employed as manure with great advantage. They are much employed in Hertfordſhire and ſome other counties contiguous to the metropolis; where they are uſually purchaſed at from about twelve to thirteen ſhillings the quarter, which conſiſts of a ten-buſhel ſack crammed quite full, and moſtly weighing about two hundred and a half. They are conveyed to the lands at the expence of about three-pence the quarter. And they are applied by ſowing them over the ground, by the hand, from a ſeed-ſcuttle, at the further charge of about three-pence the quarter, where wheat or barley is deſigned to be ſown, being immediately afterwards turned in by the plough, and then the ſeed is ſown and harrowed in. After this has been done all ſuch pieces of the clippings as are left above the ſurface are picked, dibbled, or ſhoved into the mould by the point of a ſtick made for the purpoſe, in order to prevent their being carried away or devoured by dogs, crows, &c. which are very fond of eating them. The quantity generally made uſe of to the ſtatute acre is about three-quarters. They are found to anſwer extremely well on light, dry, chalky, or gravelly ſoils, where they are ſuppoſed to hold the moiſture in a manner ſo as to prove of great aſſiſtance to the crops in ſuch ſeaſons as are hot and dry. In the wetter ſorts of land they are not believed to afford much benefit. See MANURE.

FURRING *of a Ship*, is laying on double planks on her ſides. This is done after the ſhip is built, and is by the ſailors called *plank upon plank*. But there is another way of furring, which is more properly ſo called; and that is, when a ſhip's planks are ripped, and new timbers are put on the former timbers, and on them other planks; which is done ſometimes to make the ſhip bear the ſails the better.

FURRINGS, or *Furrs*, in *Architecture*, are uſed for the making good of the rafter-feet in the cornice.

When rafters are cut with a knee, theſe furrings are pieces which go ſtraight along with the rafter, from the top of the knee to the cornice.

When rafters are rotten or ſunk hollow in the middle, there are pieces cut thickeſt in the middle, and tapering towards each end, which are nailed upon them to make them ſtraight. Such pieces are called furrs; and the putting them on is called furring the rafters.

FURRIPOUR, in *Geography*, a town of Hindooſtan, in Rohilcund; 12 miles S. of Barcilly.

FURROW, among *Gardeners*, denotes a ridge or ſwelling on the ſide of a tree, ſtalk, or fruit.

FURROW, in *Agriculture*, the trench or opening made by the plough in breaking up, turning, or ſtirring land. The furrows ſhould in general be leſs perfectly turned when for the ſeed, than in caſes of breaking or ſtirring the ground.

FURROW-*plough*, ſuch as is employed in forming water furrows. See FURROWING *Plough*.

FURROW, *Two*, or *Double Plough*, a name applied to ſuch ploughs as are conſtructed in a double manner, or ſo as to produce two furrows at the ſame time. See PLOUGH.

FURROW-*roller*, a particular tool of the roller kind, contrived ſo as to operate in the furrows of the ridges.

FURROW-*ſlice*, the narrow ſlice or ſlip of earth raiſed and turned over by the plough, in breaking up or ſtirring land.

The Scotch writers on huſbandry frequently denominate it *fur-ſlice*.

FURROW, *Water*, a deep open ſort of trench or furrow, made by a plough, contrived for the purpoſe or otherwiſe, in lands under tillage, in order to draw off and drain them of the water that may ſtagnate or prove injurious to the growth of the crops. Theſe furrows ſhould conſtantly be drawn in ſuch directions as are the moſt proper for readily diſcharging the water, even ſlanting acroſs the ridges where the nature of the ſituation requires it; and be kept perfectly open and free by means of the ſpade during the winter months, eſpecially where the land is inclined to be wet, and the crops are of the wheat kind. The forming of theſe furrow-drains ſhould be executed immediately after the ſowing of the land has been finiſhed. They are particularly neceſſary on all the more ſtiff and retentive ſorts of land, as without them the crops ſeldom ſucceed well in ſuch caſes.

FURROWING PLOUGH, a ſort of plough conſtructed for the purpoſe of forming water-furrows in lands of the more heavy moiſt kinds.

This ſort of work is much more readily, as well as much more effectually performed, by this ſort of plough than thoſe of the common kind. See PLOUGH.

FURRUCKABAD, in *Geography*, a town of Hindooſtan, in the circar of Rohilcund, on the weſt ſide of the Ganges, and capital of a diſtrict belonging to a prince of the Patan Rohilla tribe; about 30 miles in length along the bank of the Ganges; 76 miles N.W. of Lucknow. This ſmall independent territory has been added to the Britiſh dominions. N. lat. 27° 23'. E. long. 79° 52'.—Alſo, a town of Hindooſtan, in the country of Bengal, near the Ganges; 42 miles N.N.W. of Moorſhedabad.

FURRY'S TOWN, a town of the iſland of Jamaica, in the county of St. James; 20 miles N.E. of Savannah-la-Mer.

FURSEY, a ſmall iſland of England, at the entrance into Pool harbour.

FURSHOUT. See FARSCHOUT.

FURSTEMBERG, FERDINAND DE, in *Biography*, an eminent prelate, was a deſcendant from the free barons of that name in Weſtphalia, and was born at Bilſtein in 1626. He ſtudied at Cologne, where he contracted an intimate friendſhip with Chigi, who was then nuncio, and afterwards a cardinal and pope. During the cardinalateſhip of Chigi, he invited Furſtemberg to reſide with him, whom he raiſed to the biſhopric of Paderborn in 1661, when he himſelf was ſeated in the papal chair, under the title of Alexander VII. The high reputation of the biſhop attracted the notice of Van Galen, who appointed him his coadjutor, and whom he ſucceeded in 1678, when he was declared by the pope apoſtolical vicar of all the north of Europe. He was a zealous catholic, and anxious for the converſion of thoſe who were not already within the pale of the church; but at the ſame time he did not neglect the cultivation of the belles lettres, either by his own efforts or thoſe of many learned men whom he patronized. He died in 1683. As an author he collected a number of MSS. and monuments of antiquity, and gave to the world a valuable work relative to thoſe ſubjects, entitled "Monumenta Paderbornenſia." He alſo printed at Rome a collection of Latin poems, entitled "Septem Virorum illuſtrium Poemata." In this work there were many poems of his own, written with much purity. A magnificent edition of theſe poems was publiſhed in the ſame year in which he died, at the Louvre, at the expence of the king of France. Moreri.

FURSTENAU, JOHN-HERMAN, was born at Herforden, in Weſtphalia, in the month of May, 1688. Having paſſed through his early ſtudies in his native town, he commenced his courſes of medicine in Saxony at the age of eighteen, and attended with diligence the ſchools of Wittemberg, Jena, and Halle, and became a licentiate in medicine in the laſt mentioned univerſity. About 1709 he returned to Herforden, and immediately obtained a conſiderable ſhare of practice; but having conceived the deſign of viſiting the Low Countries, he commenced his journey in 1711, in order to hear thoſe great maſters of his art, who at that time flouriſhed ſo numerouſly in the cities of Amſterdam, Leyden, Utrecht, the Hague, Delft, and Dordrecht. Having profited much by their inſtructions, whether in the chair, in hoſpitals, or in private communication, he returned to his native place at the end of a year, and recommended the practice of his profeſſion with the ſame ardour as when he quitted Halle, but with more knowledge and greater reſources. Nevertheleſs he again interrupted his practice by another journey in 1716. He married in 1717, with the intention of ſettling at Herforden; but Charles I. landgrave of Heſſe, cauſed him to remove thence, in order to take an appointment in the univerſity of Rintlen, where he became a profeſſor in 1720. He died at Rintlen on the 7th of April, 1756, at the age of 68 years. He left ſeveral works: the firſt of theſe was frequently re-printed, and bears the title of "Deſiderata Medica." It includes alſo "Deſiderata Anatomico-Phyſiologica; Deſiderata circa morbos et eorum ſigna; Quæ deſiderantur in Praxi Medica; Deſiderata Chirurgica." 2. "De Fatis Medicorum, Oratio Inauguralis," 1720. 3. "De morbis Juriſconſultorum Epiſtola," 1721. 4. "De Dyſenteria alba in puerperâ Diſſertatio," 1723. 5. "Programmata nonnulla, tempore Magiſtratûs Academici impreſſa," 1724 and 1725.

FURSTENAU, in *Geography*, a town of Germany, in the biſhopric of Oſnabruck; 15 miles N.N.W. of Oſnabruck.—Alſo, a town of Saxony, in the margraviate of Meiſſen; 3 miles S. of Lauenſtein.—Alſo, a town of Pruſſia, in Pomerania, 8 miles N. of Marienburg.—Alſo, a town of Sileſia, in the principality of Breſlau; 15 miles S.W. of Breſlau.—Alſo, a town of Germany, in the county of Erbach, on the Mumling; 4 miles N. of Erbach.

FURSTENBERG, a town of Germany, in the county of Waldeck; 10 miles N. of Waldeck.—Alſo, a town of Germany, in the principality of Furſtenberg, with an ancient caſtle, which gives name to an ancient family, princes of the empire; 14 miles N.N.W. of Schaffhauſen. N. lat. 47° 57'. E. long. 8° 27'.—Alſo, a principality of Germany, in the circle of Swabia, founded in the 13th century, and divided into ſeveral branches, all of which are extinct except that of Stuhlingen.—Alſo, a town of Germany, in the biſhopric of Paderborn; 2 miles N.E. of Wenenburg.—Alſo, a town of Luſatia, on the Oder; 13 miles S. of Francfort on the Oder. N. lat. 52° 7'. E. long. 14° 48.—Alſo, a town of Germany, in the duchy of Mecklenburgh, on the Havel; 10 miles S.E. of Strelitz. N. lat. 53° 10'. E. long. 13° 14'.

FURSTENECK, a town and caſtle of Germany, in the biſhopric of Fulda; 13 miles N. of Fulda.

FURSTENFELD, a town of the duchy of Stiria, on the confines of Hungary, near the conflux of the rivers Feiſtritz and Laufnitz; 30 miles E. of Gratz. N. lat. 47° 3'. E. long. 15 59'.—Alſo, a town of Germany, in the New Mark of Brandenburg; 10 miles N. of Cuſtrin. N. lat. 52° 48'. E. long. 14° 42'.

FURSTENWALDE, a town of Germany, in the Middle Mark of Brandenburg, on the Spree; 26 miles E. of Berlin. N. lat. 52° 22'. E. long. 14° 8'.—Alſo, a town of Saxony, in the margraviate of Meiſſen; 2 miles S. of Lauenſtein.

FURSTENWERDER, a town of Germany, in the circle of Upper Saxony, between the Damſee and Wahrenſee, in the Ucker Mark of Brandenburg; 10 miles W.N.W. of Prenzlow. N. lat. 53° 23'. E. long. 13° 36'.

FURTH, a town of Lower Bavaria, on the Champl; 56 miles N.N W. of Paſſau. N. lat. 49° 17'. E. long. 12° 42'.—Alſo, a town of Germany, in the circle of the Lower Rhine; 6 miles S.E. of Heppenheim.—Alſo, a town of Germany, in the principality of Anſpach, on the Rednitz; large and well-peopled, with a number of artiſans. In this town the Jews have a ſynagogue and a printing-office; 4 miles W. Nuremberg.

FURUM, a ſmall iſland in the Baltic, near the E. coaſt of Sweden. N. lat. 57° 17'. E. long. 16° 32'.

FURUNCULUS, (from *furo*, to rage, on account of the violent inflammatory ſymptoms which precede ſuppuration,) a term, in *Surgery*, ſignifying what is more commonly called a boil, which is well known to be a circumſcribed, very prominent, hard, deep red, exceedingly ſore, inflammatory, little ſwelling, ſcarcely ever becoming larger than a pigeon's egg, and, in general, being conſiderably ſmaller.

The tumour, as Mr. Pearſon has deſcribed, generally appears under the figure of a cone, the baſe of which is a good deal below the ſurface, while the apex is ſeldom much elevated above the level of the ſkin. Upon the moſt prominent part of the boil there is commonly a whitiſh or livid puſtule, which is exquiſitely ſenſible, and immediately under which the abſceſs is ſituated. For the reader ſhould underſtand that it is the diſpoſition of a boil to enter into an imperfect kind of ſuppuration, which alſo takes place with remarkable ſlowneſs. The matter contained in the ſwelling is ſmall in quantity, mixed with red globules, and ſurrounded by a ſloughy ſubſtance, which forms a ſort of cyſt.

In ordinary caſes, only one boil occurs on the ſame ſubject, but ſometimes many ſuch tumours are met with on the ſame patient. This is ſaid to happen more particularly on children, and after the termination of ſome acute diſeaſe.

A boil is ſeldom ſo afflicting a complaint as to require the attendance of a ſurgeon, unleſs when the ſwelling is above the uſual ſize, or there are ſeveral affecting the ſame patient, and producing febrile ſymptoms.

We may obſerve that the furunculus is a complaint which is much more common in children and young perſons than in people more advanced in life. One may infer from this circumſtance, and from ſeveral of theſe tumours often occuring on the ſame patient, that the cauſes are of a conſtitutional deſcription, although their exact nature ſeems involved in obſcurity.

The chief indications in the treatment are, in general, to promote ſuppuration, to make a free and early opening with a lancet, and to preſs out the matter and ſloughs. The poultice may then be continued two or three days longer, at the end of which time any ſimple dreſſing will ſerve to complete the cure.

In the majority of caſes it would only retard the termination of the complaint to attempt to bring about a reſolution of the inflammation, ſo great is the tendency to that kind of ſuppuration which we have above deſcribed. Some authors allow, however, that a few inſtances do occur in which ſuch

an

an endeavour may very properly be made, by applying a mixture of honey and vitriolic acid, or elſe ſpirit of wine or camphorated oil.

For the moſt part ſuppuration is to be promoted, and then the beſt application is a ſmall linſeed poultice.

If the ſurgeon were to wait events, a ſmall opening, inadequate to the diſcharge of the matter and ſloughs, would be ſpontaneouſly formed after a conſiderable time. Hence, the advantage of taking an early opportunity to make a free opening with a lancet, after doing which, as much of the contents of the ſwelling ſhould be preſſed out as can be done without producing too much pain. It is always proper, in this, as in every other inflammatory caſe, to adminiſter gentle aperient medicines, and alſo febrifuge ones, when any fever prevails.

When any induration remains after the ſore is healed, the part ſhould be rubbed with a little mercurial ointment.

Some ſurgical writers deſcribe a chronic ſpecies of boil, which, they ſay, is frequently met with in ſubjects who have ſeverely ſuffered from the ſmall-pox, meaſles, lues venerea, ſcrofula, or uſe of mercury. (See Munnick's Praxis Chirurgica, cap. 3. p. 19.) Mr. Pearſon ſtates, amongſt other circumſtances, that this kind of furunculus is commonly ſituated on the extremities; that it is not attended with much pain, nor any material diſcolouration of the ſkin, until ſuppuration is a good deal advanced; that maturation is ſeldom completed in leſs than three or four weeks; that the contents of the tumour are a thin ſanies; and that, when the ſwelling is large, and ſuppuration has been very ſlow, a good deal of cellular ſubſtance will be diſcharged in the form of ſloughs, leaving a very deep cavity. (See Principles of Surgery, p. 72—73).

There can be no doubt, that, in this laſt caſe, the large quantity of gangrenous miſchief might be prevented by making a free and early opening in the tumour with a lancet. This maxim cannot be too ſtrongly inſiſted upon in every inſtance of anthrax and troubleſome boils.

We agree with Mr. Pearſon, that bark and opium may ſometimes prove uſeful to patients labouring under very painful ſloughy boils; but we regard his precept to apply the hydrargyrus nitratus ruber to the gangrenous cavity, as only deſerving of univerſal condemnation. The pernicious cuſtom of cramming any abſceſſes with red precipitate met with the juſt reprobation of that diſtinguiſhed practitioner, Mr. Pott, who expoſed the abſurdity of the practice in his treatiſe on the fiſtula in ano, and we confidently believe, that, in the preſent improved ſtate of ſurgical knowledge, Mr. Pearſon may offer the above bad advice without the leaſt danger of its being followed. If he could turn one apothecary's apprentice into an advocate for ſuch employment of the red precipitate, we confeſs that we ſhould be ſomewhat ſurpriſed; for, although an author may ſet up for a dogmatiſt, and deliver an erroneous aſſertion with all the formality of the hundred and twenty-fifth aphoriſm, the counſel, if very abſurd, will only be reſpected till the deluded ſtudent happens to open another ſurgical book.

FURUNCULUS, in *Zoology*, the name given by many authors to the ferret, called alſo the *furo* and *ictis*. See MUSTELA *furo*.

FURUO, in *Geography*, a ſmall iſland in the N. part of the gulf of Bothnia. N. lat. 65° 40'. E. long. 22° 24'.

FURUSUND, an iſland in the Baltic, belonging to Sweden. N. lat. 59° 46'. E. long. 18 45'.

FURZE, in *Botany*. See ULEX.

FURZE, in *Agriculture*, a ſort of low ſhrubby plant, of a very hardy nature, and which is armed with prickles. By ſome botanical writers it is known under the name of *geniſta ſpinoſa*, and by others under that of *ulex europæus*, and provincially it is often termed *whin* or *gorſe*. It will grow well on moſt kinds of poor dry ſoils, and it propagates ſo rapidly by the ſeeds, that, where once eſtabliſhed in a ſpot of ground, it ſoon overſpreads the whole ſpace; for, as the ſeeds ripen, their pods are opened by the warmth of the ſun, and they are thrown out to a conſiderable diſtance all around, where they vegetate, and ſoon fill the ground with young plants.

It is probable that this plant may, in ſome ſituations, and under particular circumſtances, be cultivated to advantage for the feeding of horſes and ſtore cattle, on light, poor, ſandy, dry ſoils, which cannot be employed in the growth of grain, or crops of green vegetables. This method of making uſe of furze has prevailed for a conſiderable length of time, both on the continent and in ſome parts of this kingdom, as in the more northern parts of Scotland.

Where furze is raiſed on purpoſe for the food of cattle, and eſpecially on ſoils like the above-mentioned, their ſeeds ſhould be ſown in February, March, or April, and the ground be prepared as for barley. Six pounds of ſeed are ſufficient for an acre of land; being but lightly covered over. The young plants muſt be preſerved from cattle during the firſt year, and they will be fit to mow or cut in the next. The following methods of cultivating this plant, with the view of converting it to the feeding of animals, have been found by Dr. Anderſon to be the moſt ſucceſsful on the better kinds of land. A field of a good, dry, loamy land, being well prepared, he ſowed, along with a crop of barley, the ſeeds of the whin in the ſame way as clover is uſually ſown, allowing at the rate of from fifteen to thirty pounds of ſeed to the acre. The ſeeds, if harrowed in, and rolled with the barley, quickly ſpring up and advance under the ſhelter of the barley, during the ſummer, and keep alive during the winter. Next ſeaſon, if the field has not a great tendency to run to graſs, ſo as to choke them, they advance rapidly after Midſummer, ſo as to produce a pretty full crop before winter. This you may begin to cut with the ſcythe immediately after your clover fails, and continue to cut it as it is wanted during the whole of the winter; but it is ſuppoſed, he ſays, that after the month of February the taſte of this plant alters, as it is in general believed that after that time horſes and cattle are no longer fond of it. It is however obſerved, that never having had a ſufficiency of whins to ſerve longer than till towards the middle of February, or beginning of March, he cannot aſſert this fact from his own experience. He has frequently ſeen horſes beating the whins with their hoofs ſo as to bruiſe the prickles, and then eat them, even in the months of April and May; and he ſays, that ſheep which have been uſed to this food certainly pick off the bloſſoms and the young pods at that ſeaſon, and probably the prickles alſo; ſo that it is poſſible the opinion may only be a vulgar error without any foundation in truth.

This is, the writer thinks, the beſt way of rearing whins as a crop for a winter food for cattle or horſes. But for ſheep, who take to this food very kindly when they have once been accuſtomed to it, leſs nicety is required; for, if the ſeeds be ſimply ſown broad-caſt very thin (about a pound of ſeed per acre), upon the pooreſt ſoils, after they come up the ſheep of themſelves will crop the plants, and ſoon bring them into round cloſe buſhes, as this animal nibbles off the prickles one by one very quickly, ſo as not to be hurt by them. Sheep, however, who have not been uſed to this mode of browſing, do not know how to proceed, and often will not taſte them, but a few that have been

been uſed to the food will, the writer obſerves, ſoon teach all the reſt how to uſe it.

And another very economical way of rearing whins, but which he has ſeen practiſed, rather than experienced himſelf, is this. Let a farm be incloſed by means of a ditch all round, with a bank thrown up on one ſide; and if ſtones can be had, let the face of that bank be lined with the ſtones, from bottom to near the top; this lining to ſlope backwards with an angle of about ſixty or ſeventy degrees from the horizon. Any kind of ſtones, even round ones gathered from the land, will anſwer the purpoſe very well: upon the top of the bank ſow whin ſeeds pretty thick, and throw a few of them along the face of the bank. Young plants will quickly appear. Let them grow for two years, and then cut them down by means of a hedge-bill, ſtripping down by the face of the bank. This mode of cutting is very eaſy; and as the ſeeds ſoon inſinuate themſelves among the crannies of the ſtones, the whole face of the bank becomes a cloſe hedge, whoſe ſhoots ſpring up with great luxuriance. If another ditch be made on the other ſide of the bank, and if this be managed in the ſame way, and the hedge cut down only once every ſecond year, (and in this way it affords very good food for beaſts,) the inſide and outſide being cut down alternately, the fence will at all times continue good, as the hedge at the top will at all times be complete. This mode of rearing whins is, he remarks, both convenient and economical. But where ſtones cannot be obtained for making the facing, the bank very ſoon moulders down, and becomes unfit for the purpoſes of a fence. This will alſo often be the caſe where ſtones are made uſe of when the ſoil is of a looſe nature.

Various circumſtances have, the writer ſays, prevented him from aſcertaining what is the weight of the crop that may be thus obtained; but he thinks he may ſafely venture to ſay that it is at leaſt equal to that of a crop of green clover; and if it be conſidered that this affords a green ſucculent food during winter, on which cattle can be fatted as well as on cut graſs in ſummer, it will, he thinks, be admitted, that it muſt be accounted even a more valuable crop than clover. After being cut, he alſo remarks that it ſprings up the following ſeaſon with greater vigour than before; and, in this ſituation, acquires a degree of health and ſucculence very different from what it is ever obſerved to poſſeſs in its natural ſtate. He has ſeen ſhoots of one ſeaſon near four feet in length. The prickles too are ſo ſoft, and the ſtones ſo tender, that very little bruiſing is neceſſary; indeed horſes, that have been accuſtomed to this food, would eat it without any bruiſing at all; but cattle, whoſe mouths ſeem to be more tender, always require it to be well bruiſed. How long crops of this ſort may continue to be annually cut over, without wearing out, he cannot ſay; but he believes a long while, in favourable circumſtances; however, one thing is neceſſary to attend to in order to guard againſt its being deſtroyed. As, during the beginning of the ſeaſon nature ſeems to be ſolely employed about the work of fructification only, and it is not till near Midſummer that the whin begins to puſh forth its wood-bearing branches, which advance with great luxuriance only during the latter part of the ſeaſon, it may happen that if care be not taken to have the graſs that ſprings upon the field before the whin begins to ſend out its ſhoots eaten cloſe down, that graſs will acquire ſuch a luxuriance before the young branches of the whin begin to advance, as to overtop them, and choke them entirely. Whoever, therefore, has a field under this particular crop muſt, he ſays, be careful to advert to this circumſtance; or, if the field be in good heart he will infallibly loſe it. The field therefore ſhould be kept as a paſture, as bare as poſſible during the beginning of the ſeaſon, and the cattle ſhould only be taken from it when the ſhoots of the whin are diſcovered to begin to advance with vigour. Under this management, he preſumes it may be kept for many years, and yield full crops: but unleſs the mowers be particularly attentive, at the beginning, to cut it as low as poſſible, it will very ſoon become impoſſible to cut the field with a ſcythe, as the ſtumps will ſoon acquire ſo much ſtrength as to break the ſcythe when it happens to touch them in any ſtrong part.

It has been remarked, in a paper in the ninth volume of the Annals of Agriculture, that by cutting a part of the ground down in this way, every third year, very large crops may be obtained. It is alſo probable, that the plants may continue longer. October is the proper time to begin mowing or cutting them. They continue to ſhoot till Chriſtmas, and are fit for uſe until March. Horſes are ſaid to eat them as readily as they do hay, after they have been chopped with a cleaver, and bruiſed or pounded by a mill, or otherwiſe, ſo as to take off their ſharp points; and it is ſaid, that an acre of ground will produce ten or fifteen tons of this fodder, and that it will go as far as an equal quantity of hay. Some mix the bruiſed furze with chopped ſtraw; an hundred of ſtraw to a ton of furze; but in whichever way employed, only the growth of the year ſhould be cut for the cattle to feed upon.

It has been further remarked, by Dr. Anderſon, that he knows few plants that deſerve the attention of the farmer more than the whin. Horſes are particularly fond of it, ſo much ſo, that ſome perſons think they may be made to perform hard work upon it, without any feeding of grain; but he thinks it tends more to fatten a horſe than to fit him for hard labour, and that therefore ſome grain ſhould be given with it where the work is ſevere. Cattle, he ſays, eat it perfectly well when thoroughly bruiſed, and grow fat upon it as upon turnips; but unleſs it be very well bruiſed for them they will not eat it freely, and the farmer will be diſappointed in his expectations. Cows that are fed upon it yield nearly as much milk as while fed upon graſs, which is free from any bad taſte; and the beſt winter-made butter he ever ſaw was obtained from the milk of a cow that was fed upon this plant. This food ſhould be made uſe of ſoon after being prepared. Two buſhels, with a proper allowance of hay, have been found to be ſufficient for a day, for three horſes, performing the ſame labour as with corn. It alſo ſeemed uſeful to horſes labouring under broken-wind and greaſe. Poor hungry gravelly ſoils, which would not have let for five ſhillings the acre, have alſo been rendered worth twenty ſhillings, by ſowing them with furze-ſeed, in places where fuel has been ſcarce; this being frequently uſed for heating ovens, burning lime and bricks, and alſo for drying malt; but it is not worth cultivating in countries where fuel of any kind is cheap, or upon ſuch lands as will produce good graſs, corn, or other crops employed as the food of animals.

It was formerly much the practice to ſow the ſeeds of the common furze, in order to form hedges round the fields; and where the ſoils were light, the plants ſoon became ſtrong enough for a fence againſt cattle: but as theſe hedges are apt to grow naked at the bottom, in a very ſhort time, and the plants too frequently fail, ſo as to leave conſiderable gaps, and are alſo liable to ſpread their ſeeds over the neighbouring fields, the cuſtom has of late been greatly in diſuſe.

Where, however, this practice is attempted, the ſpecies commonly known by the title of the French furze is the beſt for the purpoſe, as it thickens more near the ground,

and

and grows to a greater height. This ſort begins to blow about the middle of January, and continues in bloſſom all the ſummer; while the Engliſh furze does not blow until towards the end of the ſpring, and finiſhes its bloſſoming at the ſame time as the other.

It has been ſtated by Mr. Young, that Dr. Taylor, in Surrey, has a poor field of ſix acres, worth about ſeven ſhillings an acre, which is ſown with furze, and by that means converted to one of the moſt profitable on the farm: the land being cleared from couch in April 1782; mown in 1784 to thicken it; and cut for the firſt crop in 1786, and ſince that period regularly every two years, three acres per annum. The laſt year's cut of three acres produced ſeven thouſand ſeven hundred faggots, which ſold at 3*l.* 3*s.* the thouſand on the ſpot, which is 24*l.* 5*s.* 6*d.*; cutting and binding, one ſhilling and ſixpence the hundred, or 5*l.* 15*s.* 6*d.*; clear return 18*l.* 10*s.* Suppoſe tithes, rates and fences to equal 5*s.* rent 7*s.*, in all 12*s.*, or for three acres 1*l.* 16*s.*, this further charge deducted from the above leaves a net profit of 16*l.* 14*s.*; or per acre 5*l.* 11*s.* 4*d.*; and per acre per annum 2*l.* 15*s.* 8*d.*, which is, the writer ſuppoſes, a greater net profit than any man receives from wheat, upon ſuch ſorts of land. It is likewiſe further ſuggeſted, that the doctor ſuppoſes the produce rather increaſes than diminiſhes. In regard to the time of cutting, it is recommended as the beſt ſeaſon to perform it in dry weather in February, or the beginning of March, when the ſevere froſts are over, and there is no danger of the furze plants being injured by them.

It is not unfrequently neceſſary, in bringing waſte lands of the moor kinds into the ſtate of cultivation, to extirpate theſe plants, which is often difficult to perform. The beſt method is probably by very deep ploughing, ſo as to effectually eradicate them. As the ſeeds lie in the ground for ſome time without being injured, young plants will occaſionally make their appearance, but theſe in general readily give way to the ſubſequent ploughings and harrowings.

FURZE-*grounds*, thoſe portions or ſpots of ground that are deſtined for, or covered with furze. There are many extenſive tracts of land which are wholly covered with this ſort of plants. The author of the Rural Economy of Yorkſhire ſtates it as the opinion of a perſon of great experience, that old furze grounds, from which fuel has been repeatedly carried, and which are much depauperated, may in general be readily improved in this way: Firſt let the furze be grubbed up; then ſow graſs ſeeds on the grubbed ſurface, without ploughing; and let the land remain in this ſtate until it has acquired a degree of firmneſs, the ſmaller roots left in it being decayed, and the ſurface become covered. Then ſod-burn and lime it, &c. breaking it up for a courſe of arable crops; cloſing it with cultivated graſs. Should the furze begin again to grow and be troubleſome, the proceſs of paring and burning muſt be repeated, as in the former caſe. In this way the furze may ſoon be completely deſtroyed.

Such furze grounds as are intended to be cut over for cattle food, muſt be managed in the manner that has been directed in ſpeaking of furze. See FURZE.

FURZE-*mill*, in *Rural Economy*, is a mill, or machine, conſtructed for the purpoſe of cruſhing or bruiſing furze, in order to its being employed in the feeding of horſes, and other animals. Several different contrivances have been had recourſe to at different times in this view; but we believe that formed by a large ſtone, on the principle of the cyder mill, is the moſt effectual in performing the work.

A mill for this purpoſe may likewiſe be ſeen at the Board of Agriculture, which is ſaid to anſwer well in performing the buſineſs.

The method of conſtructing a mill for this purpoſe, and the manner of employing it, have been fully deſcribed and pointed out in the fifth volume of the Tranſactions of the Bath Agricultural Society. The writer remarks that it conſiſts of a large circular ſtone ſet on its edge (the weightier and bigger the better), with a wooden axis paſſing through its centre. One end of this axis is fixed upon a pivot placed in the centre of a circular area, and to the other end of it is fixed a yoke, to which the horſe that is to move it is attached. The ſtone being placed on its edge, when the horſe moves, it revolves round its axis in a circular groove, or ſtone trough, (this trough ſhould be made of hewn ſtone,) exactly in the ſame manner as a ſugar-baker's, or a tanner's mill. The whins being placed in this trough, are bruiſed by the weight of the ſtone as it paſſes over them; and being raiſed up by a three-pronged fork by the attendant, after they have been well flatted down, they riſe in a ſort of melted cake, which, being ſet in ſome meaſure upon its edge, is again ſmaſhed down by the wheel or ſtone as it revolves. In this way the operation is continued, by ſucceſſively preſenting new ſurfaces to the action of the wheel, till the whole is reduced into a ſoft pulpy maſs, that can eaſily be eaten by the animals to which it is to be preſented. During the continuance of this proceſs, it is neceſſary, the writer obſerves, to pour plenty of water upon the whins, at different times, without the help of which they can ſcarcely be reduced to a pulp ſoft enough. On this account it will be proper to make choice of a place for the machine, where plenty of water can be obtained with little trouble. It follows alſo, that, as rain can never be prejudicial to this operation, it may be placed in the open air with propriety and advantage.

And as the operation is greatly facilitated, by a judicious way of raiſing or turning the whins, during the performance of the work, which experience will enable any attentive perſon to attain, but which cannot be taught by words only; the writer would adviſe any perſon who ſhould think of erecting an apparatus of this ſort, to put one of his moſt ſagacious ſervants to conduct this operation at the beginning, as ſuch a perſon will more quickly diſcover the circumſtances that facilitate the proceſs, than one of a ſlower comprehenſion. After he has become expert at the buſineſs, he will be able to inſtruct an inferior perſon, who may then be employed for the purpoſe. But in whatever way it ſhall be conducted, the perſon who begins this manufacture muſt lay his account with performing very little work for ſome time at the firſt, in compariſon of what he will be able afterwards to execute with eaſe, and in a more perfect manner.

It is ſuggeſted, that where the whins that are to be employed for this purpoſe grow naturally in the ſoil in irregular buſhes, it is a troubleſome work to cut and gather them. To underſtand the proper mode of managing this buſineſs in all its departments, it is, the writer thinks, neceſſary to advert to ſeveral particulars in the natural economy of this ſingular plant. Inſtead of leaves, the whin is furniſhed with an innumerable quantity of prickles. Theſe ſpring out from every part of the young ſtem, and are, at the firſt, like the ſtem itſelf to which they adhere, ſucculent, ſoft, and inoffenſive; but, like the ſtems alſo, they become gradually harder as the ſeaſon advances, and ſeem, indeed, to a caſual obſerver, to form a part of that ſtem, though they are as different from it as the leaves of other trees are from the branches which produce them. Theſe prickles do not, the writer obſerves, like the leaves of moſt deciduous trees, fall

off at the approach of winter; but, like evergreens, they remain upon the branches all winter, and retain, during that time, their full ſucculence and verdure. Early in the ſpring innumerable bloſſoms ſpring out around theſe prickles, adhering to them, and not to the ſtem. The bloſſoms are ſucceeded by pods containing the ſeeds, which gradually ripen; a little after Midſummer the ſeeds harden, and the pods ſlowly become dry and wither, the prickles to which they adhere becoming dry and withered at the ſame time, and gradually looſen from the ſtalk, which ſtill continues freſh, though it has now attained a woody conſiſtence. Theſe prickles, having now performed all the functions that nature had deſigned them, fall off in part, at firſt from the ſtalk, and in part adhere to it for ſome time, till they are gradually ſhaken off by the agitation of the wind, or other cauſes. Hence it happens, that it is only the ſurface or top twigs of a whin buſh that are green, ſoft, and ſucculent; the ſtems below being dry and woody, and frequently covered with dry prickles, that are not only not uſeful as food for cattle, but rather hurtful to them, on account of the hardneſs of their conſiſtence, and ſharpneſs of their prickles. In gathering whins, therefore, for food for cattle, they are only the tender top ſhoots that are wanted; and the eaſieſt method of gathering them that our practice has yet diſcovered, is to take a forked ſtick in the left hand (the readieſt thing is the branch of a tree of a proper ſize) and a ſickle in the right hand (both hands, but more eſpecially the right, ſhould be armed with ſtrong gloves); then thruſting the ſickle among the young ſhoots, and pulling it backward, the forked ſtick, when oppoſed to them, keeps the branches ſteady enough to produce a reſiſtance ſufficient to make the ſickle cut them; and as the tops of the whins are intermixed with each other, they ſtick to the prongs of the fork, which, after it is as full as it can hold, is taken to a ſide, and cleared by preſſing the whins to the ground and pulling the fork backwards. Theſe little heaps are afterwards forked to a cart, and preſſed down by a man walking upon them, having his legs covered with large ſtrong boots made on purpoſe, and thus are carried home. Where the whins have grown upon a good ſoil, and have made very vigorous ſhoots, they may be thus reaped pretty expeditiouſly; but if the ſoil has been poor, and the ſhoots ſhort, the expence of this operation is very conſiderable; and as theſe ſhort whins are, in other reſpects, of a very inferior quality to the others as food for beaſts, it is only at times when fodder is ſcarce and dear that they can be economically applied to this uſe. But by being cultivated in the manner that has been deſcribed in ſpeaking of furze, the labour may not only be much leſſened, but the advantages of this winter food be more fully obtained.

Some, however, in performing this buſineſs, make uſe of a very ſtiff ſhort ſcythe, which is found to execute the work quickly, and in a tolerably perfect manner, when the workman becomes fully acquainted with the method of uſing it.

FUSA, in the *Italian Muſic*, the name of one of the muſical notes, frequently alſo called *caroma*, and by us *quaver*.

FUSANA, in *Geography*, a town of Africa, in Tunis; 28 miles S.W. of Keff.

FUSANUS, in *Botany*, derived from *Fuſain*, the French name for Euonymus or ſpindle-tree, a genus of the claſs and order *Polygamia Monoecia*, and natural order *Eleagni*, Juſſ. 75.

Generic character. Hermaphrodite. Cal. Perianth one-leafed, turbinate, half five-cleft (four-cleft, Berg.); clefts ovate-acute, from flat ſpreading, with the tips gibboſe-uncinate, ſomewhat concave. *Cor.* none. *Stam.* Filaments four, linear, grooved in the middle, a little longer than the germ, inſerted into the calyx near it, and occupying the ſinus of it. Anthers roundiſh, compreſſed, four-lobed, erect. *Piſt.* Germ large, turbinate, almoſt inferior, wide at top, from flat ſomewhat concave, ſtriated, quadrangular, with four hollowed ſinuſes, each on each ſide of the germ ſolitary. Style thick, very ſhort, ſubquadrangular. Stigmas four, obtuſe, cruciform, ſmall. *Per.* Drupe.

Male. Cal. &c. as in the hermaphrodite, but the fruit abortive.

Eſſential character. Herm. Cal. five-cleft. *Cor.* none. *Stam.* four. *Germ* inferior; *ſtigmas* four. Drupe. *Male. Cal.* &c. of the former. *Fruit* abortive.

Species, 1. *F. Compreſſus*, flat-ſtalked F. Linn. Syſt. ed. 13. 765. Reich. 4. 330. Ait. Hort. Kew. 3. 433. Theſium Colpoon. Linn. Suppl. 161. Syſt. ed. 14. 250. Colpoon compreſſum. Berg. Cap. 38. t. 1. f. 1. A tree, with compreſſed and anticipital branches. *Leaves* oppoſite, obovate, blunt with a point, flat, quite entire, ſmooth, on ſhort petioles. *Racemes* from the axils of the branches, erect, compreſſed, ſcarcely longer than the leaves. The number of parts in the flowers four or five. The fruitful tree has a three-leaved involucre at the baſe of the germ with five glands. According to Juſſieu, it is a glaucous ſhrub, with oppoſite branches. The younger does not think it neceſſary to ſeparate it from the Theſiums. Juſſieu doubts whether it may not be more nearly allied to the Rhamni. A native of the Cape of Good Hope; introduced in 1756 by Mr. F. Maſſon. It is increaſed by cuttings, planted early in the ſummer in a good loamy earth, in pots, ſet in a glaſs-caſe or hot bed, ſhaded and watered gently till they have ſtruck root.

FUSARDE, in *Architecture*, a French word for an aſtragal, or ſmall convex moulding carved into beads.

FUSEADO, in *Geography*, a town of Naples, in Calabria Citra; 15 miles N.W. of Coſenza.

FUSEE, in *Horology*, is a mechanical contrivance for equalizing the power of the main-ſpring of a watch, chronometer, or portable clock, in all its different ſtates of tenſion. When a ſuſpended weight is uſed as the maintaining power of a clock, the cord, gut, or chain, by which it is ſuſpended, is wound round a cylindrical barrel, that has not the leaſt ſenſible variation in its diameter; on which account the ſuſpended power never varies in its intenſity, as it is wound off in its deſcent; in this caſe no contrivance is neceſſary for equalizing that power, which is already unvarying from its own nature. But a clock with ſuch a power is not portable, or at leaſt not conveniently ſo; a ſpring has therefore been adopted to ſupply the place of a ſuſpended weight in portable machines for meaſuring time, and as the power of all ſprings varies with its diſtance from the quieſcent poſition, the power derived from the force of a ſpring requires to be modified according to circumſtances, before it can become a proper ſubſtitute for a ſuſpended weight acting conſtantly, by means of its gravitation, with a ſlow and controlled velocity, ſo as to gain no acceſſion by acceleration. The firſt contrivance, we have ſaid in another place, was that which was denominated *ſtack-freed*, conſiſting of two ſprings, ſomehow oppoſing each other's action alternately, in a way that has never been well deſcribed; but the contrivance called the fuſee has been found of permanent uſe in practice, and conſequently merits a particular deſcription: we cannot, however, convey to our readers a clear idea of the nature and due conſtruction of the fuſee, without taking into conſideration, along with it, the main-ſpring, its box, and the chain that connects them. Theſe indeed

indeed, have been generally deſcribed under the articles CHRONOMETER and CLOCK; but as the theory, on which the ſhape of the fuſee depends, has not been adverted to, it is neceſſary that we ſhould treat the ſubject more particularly in this place.

The ſteel arbor, that paſſes through the ſpring-box, has a ſquare on its protruding end, on which a ſtrong ratchet-wheel is inſerted; and a catch, with a ſpring preſſing on it, ſcrewed to one of the plates of the frame of the works, always holds it faſt in any poſition given it; ſo that the box will turn freely, when urged round, without any motion in its arbor; upon this fixed arbor is a ſtud within the box, on which the interior end of the ſpring, intended for the maintaining power, is hooked, by a hole made near the extremity of the ſaid ſpring; while the exterior end of the ſame ſpring is pinned to the ſide of the box, the convex part of one ſuiting the concave part of the other, and the breadth of the ſpring being a gauge for the depth of the box. The diameter of the box depends upon the length and thickneſs of the ſpring conjointly; the ſtrength of the ſpring depends upon its breadth and thickneſs taken together, when of a given length; and the time it will continue to act at once coiling up, or winding, as it is called, will depend partly on its length, and partly on its ſtrength, for as the time in which the fuſee is made to revolve once muſt be guided by the whole time that the machine is intended to go at once winding, divided by the number of effective ſpirals or turns on the fuſee, when the ſpring is either too ſhort to admit of the requiſite number of turns to correſpond to the fuſee, or too weak to actuate the works for the whole time of going, the dimenſions of that ſpring will not anſwer the requiſite conditions, and muſt be changed for one of more ſuitable dimenſions. The relative forces of the ſpring when coiled up, and when nearly relaxed, muſt alſo be aſcertained by weights ſuſpended by the gut or chain, that is, wound round the exterior ſurface of the barrel; for on the ratio of theſe extreme weights, or powers, depend not only the relative diameters of the oppoſite ends of the fuſee, but alſo its actual length; the latter of which meaſures, we believe, is uſually taken at random, or agreeably to ſome propoſed model that has no dependence on, or connection with, the ratio of the extreme powers of the identical ſpring that is to be adopted; whereas an attention to the ratio in queſtion is a condition in the conſtruction, that it will appear preſently ought not to be diſpenſed with, particularly when the workmanſhip profeſſes to be of a ſuperior kind.

Conceiving now the main-ſpring coiled up in the box, (which operation requires a tool to force it properly in,) with the interior end faſt to the fixed arbor, and the exterior end pinned to the ſide of the box; let us ſuppoſe the gut, or chain, faſt alſo to the ſide of the box, near one of its ends, and wound a few times round the box, the outer end being at liberty; then, ſuppoſing the ſpring that is coiled to be in a comparatively relaxed ſtate, preſſing againſt the concavity of the box, with an effort calculated to unwind itſelf, in this caſe the central part of the box is not filled by the ſpring; pull now the free end of the gut or chain, ſo as to wind it from the box, while its faſt end prevents its ſlipping off without carrying the box round along with it, as many times as there are folds thereon, and, as the box is faſt to the exterior end of the included ſpring, this ſpring is thus brought round the fixed arbor that holds its interior end, and its folds are gradually brought up to fill the central part of the box, in which ſituation its intenſity is increaſed, in conſequence of its being moved from its quieſcent poſition: remit now the gut or chain, and the barrel will retrograde and wind on the folds again, while the included ſpring is relaxing itſelf gradually by a correſponding diminution of power, till it is again in its quieſcent poſition. Thus the power of the ſpring, contained in the box, is always diſpoſed to pull back the box itſelf whenever the hand, or any external force applied to the chain, has pulled it round in a forward direction.

Again, let us ſuppoſe the free end of the chain, that is ſpoken of as having been pulled, to be wound round a cylinder, placed in a frame parallel to the arbor of the box, and made faſt to its end, in ſuch a manner, that turning the cylinder round on the pivots of its arbor, will wind the chain round it while it is unwound from the box; in this caſe the incloſed ſpring is wound up as before, by being drawn towards the centre of its box; and provided its force were the ſame in all ſituations, or diſtances from the quieſcent point, the cylinder in queſtion would be a proper fuſee for the machine to be actuated by, after it had the great wheel attached to it, and the uſual ratchet for winding applied; but we have ſaid that the force of the main-ſpring is always varying as it relaxes itſelf, after it has been wound up to the centre of the box; therefore the cylinder muſt neceſſarily be ſo changed into another figure, that the place of action of the chain on its ſurface ſhall be more or leſs diſtant from its axis of motion, as the law of variation in the force of the main-ſpring ſhall demand, in order that the force tranſmitted to the train of wheel-work, and through it to the balance or pendulum, may be invariable, or very nearly ſo. It is obvious, from this view of the ſubject, that the figure of the body, ſubſtituted for the cylinder in queſtion, as a fuſee, muſt taper according to ſome certain law, either by ſtraight lines forming the fruſtum of a cone, or by curves of ſome order, bounding the ſides of the ſaid figure; and that the point of the chain's action ſhall recede from the axis of the fuſee's motion, as it revolves, in ſuch a way, while the force of the main-ſpring is diminiſhed by its relaxation, or departure from the centre of its box, that the product ariſing from the force of the ſpring, multiplied by the acting radius of the fuſee, ſhall be in every ſituation the ſame; for then the effectual power of the main-ſpring, as it regards the train, will be invariable. It can hardly be expected that the workman can determine the exact figure, and proportional diameters of his fuſee, by any mathematical rule that may be laid down from the meaſurement of the ſpring's extreme powers; but for the ſake of illuſtrating the theory of a fuſee's action more particularly, we will preſent the reader with ſome rules and calculations on this ſubject, propoſed by the late Benj. Martin, which are ſufficiently comprehenſive to take in all caſes. The figure of the curve, which will form the ſuperficies of the fuſee, by a revolution about its axis, may be inveſtigated as follows: Let B C D, in *fig.* 6. of *Plate* XXXVI. of *Horology*, be the curve, and A L the axis of the fuſee produced; let D be the point where the end of the chain is fixed on the fuſee, when the clock or watch is down, or the main-ſpring relaxed, and B the point where it lies when the ſpring is wound up: from the points B and D, let fall the perpendiculars B A and D H reſpectively to the axis A L, in which perpendiculars produced, let there be taken A E and H I proportional to the reſpective forces of the main-ſpring, when acting by the chain at the points of extreme power B and D; through the points E and I, let the right line E I K be drawn, till it interſects the axis produced at K, and from any point C on the curve, let C F be drawn perpendicular to the axis in the point G, then will F G repreſent the acting force of the ſpring when the chain is pulling it round on the point C. Now ſince the force acting on the firſt wheel of the train ought always to be uniformly the ſame, and as this force is always

always as the product or rectangle of the lines C F × G F, this given quantity may be made = $a\,b$, in which case we shall have F G = $\frac{a\ b}{\text{G C}}$. To determine, therefore, the equation of the curve B C D, let K H = a, H I = b, H G = x, and G C = y; then because of the similar triangles H K I and G K F, we have H K : H I : : G K : F G = $\frac{a\,b}{y}$; that is, $a : b : : a + x : \frac{a\,b}{y}$; whence we have $a\,a = a\,y + x\,y$, which is the equation of the curve, and which shews it to be that of the *hyperbola* with respect to the space between the curve and its asymptotes. Hence when $x = 0$, then $a = y$, or H K = H D; also when the point G arrives at A, then y = A B; and because E A × A B = I H × H D, we have E A : I H : : H D : A B : : a : y : : so is the greatest force of the spring upon the fusee to its least force. Again, because the ordinates H D, A B, &c. are at right angles to A L, the curve B C D is that called an *equilateral hyperbola*, by the revolution of which about its axis A K, or common asymptote, the true form of the solid or fusee is generated, as seen in *fig.* 7.

Our *fig.* 7. contains the substance of three figures, as given by Martin, and the letters of reference are altered, so as to prevent the recurrence of the same letters, which in the original account rendered the references very ambiguous to the reader; $\alpha\ \beta\ \gamma$, $\delta\ \varepsilon\ \zeta$, $\eta\ \theta\ \iota$, and $\varkappa\ \lambda\ \mu$, are so many opposite equilateral hyperbolas described about the asymptotes $\nu\ \xi$, and $o\ \pi$ intersecting one another in the centre ϱ. Put $\varrho\,\sigma$ [$= \sigma\beta$] = 1, then $\varrho\,\beta = \sqrt{2}$ = radius of the circle $\beta\ \theta\ \varepsilon\ \lambda$ touching the four equal hyperbolas in their respective vertices: again, $\varrho\,\tau = \varrho\,\upsilon = \sqrt{\varrho\,\xi^2 + \xi\,\upsilon^2} = 2$ is the distance of the focus of each hyperbola from the centre; and lastly, the parameter $a\,b = \theta\,\lambda$ the diameter of the circle, agreeably to the properties of the hyperbola. It is therefore plain, that the section of any given fusee, $\alpha\ \beta\ \theta\ \eta$, through its axis $\nu\ \xi$, is determined by two equal arcs $\alpha\ \beta$ and $\eta\ \theta$ of two equal and adjacent hyperbolas, beginning from their vertices β and θ. It is also evident, that, since $\sigma\ \beta$ and $\nu\ \alpha$ do represent the two extreme forces of the main-spring, in every fusee properly made, $\theta\ \beta$ and $\eta\ \alpha$ of the greatest and least ends thereof, must be exactly proportioned to the least and greatest force of the spring reciprocally.

It also follows, that when the proportion of the greatest and least force of the spring is known, or the ratio of $\sigma\ \beta$ to $\nu\ \alpha$ is given, then also the length of the fusee $\nu\ \sigma$ is a given quantity of a determinate length. Lastly, it is evident, that when the length of the fusee and one of the two forces $\sigma\ \beta$ or $\nu\ \alpha$ are given, then the other corresponding force is determinable, and not to be assumed at pleasure.

Having thus determined the geometrical form of the fusee, it may not be unacceptable to the reader to give an illustration of this theory by examples of the different cases. Let us therefore put $\sigma\ \beta = a$, $\nu\ \alpha = y$, and $\nu\ \sigma = x$, and then the equation $a\,a = a\,y + x\,y$ will appear in its proper form; whence if a and y be given to find x, we have $\frac{a\,a}{y} - a = x$; when x is given, or $x = 1$, we have given the ratio of a to y; for then $a\,a = a\,y + y$; consequently $a : y : : a + 1 : a$. When a and x are given, then $\frac{a^2}{a + y} = y$; and lastly, when x and y are given, we have $a^2 - a\,y = x\,y$, and, completing the square, $a = \sqrt{x\,y + \frac{1}{4}y^2} + y$.

The proper denominations for expressing the respective forces, a and y, of the main-spring, may be ounces and fractional parts, which we will suppose to be represented by so many tenth parts of an inch in the measures $\sigma\ \beta$, $\sigma\ \nu$, and $\nu\ \alpha$ of the fusee. These forces may be determined thus; let M N O P be the barrel containing the spring, and let Q N $\eta\ \alpha$ be the position or direction of the chain or gut upon the barrel and fusee when the spring is wound up; then, supposing the chain disengaged from the fusee, and carried under or behind the barrel, in the direction N Q M to the pulley R, so as to pass over and support the weight S in equilibrio, this weight will express the force of the spring in this situation. In like manner, if T $\theta\ \beta$ be the chain when the spring is down or relaxed, and it be detached and carried under the barrel, in the direction O T P, to the pulley U, so as to pass over it, and to support the weight V, which is just large enough to balance the smallest force of the spring, then $\sigma\ \beta = a : \nu\ \alpha = y : :$ S : V.

Case 1.—Suppose the weight S to be 63 ounces, and the weight V to be 21; then a = 63 and y = 21; or, which is the same thing, a = 3 and y = 1; hence we find $x = \frac{a\ a}{y} - a = 6 = 2\,a$, that is, when the extreme forces are 3 : 1, the length of the fusee $\nu\ \sigma$ is equal to the diameter of its base or thick end $\beta\ \theta$. When S : V : : 2 : 1 : : $\sigma\ \beta$: $\nu\ \alpha$, then $x = \alpha$, or $\sigma\ \nu = \sigma\ \beta$; also when S : V : : 3 : 2, then $x = \frac{1}{2}\,a$; and universally if S : V : : m : n : : a : y : : $a + x$: a, then it will be $\frac{m - n}{n}\,a = x$.

Case 2.—Given the length of the fusee $\sigma\ \nu = 6$, to determine the ratio of the forces or weights S, V, which will give the diameters $\theta\ \beta$ and $\eta\ \alpha$ of the opposite ends of the fusee. Since $a^2 = a\,y + 6\,y$ agreeably to the laws of the hyperbola, we have $a : y : : a + 6 : a$; then by assuming the value of a we have that of y thus; suppose a = 3, then $a : y : : 3 + 6 : 3 : : 3 : 1$; and in this case the diameter $\theta\ \beta$ is three times the diameter $\eta\ \alpha$; and because $a : y : : m : n$, therefore for any assumed ratio, we have $\frac{n}{m - n}\,x = a$; thus if $m : n : : 2 : 1$, then $x = a$; or if $m : n : : 3 : 2$, then $2\,x = a$; consequently if $x = 6$, we have a = 12, and y = 8.

Case 3.—Given the length of the fusee, and the greatest force of the main-spring to find the least force of the same. Suppose $x = \sigma\ \nu = 6$, and $a = \sigma\ \beta = 3$, then $y = \frac{a^2}{a + x} = \frac{9}{9} = 1$; so that if S = 63 ounces, we have V = 21; and if $x = a$, then $y = \frac{1}{2}\,a$, or $\theta\ \beta = 2\ \eta\ \alpha$.

Case 4.—Given the length of the fusee, and the least force of the main-spring, to find the greatest. Let x = 6, and y = 1, then $\sqrt{x\,y + \frac{1}{4}y^2} + \frac{1}{2}\,y = \sqrt{6.25} + 0.5 = 3 = a$, so that if y = 21 ounces, the greatest force will be a = 63: therefore, in every case, the form and dimensions of the fusee are, or may be, geometrically determined.

But we have yet to shew how the requisite hyperbola $\alpha\ \beta\ \gamma$ may be described, as a pattern for the curve of the fusee. Suppose the extreme forces of the main-spring to be, as we have before assumed, as 63 to 21; then having drawn two lines $\nu\ \xi$ and $o\ \pi$ to intersect at ϱ at right angles for asymptotes, let the angles $\nu\ \varrho\ \pi$ and $o\ \varrho\ \xi$ be bisected by the right line $\tau\ \varrho\ \varepsilon$, continued each way indefinitely. Then having determined the diameter of the base $\theta\ \beta$ of the fusee, take that extent in the dividers, and set it off each way from the centre ϱ in the line $\tau\ \varepsilon$ to τ and ϕ, which points will be the foci of the two opposite hyperbolas $\alpha\ \beta\ \gamma$ and $\delta\ \varepsilon\ \zeta$. In the focus ϕ fix a ruler $\phi\ \chi\ \downarrow$, so as to be moveable round a pin as a centre at ϕ; then take a thread, as much shorter

than

than the ruler as is equal to the diameter $\beta\,\varepsilon$ of the circle $\beta\,\theta\,\varepsilon\,\lambda$, and make one end of it faſt to the end, $\downarrow$, of the ruler, and the other to a pin fixed in the other focus τ; then a tracer ſtretching the ſaid thread, at the edge of the ruler at any point χ, will trace the required hyperbola, while the ruler is made to turn on its centre of motion φ; for in every caſe the difference of the two lines $\downarrow\chi$ and $\tau\,\chi$, taken from any point x in the deſcribed curve, will always be equal to the diameter $\beta\,\varepsilon$, agreeably to the laws of the hyperbolic curve. When the proper curve is thus formed on paper, for any particular main-ſpring, it may be transferred to card-paper, or ſheet-braſs; as a pattern or gauge to be applied to the fuſee-engine, as will be hereafter deſcribed.

FUSEE-*engine* is an engine contrived for cutting the ſpiral groove, that winds round the ſolid part of the fuſee, which is formed, as we have ſhewn above, by the revolution of an hyperbolic curve. Various conſtructions of this uſeful engine have been deviſed by different ingenious workmen, but it would be difficult to trace each modification to its reſpective inventor, nor indeed is it a matter of much importance, as the general principle is the ſame in all, namely, the application of a ſliding cutting tool to the ſurface of a revolving fuſee; the different methods of adjuſting and limiting the velocities of the moving parts of the engine, and a proviſion for the ſteadineſs of thoſe motions, have given riſe to various applications of the mechanical powers to produce the ſame ultimate effect. We ſhall lay before our readers a few varieties of the engine in queſtion, ſuch as we deem the moſt uſeful in practice, from an examination of which, it will be obvious to the mechaniſt, that other combinations, to anſwer the ſame purpoſe, might be deviſed without difficulty.

1. *Fuſee-engine acting by means of an inclined Plane.*—The firſt fuſee-engine that we propoſe to deſcribe, and that which, in our eſtimation, is the ſteadieſt in its action, is repreſented by *fig.* 1. of *Plate* XXXVII. of *Horology*, and is that which was formerly uſed by the late Brower, whoſe cutting engine we deſcribed as made by Hindley of York; and we have reaſon to believe that the fuſee-engine before us was contrived by the ſame ingenious mechaniſt. A A is a ſolid block of hard wood, that may lie on a table, or have feet of its own, to ſupport it: B B are two firm iron ſupports ſcrewed to the ſaid block, and bearing the ſtrong triangular bridges C, C; through theſe triangular bridges paſſes a long priſm of ſmooth iron, the end of which is ſeen at D; upon this ſtrong priſm ſtand three upright iron, or ſteel, pieces E, F, and G, formed like the puppets of a lathe, the laſt of which is moveable at pleaſure, and the whole taken together conſtitute a frame very much reſembling that of a lathe: H we will call the mandril, or arbor, that paſſes through circular holes in the puppets E and F, and has a winch, I, to be turned by; the cylindrical piece of ſteel, K, paſſes through the puppet G, and is fixed at any depth in the hole by the lever and ſcrew L, over it, which ſcrew enters the head of the puppet, and preſſes againſt the convex ſide of K, the inner end of which is pointed by a cone, and its outer end has a conical hole drilled in it, by which means the piece, K, may be made to bear either againſt a hole, or a point in any arbor that a fuſee may happen to have; M is a lever with a projecting pin ſcrewed to the interior end of the mandril, ſo as to revolve with it, and the arbor of the fuſee, O, which bears againſt a cylindrical hole at this end of the mandril with one end, and againſt the cylindrical point of piece K with the other, carries a ſecond lever N, ſeen ſeparately in *fig.* 2, which correſponds to what is called a *dog* in a turning frame; this dog is fixed to the arbor of the fuſee, by a ſmall thumb-ſcrew at its lower end, as ſeen in *fig.* 2, and the oblong hole at its upper end receives the projecting pin of lever M, ſo that when this lever revolves with the mandril, the dog and fuſee are carried round at the ſame time. On the projecting parts, P, P, of the puppets, F, G, which have each a triangular hole, is ſupported a ſecond, but a ſmaller priſm, Q, of iron, or ſteel, that may be fixed in any poſition, to the right or left, by ſliding without ſhake in the two triangular and diſtant holes above-named: to this priſm, Q, is fixed a ſliding perforated piece, R, by means of a thumb-ſcrew ſeen under Q, and at right angles to this ſliding piece, R, is fixed faſt a third ſtill ſmaller priſm, S, which conſequently may be fixed over any part of priſm Q, ſo as to be oppoſite the fuſee O, or any part of it; along this third priſm, S, ſlides the upright bearer T, that may alſo be fixed at any diſtance from the end of S by another thumb-ſcrew, which appears under it; the bearer, T, therefore ſlides alſo along the ſecond priſm, Q, whenever the piece, R, is moved in making the adjuſtment for poſition; at the top of this bearer is a ſquare hole of conſiderable depth, in which the cutting tool, U, ſlides without ſhake, and any ſlight preſſure on the handle at U of the cutting tool will apply its cutting point to the ſurface of the revolving fuſee, the winch, I, being turned at the ſame time; but the tool U, or the fuſee, muſt one of them have a lateral motion, otherwiſe the groove cut by the ſaid point would form a circle only on the ſurface of the fuſee; to render the groove ſpiral, therefore, is the buſineſs of the remaining portion of the apparatus.

W X Y Z is a long metallic frame with its ſides made perfectly parallel, ſo as to ſlide without ſhake within the two fixed parallel bars of metal, *a a* and *b b*, which are ſcrewed to the puppets E and F; this frame is counterbalanced by a weight ſuſpended by a ſtring, not ſeen in the figure, that is faſtened to its ſuperior end, before it paſſes over a fixed friction-wheel, not neceſſary to be exhibited; and on the mandril, behind this frame, is a pinion inſerted that acts with the rack, or toothed bar, that is viſible at the middle of the lower part of the frame, to which it is made faſt; hence, whenever the winch, I, is turned, not only the fuſee revolves, but the frame, W X Y Z, aſcends or deſcends, accordingly as the turns are made direct or retrograde: *c d e* is a metallic bar, ſimilar to one of the bars that conſtitutes the ſides of the frame, and is moveable round a pin at *d*, as a centre of motion; the extreme croſs-pieces or end pieces of the frame have each a circular perforation quite through, large enough to admit each a ſcrew through them, of which the milled nuts are viſible near W and Z reſpectively; it is obvious, therefore, that this bar, *c d e*, may be fixed either parallel to the ſides of the frame, or at any given angle of inclination, within the limits of the circular apertures, the edges of which are, or may be, graduated; for when the bar is turned round its centre from its parallel poſition, as in the figure, the thumb-ſcrews will act on its extreme ends, and ſet it faſt. Laſtly a weight, V, is ſuſpended by a cord, going round a fixed friction-wheel on the cheek *a a* of puppet E, and made faſt to the ſecond priſm, Q, at the end near R, ſo as to pull this priſm, and ſurmounted cutting tool, U, towards the inclined bar of the frame, till an elaſtic croſs-bar, *f f*, attached to the end of the ſaid priſm, comes in contact with the ſtraight edge of the inclined bar, in which ſituation the priſm in queſtion will remain at reſt while the frame is at reſt; but when the frame is made to aſcend by the pinion of the winch, the weight, V, preſerves the contact of the elaſtic bar, *f f*, with the ſide of the inclined bar, and deſcending, pulls after it the priſm Q, with its cutting-tool,

the fuſee, in the mean time, being made to revolve; it is evident, therefore, that if one hand of the workman turn the winch, I, while the other is preſſing gently againſt the handle, U, of the cutting-tool, a groove will be made on the ſurface of the fuſee of ſome determined number of revolutions, which ſhall depend on the quantity of the bar's inclination, that regulates the motion of the priſm; and as this inclination is adjuſtable, a given number of ſpiral turns may be aſſigned by adjuſtment, to a given length of the fuſee to be cut. At the ſame time, as the fuſee is not cylindrical, the regulation of the preſſure by hand only muſt be very nice, to make the tool cut the groove of equal depth in every part of the ſucceſſive revolutions, where the diameter is continually varying its dimenſions. To obviate any inaccuracy that is liable to ariſe from this operation, the French have applied a piece of metal formed into the proper hyperbolic curve, as a guide, or gauge, for the run of the cutting tool, ſuch as is repreſented by *fig.* 3, which we will deſcribe as adapted to our preſent engine, though it was applied, according to F. Berthoud, by M. Lelievre to an engine, contrived by him, of a conſtruction nearly ſimilar to the one we are deſcribing, except that the ſliding frame moved horizontally, whereas our's moves vertically.

In the figure laſt named, A B is a braſs frame, carrying the cutting tool U, and its ſupporter T, adapted to the priſm Q, in *fig.* 1; but at C, where the cutting point is connected with A B, is a piece of metal formed into an hyperbolic curve, as ſeen detached at D, near the ſaid figure; this curve, or gauge, is formed by the rules laid down in our preceding article FUSEE, and is fixed by a clamping piece, E, with a thumb-ſcrew at the required poſition, as to depth, while the ſcrews at the ends of A B adjuſt the lateral poſition, for the length of the fuſee, by means of the oblong holes that allow the whole frame of this figure to ſlide to the right and left, as occaſion may require, before it is finally fixed for action. In this ſituation of the apparatus, a pin is inſerted faſt into the ſtem of the cutting tool near C, ſo as to be in contact with the edge of the curve; the conſequence of which contrivance is, that while the cutting tool goes along with the priſm Q, in *fig.* 1, as before deſcribed, the pin, reſting againſt the edge of the fixed curve, is puſhed outwards at the ſame time that the tool advances in a lateral direction, along the ſide of the fuſee, and the bottom of the ſpiral groove thus cut is gauged to a given depth, depending not on the ſhape of the fuſee itſelf, but of the hyperbolic curve at the edge of the ſmall plate, C, which in fact forms the fuſee, at the ſame time that it is grooved by the cutting point. This contrivance has not, that we know of, been uſed in England, notwithſtanding its ingenuity and practicability, and the reaſon may be, that, as we have obſerved before, every particular ſpring, uſed as a main-ſpring, requires its own appropriate curve, and it would be endleſs to have a curved piece made for every ſeparate fuſee that is to be cut by the engine: beſides, a ſpring is rarely found uniform in its variation of force with the variation of tenſion, throughout its whole time of unwinding; ſo that, after all, tentative adjuſtments of the depth of certain ſpirals, to correſpond to the actual force of the ſpring, at the ſeveral ſtates of relaxation, become neceſſary, to enſure an uniformity of the ſpring's influence on the train of wheel-work: the tool which our Engliſh watch and clock-makers uſe, to aſcertain the proper dimenſions of the fuſee, when formed and grooved, has been already deſcribed among the other CLOCK *tools*, and may be ſeen at *fig.* 10. of *Plate* XXI. of *Horology*; and when any particular part of the fuſee requires to be diminiſhed, or to have its groove deepened, the fuſee is put either into a common turning frame, or into the FUSEE *frame*, hereafter deſcribed, (*fig.* 3. of *Plate* XXXVIII.) and the cutting point is ſuffered to run by the guidance of the groove already formed, till the given part is found deep enough, after a repetition of trials, made with the ſpring properly fixed, as to tenſion, and wound up to the given part of the fuſee that has been altered. Thus every point in the ſpiral groove of a fuſee may be adjuſted to the acting force of the ſpring with which it is to be uſed; and we beg leave to repeat, that theſe adjuſtments of the fuſee, by trial of the fuſee-tool, ought never to be omitted when a new main-ſpring is firſt uſed in any watch or clock, however old; for as ſoon might we expect that the expanſion of mercury, in a new tube, would correſpond to an old ſcale previouſly made, as that a new main-ſpring ſhall have its extreme and intermediate forces exactly compenſated by an old fuſee without new adjuſtments.

2 FUSEE-*engine acting by the union of a ſcrew, a double lever, and a pair of wheels.*—The fuſee-engine which we now come to deſcribe unites the combined powers of wheel-work, the ſcrews, and the double lever, to modify the reſpective motions of the fuſee and of the cutting tool, in the following manner; A B, in *fig.* 4. of the laſt plate, is a plate of braſs fixed, or otherwiſe placed on a table, during the act of uſing the engine now before us; C C and D D are two pair of puppets, reſpectively ſcrewed to the plate A B, and united reſpectively by the edge-bars lying on the ſaid plate; the little frame under *fig.* 5, ſeen there detached, is ſcrewed on the ſame plate A B, between the two edge-bars, to which it will ſlide parallel, before it is fixed by its thumb-ſcrew beneath; this ſmall frame receives the fuſee between its cylindrical holding pieces E and F, and the piece E is moreover uſed as a ſtud for a looſe wheel to revolve round; a pin projecting from the plane of this wheel impels a dog, as in our laſt engine, fixed on the fuſee-arbor, to which it communicates motion whenever the wheel revolves; this wheel is impelled by another, placed faſt on the tapped arbor, of the winch I, that fits in a hole made in the puppet C, near the winch, and is ſupported at the other end by a cylindrical piece with a conical point, entering the hole of the other puppet C; whenever therefore the winch is turned, both wheels and the fuſee will all revolve, though not all in the ſame direction, nor yet in the ſame time, unleſs the two wheels have like dimenſions and numbers of teeth. The perforated cylindrical piece G, which if tapped to receive the ſcrew of the arbor, is prevented from turning round, as the arbor revolves, by a projecting piece below it, that ſurrounds a fixed ſtrong wire H K, which ſlides, or is at liberty to ſlide, in two cocks ſcrewed to the puppets C and C, as ſeen in the figure; therefore, when the arbor containing the male ſcrew revolves, by means of its winch, the piece G, with the correſponding female ſcrew, is drawn towards the winch gradually, and the regularity of this motion will depend on the due inclination of the threads of the ſcrew, which therefore ought not to be *drunk*, as the workmen call the imperfection in this reſpect; but the piece G would be at liberty to travel along the whole length of the arbor, if there were no ſtops at the limited diſtances: to obviate this, the wheel on the tapped arbor has a pin alſo projecting from its plane, and the two ſliding pieces L and M will clamp at any given points of the wire juſt deſcribed; near the laſt named wheel the wire is cranked ſo as to permit the wheel to paſs through its crank in its preſent poſition, but when the piece under G ſlides along the wire till it meets with the clamp L, it puſhes the wire altogether before it, till the angular part of the crank falls in the way of the wheel's pin, when all further motion is arreſted by the locking of the wheel; a contrary motion will alſo lock the

wheel

wheel by a pin behind the wheel, when the clamp M is acted on, and the diſtance of the clamps muſt depend upon the length of the fuſee to be cut, as we ſhall ſee more clearly preſently. Above and below the moveable piece G are fixed two ſtrong wires N and O, which running parallel to each other, are ſo fixed, by a pin paſſing along ſocket P, that they have thereon one common centre of motion, in the manner of a long joint; this ſocket is attached to the double lever, ſeen detached at *fig.* 6, with five holes near its centre, and with a ſimilar ſocket at its oppoſite end; the cock, which is ſeen in *fig.* 7, is fixed by a ſcrew and ſteady pin to the bottom plate A B, beyond the ſmall frame E F, and ſupports the double lever P Q, by a pin placed in ſome one of its five holes, accordingly as the oppoſite ends of the lever are to be proportioned to each other, that is, accordingly as the central pin is inſerted into the firſt, ſecond, or third, &c. hole of the double lever. R is a long bar, of equal breadth throughout, that ſupports the cutting tool S, and that is at liberty to ſlide within the puppets D and D without ſhake; another pair of ſtrong wires, like N and O, are made faſt to this bar above and below, which wires have alſo their common centre of motion round a long pin, paſſing through the ſocket Q, at the oppoſite end of the double lever.

From this arrangement it is evident, that whenever the piece G is drawn towards the winch, by the revolution of the latter, the wires N and O will make their end of the double lever follow; but as the oppoſite end of the ſaid lever will move in a contrary direction, its wires will draw back the long bar R, and with it the cutting tool, the fuſee in the mean time being revolving; hence it is obvious that a little preſſure on the handle S of the cutting tool will form a ſpiral groove, ſuch as was deſcribed when we detailed the operations of the laſt engine. The number of turns on the fuſee may be limited either by altering the central pin between the oppoſite levers, or by changing the wheels for others of different ratios, with reſpect to their diameters and numbers of teeth, or by both jointly when great nicety is required. We are diſpoſed to think that the variety of fittings in this conſtruction, and the union of different powers, are not calculated to render the motions to be produced equally ſteady, particularly when the parts of action have been a little looſened by uſe.

It may not be improper to ſubjoin here another method of applying the cutting point to the fuſee, which ſeems calculated to prevent parallax or lateral motion of the point; R, in *fig.* 8, as in *fig.* 4, is the edge-bar bearing the cutter D fixed faſt to the upright lever B; this lever is faſt on the arbor A, which turns on two pivots at the cocks *a* and *a* fixed to the bar R; then ſuppoſing D to have a handle like S in *fig.* 4, the motion of the arbor A round its pivots will allow the cutting point to approach, or recede from the fuſee, according to the quantity of preſſure applied to it in the act of cutting. This conſtruction is not ſo common as that in *fig.* 4, but muſt be more ſteady, and would probably cut better if there were a joint where D is made faſt to B, to preſerve the horizontal poſition of the cutting-tool as it recedes or advances.

3. *Fuſee-engine* (*common*) *acting by the union of one ſcrew and two ſingle levers.*—The fuſee-engine repreſented in *fig.* 1. of *Plate* XXXVIII. of *Horology*, is the common engine taken from one of the Lancaſhire pattern-books, and is the moſt ſimple of any; A B C D is a plate of braſs, on which the dove-tailed plate E F ſlides without ſhake, and with but little friction, the ſides being perfectly parallel. The axis of the handle is ſupported by the bearing pieces A and G faſt to the under plate, and has a ſcrew cut on it throughout its length between the ſaid bearing pieces; the thick end H of the lever H I is tapped ſo as to receive the ſcrew of the axis without ſhake, to which it can be adapted by the ſcrew at H; this lever has an oblong aperture through it, in the direction of its length from H nearly to I, and is moveable round the pin at K, that enters the lower plate through a ſecond aperture at the extreme end of the lever; L M is a ſecond lever, turning on the pin M fixed to the ſliding plate, and ſet faſt by the milled nut L, over any point of the circular aperture N, as the inclination may require; O L is an endleſs ſcrew of ſlow motion, for regulating the accuracy of the adjuſtment to the point where the nut fixes the lever; and T is a pin fixed in the lever L M, that paſſes through the oblong apertures of lever H I, and gives motion to the ſliding plate E F, whenever the handle turns the axis of the ſcrew, and as the cutting point P Q is attached to this plate, by the cocks R and S, it alſo moves with the ſame velocity; this velocity depends on the diſtance of the pin T from K the centre of its motion, and may therefore be regulated by the nut L and ſcrew O L, to the requiſite angular velocity, that may ſuit each turn of the handle, or fuſee attached to it by a clamping piece between G and D.

The operation of cutting the fuſee by this engine, it is preſumed, can require no further explanation.

4. *Fuſee-engine* (*old*), *acting by the union of a wheel and pinion, a ſcrew, a ſimple lever, and a ſliding frame.*—*Fig.* 2, of the laſt plate, exhibits a perſpective view of the old fuſee engine as given in the Lancaſhire pattern books; A B C D, as before, is the inferior frame, and E F the ſliding frame, but inſtead of dove-tailed edges this upper frame ſlides by means of four cylindrical pieces paſſing through correſponding holes in the edges of the lower frame, as ſeen in the figure; there is alſo an axis formed into a ſcrew, turned by the handle, acting in the part H of the inviſible lever H I, as before, which lever lies here under the frames; but a wheel G on a ſeparate axis, that carries the fuſee, is actuated by a pinion on the axis of the handle. The ſecond lever L M of the preceding engine is here wanting; but the nut T is in place of its pin T, and penetrates one of the circular holes in the ſuperincumbent piece R T, ſo as to lay hold of the lever H I through a concealed aperture in the ſliding frame E F; the diſtance of the hole uſed from the centre of the lever's motion K regulates the velocity, as before, of the ſliding frame, and conſequently of the cutting point P Q, ſcrewed to it by a pair of embracing cocks, while the ſcrew, taking into the nut R, adjuſts the exact ſituation of the hole occupied by the milled nut T. In all other reſpects the operation of cutting the fuſee is the ſame as in the other engines. Sometimes we have ſeen a ſcrew acting againſt the ſliding frame and placed between the cylindrical pieces on the inner edge of the under frame to prevent jerks, but when the ſcrew and other acting parts are well fitted, this is unneceſſary. From theſe four engines it is eaſy to perceive, as we have obſerved, that various other modifications may be adopted to anſwer the ſame purpoſe.

Fusee *Frame.*—When a fuſee has been cut by an engine, and is found on trial to have ſome place or places of too large a diameter for the main-ſpring to act equally with, a little frame, like that in *fig.* 3. of the laſt plate, is ſometimes uſed, where the cutting tool A has its point put in the ſpiral groove, and is made to reſt on a cylindrical arbor B, that reſts on the equal rollers C and D, fixed in the reſpective ends of the frame, by means of a grooved pulley, ſo that as the fuſee revolves, the ſaid arbor B moves laterally, and keeps the point of the cutting tool in the groove, at right angles to the arbor of the fuſee, and thus any particular part only of the fuſee may be reduced, by partially turning the handle, as the circumſtances of the caſe may require.

FUSEE, *Fuze*, or *Fuſe*, in *War*. See FUZE.

FUSHENG, in *Geography*, a town of Perſia, in Choraſan, 36 miles N. of Herat.

FUSIBILITY, that quality in metals and minerals, which diſpoſes them for fuſion.

Gold is more fuſible than iron or copper; but leſs ſo than ſilver, tin, and lead.

Borax is frequently mixed with metals, to render them more fuſible.

FUSIFORMIS, RADIX, in *Botany*, a ſpindle-ſhaped root, as in the carrot, parſnep, and radiſh. See ROOT.

FUSIGNANO, in *Geography*, a town of Italy, in the department of the Lower Po; 24 miles S. E. of Ferrara.

FUSIL, in *Heraldry*, by the French called *fuſee*, q. d. ſpindle, is a bearing of a rhomboidal figure, more ſlender than the lozenge; its upper and lower angles being more acute than the two middle ones.

FUSIL, in *Military Language*, is a light muſket, nearly ſimilar to a carabine, but in general more neatly finiſhed; it being uſually intended for the uſe of officers attached to light companies, and thoſe appertaining to fuſileer corps, to yagers, rangers, chaſſeurs, carabineers, and others in which light arms are uſually employed. Formerly the officers attached to grenadier companies bore fuſils, but within theſe few years that practice has been diſcontinued, nor do many officers in any corps uſe them; ſwords being the only weapons ordinarily borne. The fuſils intended for officers are generally mounted with ſilver, and have bayonets of a light conſtruction; the bore uſually calculated for balls of eighteen to the pound, and the length of the barrels from thirty-four to thirty-eight inches. We conſider the fuſil as being an eligible weapon for all officers whoſe duty it may particularly be to engage in deſultory ſkirmiſhes, and eſpecially in that horrid ſpecies of warfare, termed "buſh-fighting," but for the ordinary branches of ſervice performed by regiments of the line, they are certainly ill calculated, on account of their being cumbrous, and a check upon thoſe active ſervices connected with the preſervation of order, and the prompt execution of whatever evolutions may be performed. The eſpontoon, though by no means a choice implement, is certainly more efficient in keeping the muſkets down to a proper level, while it furniſhes no inſignificant means of defence, eſpecially againſt a ſingle horſeman. For the ſame reaſon no ſerjeants ſhould bear fuſils; halberts being in every inſtance ſuperior. We underſtand from good authority that non-commiſſioned, and ſometimes even commiſſioned officers who bear fire-arms, do not attend ſo much to the preſervation of diſcipline, as they do to the taking aim with their fuſils, wherever opportunity offers for "taking a good ſhot."

FUSIL-*man*, commonly called *fugle-man*, is a non-commiſſioned officer or ſoldier, whoſe duty is to give the time for the ſeveral motions of the firelock, the facings, &c. performed by any body of men. His poſt is uſually in front, commonly towards the right flank; but common ſenſe points out that it ſhould always be more centrical, eſpecially for whole regiments, the rear ranks of which are often compelled to perform their motions partly by gueſs, and partly by a rapid adaptation of what they ſee doing by the front rank. This inconvenience is neceſſarily increaſed in proportion to the obliquity or deviation from a central poſition.

The motions of the fuſil-man ſhould, in contradiſtinction to thoſe of the ſoldiers in general, be broad, open, and ſtrongly marked. The quitting of a hand ſhould be denoted by forcibly throwing the reſpective arm upwards, and wide from the body; and the joining a hand ſhould be denoted by the reverſe, that is, by throwing the correſponding arm forcibly towards, or acroſs the body. The motion of a foot ſhould be on a ſimilar principle, and all facings ſhould be marked by firſt raiſing the right hand and throwing back the right foot, then as the body caſts round, reſtoring them with a ſweeping motion to their places. Without ſuch demonſtrations, which certainly appear individually ludicrous, no corps could go through their motions with exactneſs.

FUSILE COLUMN and MARBLE; ſee the ſubſtantives.

FUSILEER, in *Military Language*. This deſignation ſhould literally apply to men bearing fuſils, but it is in many inſtances given to regiments which vary but little from the ordinary claſs of regiments of the line. The duties of a fuſileer, properly ſpeaking, are chiefly directed to the ſame ſervices as appertain to light infantry, and to the ſeveral corps performing the more deſultory and detached operations of a campaign; conſequently the dreſs ought to be ſo faſhioned as to allow perfect freedom of motion, and not to be ſubject to hitching among boughs, &c. The colour ought to conform to the general face of the country; thus, where much verdure prevails, green ſhould be adopted; but where the ſoil is generally barren, any medium ſhade of brown, or of ruſſet, or of olive colour, will be preferable; ſince ſuch will tend beſt to the concealment of thoſe who may be ordered to occupy, poſſeſs, &c. for the purpoſe of ſurpriſing, or of annoying an enemy. Fuſileers ſhould wear ſtout ſhoes, with whole gaiters of ſubſtantial but very pliant leather, reaching over the knees, double-milled pantaloons and jacket, without any facings, or glittering buttons; the belts ſhould be of the ſame colour as the cloth, as ought alſo the cap, which ſhould be of leather, with flaps to let down both before and behind: every article ſhould be water-proof, and made to fit very compactly, but without deteriorating the freedom of motion. The fuſil and the bayonet ought to be browned over all thoſe parts uſually kept bright; in order that no rays ſhould be reflected from them. This mode is now very properly becoming very general in the Britiſh ſervice, and carries with it the important recommendation of conſiderably diminiſhing thoſe minor duties of the ſoldier which often cannot be executed, and when they can, rarely fail while on active ſervice to trench upon the little reſt he may occaſionally be able to obtain.

FUSILUS, in *Botany*, a name given by ſome to the fuſanus, a more common name for the euonymus.

FUSILY, or FUSILE, in *Heraldry*, is when a field, or ordinary, is entirely covered over, or divided into fuſils.

FUSINI, in *Geography*, a town of Japan, in the iſland of Niphon, 16 miles S.E. of Meaco.

FUSION, the ſolution or melting of metals, minerals, &c. by means of fire; or the act of changing them from their ſolid ſtate to a fluor.

The word is derived from the Latin, *fuſio*; of *fundo*, *I pour out*. Whence, alſo, *effuſion*, *infuſion*, *ſuffuſion*, and *transfuſion*; which ſee.

To give the ore its metallic form, they fuſe it; when it is in fuſion, the metalline ſubſtance, being the heavieſt, ſinks to the bottom of the furnace; the other terreſtrial matters riſing, in form of ſcoria, to the ſurface.

It is commonly imagined, that the fuſion and metalline form of ores is wholly the effect of fire; and we have theories of fuſibility founded on this principle; but it is a miſtaken one. Fire, no doubt, is the principal agent; but fire, alone, is not ſufficient. A mineral, or piece of metal not purified, being put alone in a crucible, melts with great difficulty, and never becomes a perfect metal; copper ore, for inſtance, being thus applied, its impure part forms a

ſcoria,

ſcoria, and vitrifies; the metalline part reſiding at bottom, under the appearance of a black regulus. To promote the fuſion and ſeparation, they mix coals, or ſtones, or cinders, or old ſcoriæ, along with the ore; the inflammable principle in which, by help of fire, fuſes them perfectly, ſets the heterogeneous part at liberty, and raiſes it to the top. See FLUX.

The general reaſon of fuſion is pretty eaſily aſſigned. The firmneſs or ſolidity of a body ariſes from the force wherewith its particles cohere. And the coheſion of all bodies is as the quantity of contact in the component particles.

Now the corpuſcles of fire, entering with rapidity into the pores of the metal, agitate, and, by degrees, looſen, divide and diminiſh their contact; till at length there is not enough to hinder their rolling over each other, and giving way upon the leaſt impulſe.

The dilatation obſervable in all fuſion, is a proof that the particles of the bodies are ſeparated, and ſet at a diſtance from each other; and, conſequently, their contacts and coheſions diminiſhed.

In effect, rarefaction and dilatation are the neceſſary conſequences of fire and heat.

From the difference of coheſion proceeds that variety we obſerve in the fuſion of bodies; for ſuch as have leaſt contact of parts, ſooneſt give way to the fire; and ſome will melt away by the warmth of a vapour only: thus air and mercury are ſo fuſible, that the heat of the atmoſphere is always ſufficient to keep them fluid; when others, which have a ſtronger contact, are not to be ſeparated without much difficulty. Upon this account, vegetables very eaſily diſunite, minerals ſlower, and metals ſloweſt of all; and of the laſt, thoſe wherein the contact of parts is leaſt, as in lead and tin, moſt readily melt; but thoſe which are moſt compact, as gold and ſilver, are not to be managed but by a violent heat.

If now the force of coheſion were proportional to the quantity of matter, or to the weight of bodies, we might from ſtatics account for all the variety that occurs in fuſion: for by knowing the ſpecific gravity of a body, we ſhould then know what force is required to melt it; but becauſe the ſame quantity of matter may be ſo variouſly diſpoſed, that in one body there ſhall be a much greater contact than in another, though the gravity be equal, or even greater in the latter, therefore the force of the coheſion cannot be eſtimated by gravity; for lead, though more ponderous than all other metals except gold, yet in the fire is more eaſily melted than almoſt any other; ſo that it neceſſarily follows, that in this metal there muſt be a leſs coheſion, or contact of parts, how much ſoever it may exceed others in the quantity of its matter.

Bodies after fuſion return again into a ſolid maſs, upon removing them from the fire; becauſe their particles hereupon approach nearer to one another by their attractive force, and are compelled to unite.

Such as conſiſt of homogeneous and unalterable parts, as wax, gums, and the purer metals, recover their ancient form: for when the ſame texture of parts remains in the whole body, it muſt of courſe re-aſſume the ſame appearance, when the ſeparating power ceaſeth to act; but other bodies whoſe parts with reſpect to denſity and ſurface are extremely different from one another, while ſome are carried off by the force or heat, and others are changed as to figure and poſition, muſt be forced to appear in another form; for they cannot recover their original phaſes, unleſs every particle could reinſtate itſelf in that very ſituation it had before, which may be hindered infinite ways; as may be experienced eaſily in heterogeneous bodies.

The difference, therefore, obſerved even in homogeneous bodies after liquefaction, is no ways to be accounted for but from the changeableneſs of ſurface in their parts: for thoſe bodies whoſe parts conſtantly retain the ſame ſurfaces never loſe their form; but others, by having the ſurfaces of their parts altered, have a different texture, and put on another appearance.

It had been formerly an opinion, very generally received, that the ſolution of metals by lightning is effected by a kind of cold fuſion; and the inſtances that have been uſually alleged in ſupport of this opinion, are thoſe of a ſword being melted in its ſcabbard, and of money being melted in a bag, whilſt the ſcabbard and bag remained unhurt. But it appears, by a variety of experiments and obſervations, collected in the progreſs of electricity to its preſent advanced ſtate, that this kind of fuſion is attended with heat and ignition, as in the caſe of common fuſion. Phil. Tranſ. vol. li. part. i. art. 30 and 31.

FUSIVATA, in *Geography*, a town of Japan, in the iſland of Niphon; 56 miles S.S.E. of Meaco.

FUST, in *Architecture*, the ſhaft of a column; or that part comprehended between the baſe and the capital; called alſo the naked.

The word is French, and literally ſignifies a *caſk*.

The fuſt is that cylindrical part, which makes, as it were, the body or trunk of the column, excluſive of the head and foot.

FUSTIAN, in *Commerce*, a kind of cotton ſtuff, which ſeems, as it were, quilted, or whaled on one ſide.

Manege derives the word from *fuſtanum*, which in the corrupt Latin writers is uſed in the ſame ſenſe, and is ſuppoſed to be formed from *fuſtis*, on account of the tree whereon the cotton grows. Bochart derives it from *fuſtat*, which, in Arabic, ſignifies the ancient city of Memphis, where cotton is produced in great abundance. Right fuſtians ſhould be made altogether of cotton thread, both woof and warp.

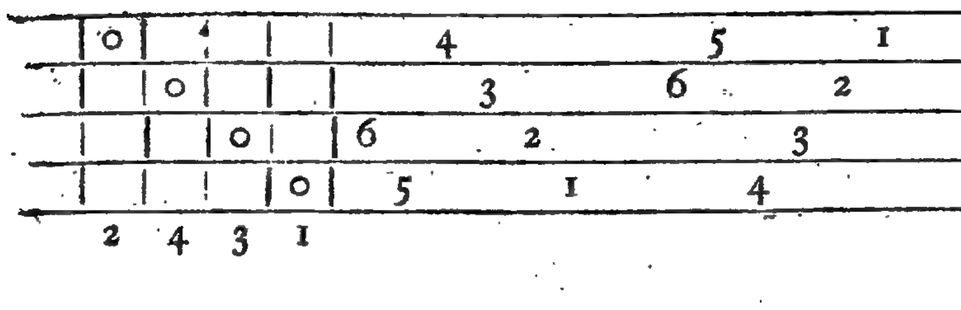
FUSTIAN, in the *Manufacture of Cloth*, is a ſpecies of coarſe thick twilled cotton, and is generally dyed of an olive, leaden, or other dark colour previouſly to its being uſed. Beſides the common fuſtian which is known by the name of pillow (probably pilaw) fuſtian, this manufacture, which is chiefly carried on in Lancaſhire, and the weſt riding of Yorkſhire, comprehends the cotton ſtuffs known by the names corduroy, velverett, velveteen, thickſett, and the other thick fabrics uſed for men's wearing apparel. The commoneſt kind of fuſtian is merely a twill of four, and ſometimes five leaves of a very cloſe ſtout fabric, and is very narrow, ſeldom exceeding 17 or 18 inches in breadth. It is cut from the loom in half pieces or ends as they are uſually called, and after undergoing the ſubſequent operations of dyeing, dreſſing, and folding is ready for the market. The end or half piece is generally from 30 to 40 yards.

The draught and cording of common fuſtian is very ſimple, being generally a regular or unbroken tweel of four or five leaves. Below are ſpecimens of a few different kinds ſelected from thoſe moſt general in Lancaſhire.

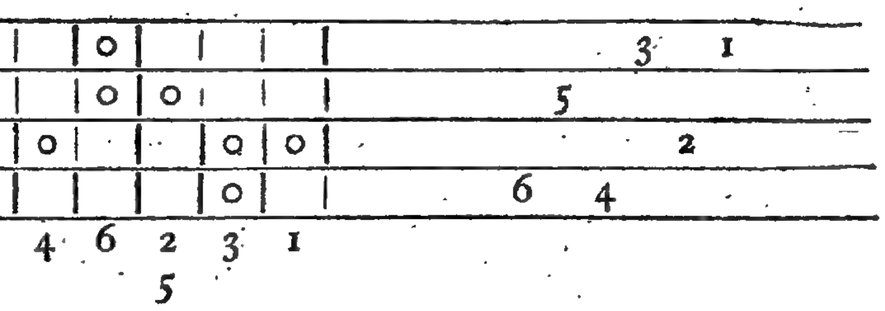
The number of leaves of heddles are directed by the lines acroſs the paper, and the cording by the cyphers at the left hand corners, thoſe which raiſe every leaf being diſtinguiſhed by the cyphers, and thoſe which ſink them left blank, as more eſpecially explained in the article DRAUGHT and *Cording*.

FUSTIAN.

No. 1.—Pillow Fuſtian.

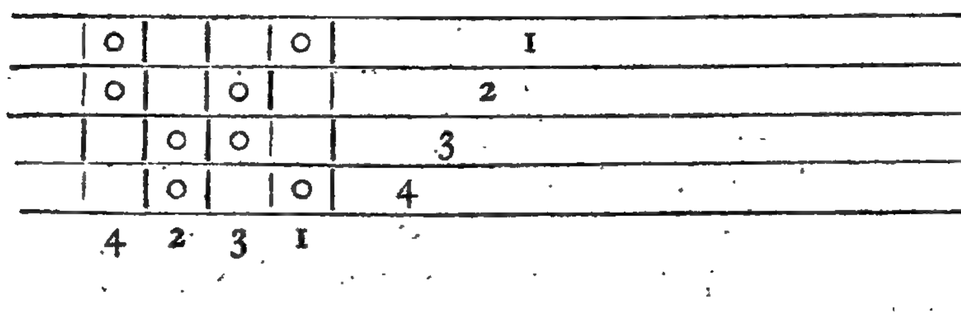


No. 2.—Plain Velveret.

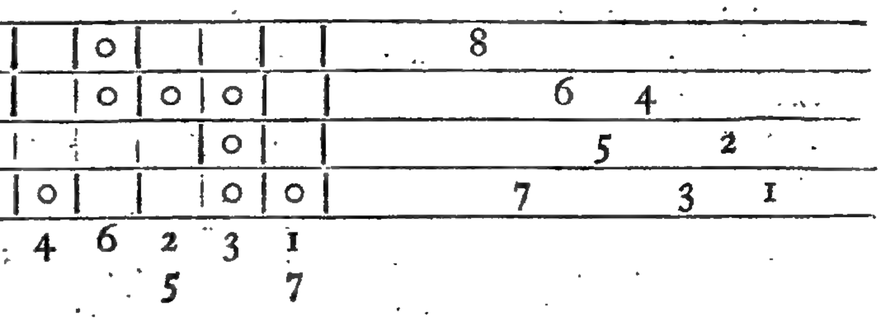


Of the above each contains four leaves of heddles or healds; that repreſented by No. 1. is wrought by four treddles, and that which is diſtinguiſhed by No. 2. by five; the ſucceſſion of inſerting the threads of warp into the heddles will be diſcovered by the figures between the lines, and the order in which the treddles are to be ſucceſſively preſſed down by the figures below.

No. 3.—Double Jean.

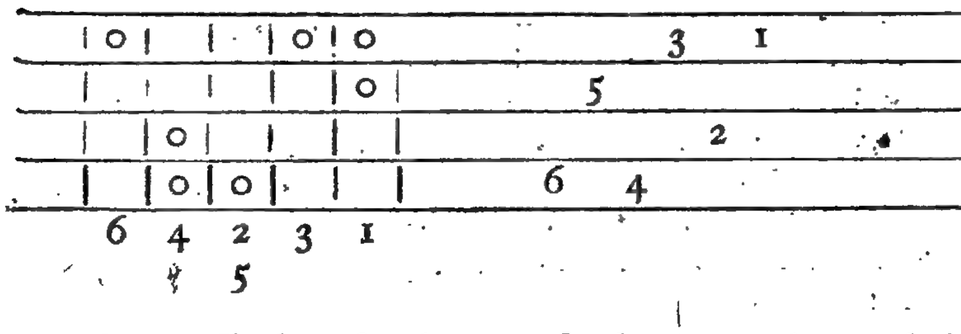


No. 4.—Plain Thickſett.

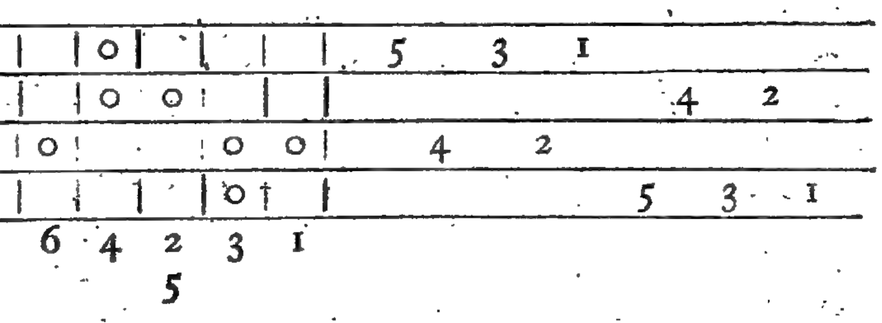


Theſe, like the former, are wrought with leaves. No. 3. requires four, and No. 4. five treddles. The ſucceſſion of inſerting the threads of warp, and of working the treddles, are marked by the reſpective numbers between and under the lines, as in the former example. Both are fabrics of cloth in very general uſe and eſtimation as low priced articles.

No. 5.—Beſt Thickſett.

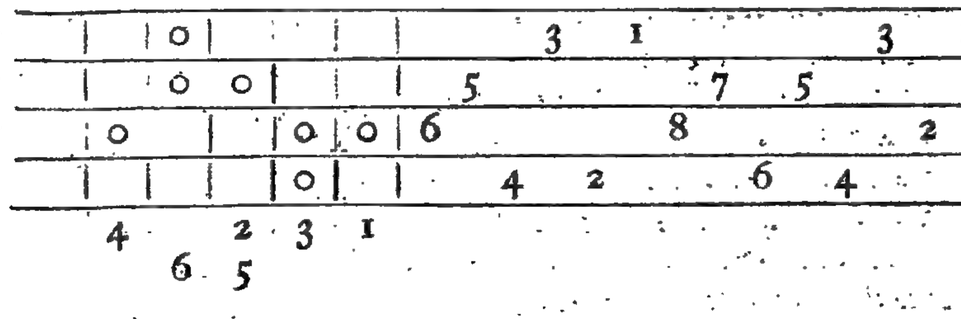


No. 6.—Velvet Tuft.

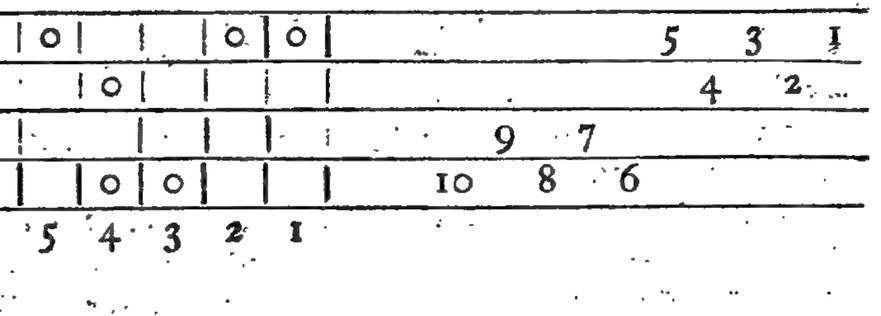


Theſe are further ſpecimens of what may be, and is, executed with four leaves, and in both examples five treddles are uſed. With two other ſpecimens we ſhall conclude our examples of this deſcription of work, and ſhall then add a very few ſpecimens of the more extenſive kinds.

No. 7.—Cord and Velveret.

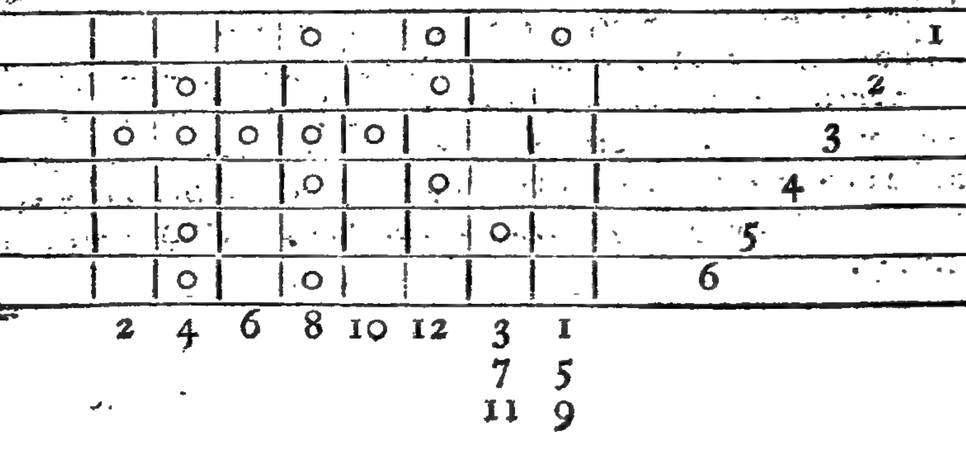


No. 8.—Thickſett Cord.

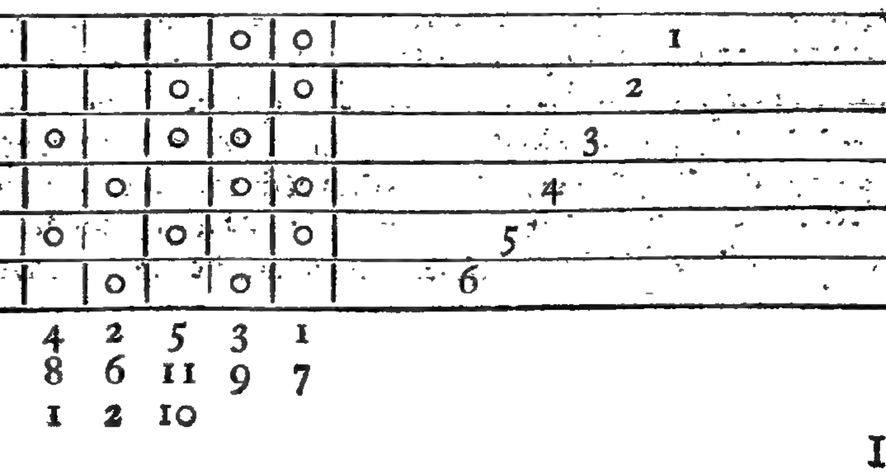


In theſe the ſucceſſion of drawing and working are marked like the former. The next are examples of patterns wrought with ſix leaves. No. 9. has eight, and No. 10. five heddles.

No. 9.—Double Corduroy.



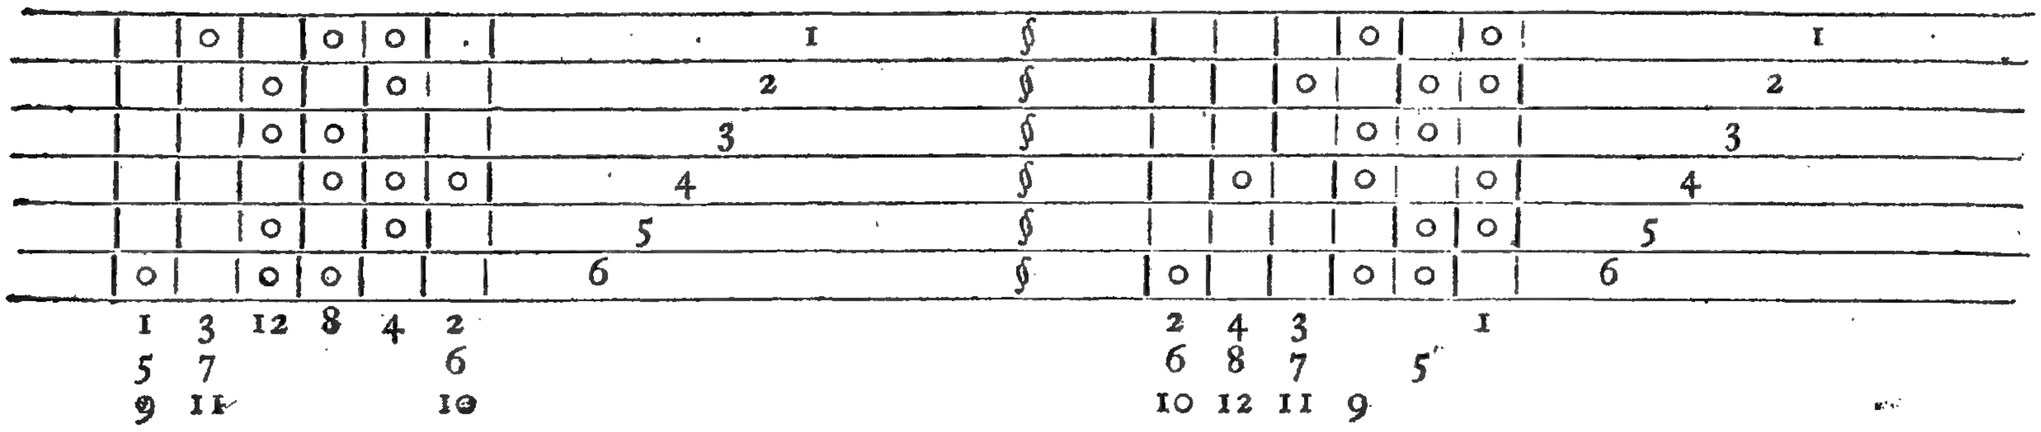
No. 10.—Genoa Thickſet.



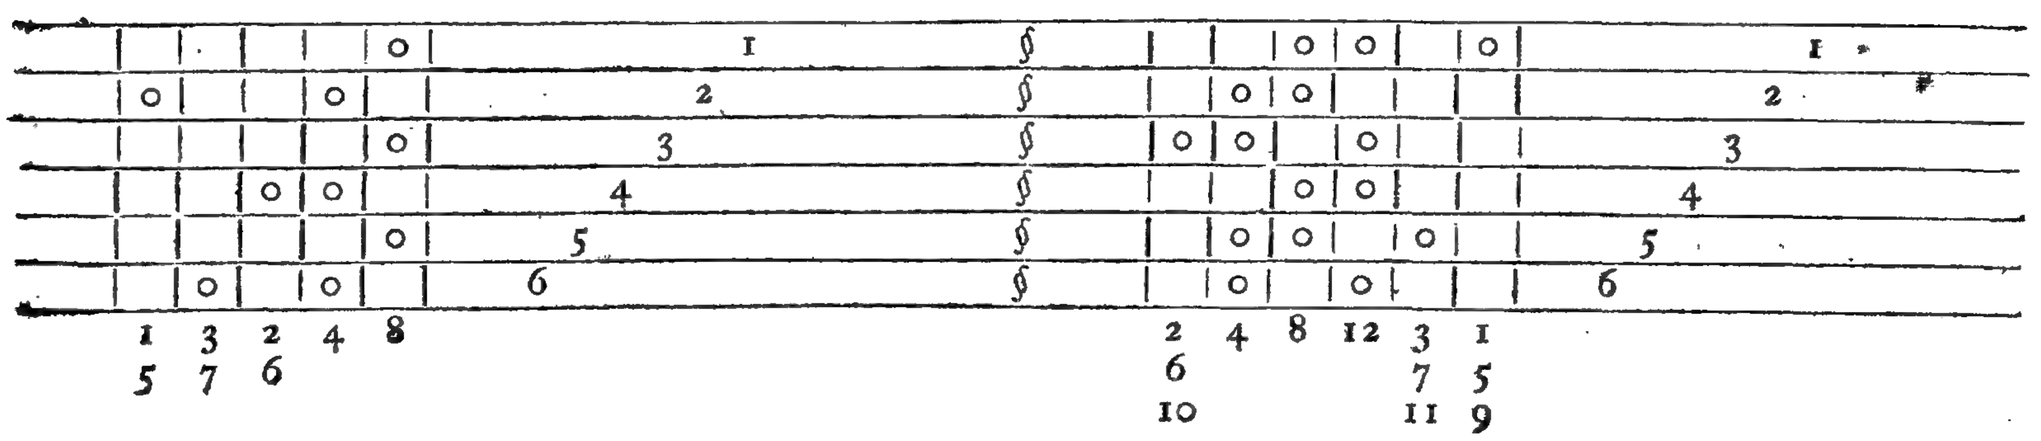
In

In both theſe the warp is inſerted into the heddles the ſame way. The difference is entirely in the application of the cords and in the ſucceſſion of preſſing down the treddles. We now give four ſpecimens of the ſpecies of fluſhed and cut work, known by the name of velveteen. They are alſo upon ſix leaves, and the difference is ſolely in the cording and in the treading.

No. 11. Queen's Velveteens. No. 12.



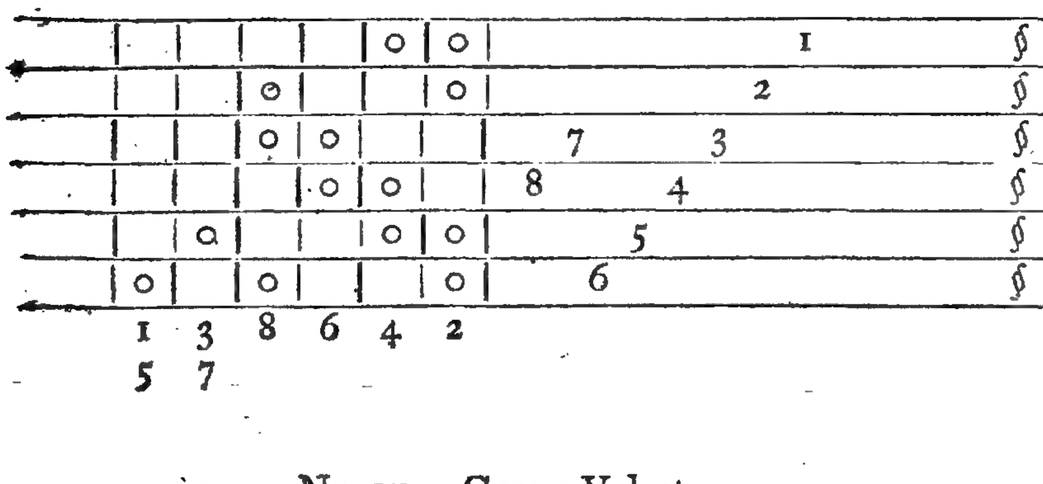
No. 13.—Plain Velveteen.



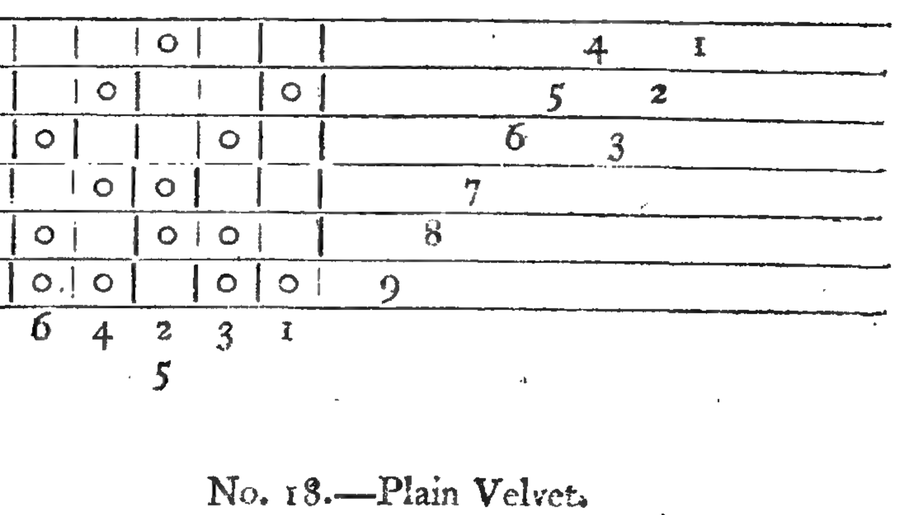
No. 14.—Genoa Velveteen.

The additional varieties of figure which might be given are almoſt endleſs, but the limits of this article will not admit a further detail. Thoſe already given are the articles in moſt general uſe. The varieties of fancy may be indulged to great extent, but it is univerſally found, that the moſt ſimple patterns in every department of ornamental weaving, are thoſe which attract attention and command purchaſers. We ſhall therefore only add two examples of king's cord or corduroy, two of Genoa and common velvet, and two more of jean. Theſe will be found below.

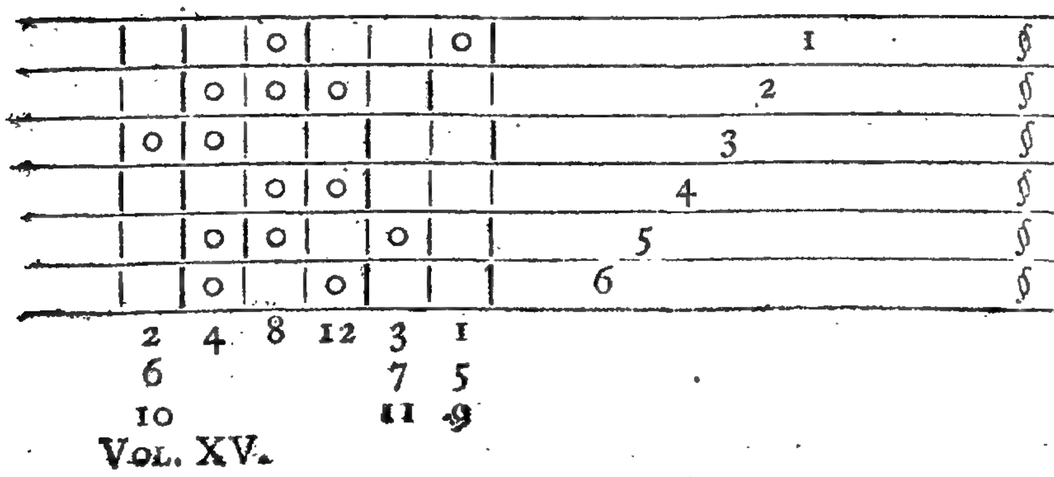
No. 15.—King's Cord.



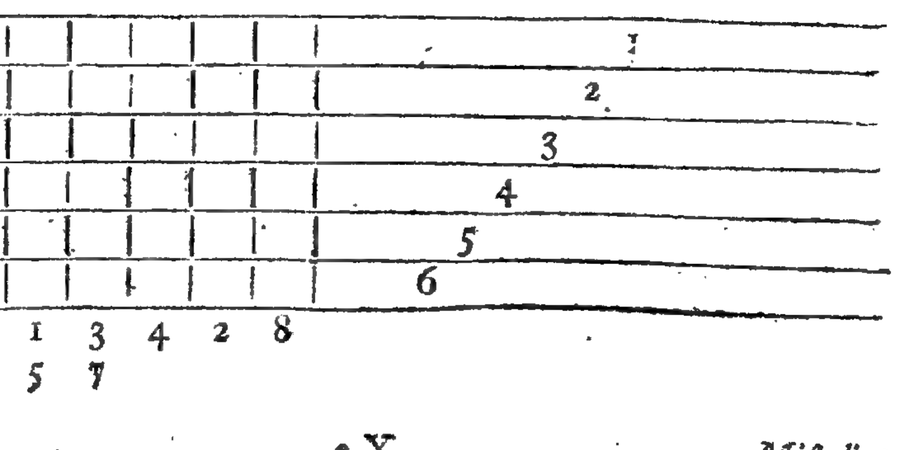
No. 16.—Dutch Cord.



No. 17.—Genoa Velvet.



No. 18.—Plain Velvet.



Miſcellaneous Remarks.—In the manufacture of cloth it is difficult to fix upon any generic term for a variety of articles which, however, bear a very near analogy to each other, and are only diſtinguiſhable either by a difference in the material of which they conſiſt, or ſome ſmall variation in the proceſs of manufacture. In this article the word fuſtian has been uſed as the generic term, and examples have been given of the moſt common fabrics of the fanciful varieties of this article. Dr. Johnſon contents himſelf with deſcribing fuſtian merely as a kind of cotton cloth, which although probably very juſt, conveys no impreſſion whatever to the mind, excepting, that in its raw ſtate it is a vegetable ſubſtance, found in moſt of the tropical climates, and that when manufactured it ſerves as a covering for the human body, or for ſome other domeſtic purpoſe.

The examples, ſhort as the article is, will be found to contain an abſtract of moſt of the articles known by the various names of fuſtian, jean, corduroy, thickſet, velveret, velveteen, &c. in the cotton manufacture: of plaiding, blanketing, kerſeymere, plum ſerge, &c. in the woollen, and of ſatin, &c. in the ſilk. Of velvet there are properly only two kinds, that with a plain and that with a tweeled, or, as it is here called, a Genoa ground or back. When the material is ſilk, it is called velvet, when cotton, velveteen, and this is the ſole difference. In the ſame way a common tweeled cloth, when compoſed of ſilk, is called ſatin, when of cotton, fuſtian or jean, of woollen, plaiding, ſerge or kerſeymere, and in the linen is diſtinguiſhed by a variety of names according to the quality or fineneſs, or the place where the article is manufactured. It would tend greatly to ſimplify an analyſis of the various manufactures of cloth, were a general nomenclature introduced, as has been ſo ſucceſsfully done, in the more comprehenſive and important ſcience of chemiſtry, and the univerſal uſefulneſs of the art, as embracing a variety of articles of neceſſity to the poor, and of ornamental luxury to the rich, would render the attempt very deſireable in every reſpect. But while the knowledge of the art continues to be confined to operative mechanics and to manufacturers, little diſpoſed to ſtudy ſimplicity or arrange and claſſify ideas, this is rather to be wiſhed for than expected. In all the fanciful branches which form the ſubject of this article, the cloth undergoes a variety of proceſſes after coming out of the weaver's hands. Of theſe, the firſt is cutting the fluſhed warp to raiſe the pile as it is called. This is performed on a flat table with a ſharp pointed knife. It is neceſſary in this to be careful that the knife may only cut the pile without injuring the back or fabric. I am not aware (ſays the writer of this article) that any attempt has ever been made to render this either more ſafe or ſpeedy by the aid of any kind of machinery. It is ſaid, indeed, that in the manufacture of Wilton carpets and hearth rugs, (which are merely worſted velvets,) grooved wires are introduced and cut out in the loom by the weaver, the groove in the wire ſerving as a guide for the knife, to prevent it from injuring the fabric of the cloth. The next operation is that of dyeing, which depending entirely on the chemical proceſſes neceſſary to give the greateſt poſſible brilliancy and durability of colour, to the material of which the cloth is compoſed, forms no part of this article. With little variation in the mechanical part, many kinds of cloth, differing widely in the material and equally ſo in the texture, are made: but the variety is boundleſs.

FUSTIAN, in *Criticiſm*, a word uſed to expreſs bombaſt. See BOMBAST and FRIGID.

FUSTIC, OLD, as it is called in this country, (the *bois jaune* of the French,) is the wood of a large tree, the MORUS *tinctoria*, which grows abundantly in many parts of the Weſt Indies and the American continent. It is of a ſulphur colour, pregnant with colouring matter, which is much more durable than any of the other yellow dyes, ſo that when applied without a mordant, the dye is conſiderably durable, but ſtill more ſo when uſed with the ſame mordants, as weld or quercitron. The decoction of fuſtic in water, when ſtrong, has a deep and ſomewhat dull red yellow, and by dilution becomes orange-yellow. Acids produce in it only a ſlight precipitate, which alkalies rediſſolve, rendering the liquor red. Fuſtic, though valuable on account of the durability of its colour, is ſeldom uſed for the pure yellows, as the colour given by it is dull and muddy. It is chiefly uſed in compound colours, as in forming green with a Saxon-blue baſis; or in producing, with a mixed mordant of alum and iron-liquor, an infinite variety of drab and olive dyes, in which caſe the dullneſs of its colour is of no conſequence. It is chiefly uſed in general dyeing, and ſeldom in printing. It goes much farther than weld.

Young fuſtic, the *fuſtet* of the French dyers, *Rhus cotinus*, or Venice ſumach, is a ſhrub growing in Italy, and the ſouth of France, which gives a fine greeniſh yellow without any permanence, ſo that it is never uſed alone, but merely as an acceſſory colour to heighten cochineal and other dyes, and occaſion their approach to yellow.

FUSTICK WOOD. See MORUS *tinctoria*.

FUSTIGATION, in the *Roman Cuſtoms*, a puniſhment inflicted by beating with a cudgel. This puniſhment was peculiar to freemen; for the ſlaves were ſcourged or laſhed with whips.

FUSTIGATION, *Fuſtigatio*, is alſo a penance enjoined by the Roman inquiſition.

FUSTUARIUM, in *Antiquity*, a Roman puniſhment, the ſame with fuſtigation.

FUSTUC, in *Botany*, a name given by ſome of the old writers to the tree which produces the piſtachia-nuts. The word ſounds ſo like the name of a wood uſed in dyeing, and called at this time *fuſtick*, that it might be ſuppoſed to expreſs ſome tree of the ſame kind; but it is of a very different origin. The Jews and Arabians have called the piſtachia-tree fiſtic and fuſtack, and from thence ſome have written the name fuſtuck or fuſtuc, the Greeks have written it φιστακ, and the barbarous Latin writers *fiſticio*, which ſounds very like the name piſtachio.

FUTAK, in *Geography*, a town of Hungary, on the Danube, oppoſite to Peter-Wardin, ſituated in a plain, 16 miles S.S.E. of Bacs.

FUT-FA, in *Muſic*. See F and CLEF.

FUTTAGUNGE, in *Geography*, a town of Hindooſtan, in Oude; 15 miles S.E. of Fyzabad.

FUTTASING, a circar of Bengal, bounded on the N.E. and E. by Raujeſhy and Kiſhenagur, on the S. by Burdwen, and on the N.W. by Raujeſhy and Birboom; of a triangular form, and about 60 miles in circumference.

FUTTEHPOOR, a town, or rather village, of Hindooſtan, 23 miles from Agra. It is encloſed with a high ſtone wall, of great extent, built by the emperor Akber or Acbar. The ſpace within does not appear to have ever been nearly filled with buildings, and the part now inhabited is but an inconſiderable village. This ſpace is divided by a hilly ridge of conſiderable elevation, which runs nearly from S.W. by W. to N.E. by E., and extends beyond the incloſure, four or five miles on each ſide. Near the centre of the incloſure, on the moſt elevated part of the rock, is built the tomb of Shah Selim Chuſtee, by the efficacy of whoſe devotion, the empreſs of Akber, after remaining for ſeveral years barren, became pregnant, and bare a ſon, named Selim in honour of the ſaint. The approach to this mauſoleum is magnificent,

magnificent, and impreſſes the mind of a ſpectator with ſenſations of ſublimity. On the ſame ridge is an ancient palace of Akber. Mr. Hunter, in his return from Oujein to Agra, viſited this place, and has particularly deſcribed it. Aſiatic Reſearches, vol. vi. p. 75, 8vo.

FUTTIAPOUR, a town of Hindooſtan, in Bahar; 24 miles S.S.W. of Patna.

FUTTIGUR, a town of Hindooſtan, in Oude; 5 miles S. of Furruckabad.

FUTTIPOUR, a town of Hindooſtan, in Oude; 30 miles S.E. of Corah.—Alſo, a town in Bahar; 40 miles N.N.W. of Durbungah.—Alſo, a town of Bahar; 13 miles S.S.E. of Durbungah.—Alſo, a town of Bahar; 18 miles N.E. of Coprah. N. lat. 26 3'. E. long. 83° 8.—Alſo, a town of Allahabad; 27 miles N.W. of Currah. N. lat. 25° 58'. E. long. 81° 13.—Alſo, a town of Bengal; 12 miles N. of Nangora.—Alſo, a town of Bengal; 56 miles N.E. of Purneah.

FUTTOCKS, in a *Ship*, the timbers raiſed over the keel, or the compaſſing timbers which make her breadth.

Thoſe next to the keel are called ground-futtocks, and the reſt upper-futtocks.

Futtock *Shrouds*. See Shrouds.

FUTURE, ſomething to come hereafter.

We ſay a future ſtate, a future contingency; there is none but God to whom future things are preſent.

Future, or Future *Tenſe*, in *Grammar*, denotes an inflexion of verbs, whereby they denote, that a thing will be in ſome time yet to come. As, the laſt day will come; I ſhall ſee an end.

The future time admits of two caſes; either we may intend to expreſs a thing that ſhall come to paſs in a ſhort time; or a thing that ſhall happen in any indefinite time. Thus the Greeks have their *paulo poſt futurum*, μετ' ολιγον μελλων, which marks a thing juſt going to be done; as ποιησομαι; beſide the common indefinite future, ποιησω, *I will do it; ſcribam, I ſhall write.*

In Latin, Italian, French, and even in Engliſh, the future of the indicative expreſſes only the deſign or intention of doing a thing, or ſimply that the thing will be; as, I will praiſe, I will be approved: and the future of the ſubjunctive ſhews, that the thing will be done under certain circumſtances; when I ſhall have ſeen Verſailles, I will tell you. Sometimes the future is expreſſed in Engliſh by the preſent; if I meet your friend, I will ſend him to you; *ſi offendero, ſi incidero*, &c.

Mr. Harris, in his diſtribution of tenſes, reckons three definite future tenſes, beſides the common indefinite future, which he calls the aoriſt of the future, *viz.* the inceptive future, as *ſcripturus ero, I ſhall be beginning to write;* the middle or extended future, as *ſcribens ero, I ſhall be writing;* and the completive future, as *ſcripſero, I ſhall have done writing.* See Tense.

FUTWA, in *Geography*, a town of Hindooſtan, in Bahar, at the union of the Little Pompon with the Ganges; 7 miles S.E. of Patna. N. lat. 25 30'. E. long. 55 28'.

FUUR Land, an iſland of Denmark, in Lymfiord gulf; about 12 miles in circumference, of an irregular triangular form. It contains a town, called "Fuur," and two or three villages. N. lat. 56 50'. E. long. 9° 2'.

FUZE, Fuzee, or *Fuſee*, in the *Ordnance Department*, relates to the device in common uſe of ſupplying a bomb-ſhell, or grenade, with fire, ſo that, on arriving at its deſtination, the gunpowder contained within the cavity of the ſhell may be ignited, and cauſe that dreadful exploſion, which in the aggregate is uſually termed a "bombardment." To effect this purpoſe, a piece of tough wood is bored through for its whole length, and then exteriorly turned to ſuch a diameter as may cauſe it, when driven nearly up to the neck, to ſtop the fuſe-hole, made in every ſhell for the reception of the fuſe, perfectly tight. This requires that the form of the fuſe ſhould be rather conical, and that the thicker end ſhould be farther reinforced by ſuch a ſwell, as ſhould allow its interior to be hollowed out into the form of a cup; whereby a larger ſurface is expoſed to the blaze occaſioned by the diſcharge of the powder by which the ſhell receives its impulſe from the mortar, howitzer, in which it was placed.

It being neceſſary that fuzes ſhould not burn more than two or three ſeconds beyond that time for which their flight is calculated, great nicety is requiſite in the preparation of the materials uſed in their compoſition, which are generally according to the following proportions.

Nitre	3 lbs.	4 oz.	or	13 parts.
Sulphur	1 lb.		—	4 parts.
Mealed powder	2 lbs.	12 oz.	—	11 parts.

Theſe being ſeverally pulverized with the greateſt care, and ſifted into a receiver, wherein they are mixed as they fall in, are blended perfectly, ſo that every part of the maſs may be ſimilarly compoſed. A ſmall quantity is then poured into the woodeu tube, which is placed in a very ſtrong claſp-pillar made of braſs, and ſecured by ſliding rings, ſo as to prevent the wood from ſplitting when the man who has to "drive the compoſition," ſtrikes the metal rod with much force; thereby occaſioning the compoſition to occupy very little ſpace, and to become extremely hard. In this manner, little by little, the tube is filled. It requires, however, great experience and judgment to fill every part of the tube with equal compactneſs, and to make any number of fuzes all of equal hardneſs, in order that their duration may correſpond exactly according to their reſpective lengths. It is evident that ſuch compoſition as is looſely rammed will burn out rapidly, while ſuch as is rammed too hard, will burn ſo very ſlowly as to give time for the eſcape of thoſe near whom a ſhell may fall; or even for their knocking the fuze out altogether.

The following table will ſhew the ſeveral proportions of fuzes, and their appropriate ſizes to various claſſes of mortars, &c.; it will be ſeen that a well-made fuze ſhould burn at the rate of one quarter of an inch for every ſecond of time.

Nature of the mortar, &c.	Diameter of the fuze.			Compoſition.			Number of fuzes drove by one man in a day.
	Below the cup.	At the bottom.	At the cup.	Diameter.	Length.	Time it burns.	
Inches.	Inches.	Inches.	Inches	Inches.	Inches.	Seconds.	Number.
13	2.1	1.575	2.49	.5	8.4	35	25
10	1.8	1.35	2.13	.438	7.2	33	25
8	1.3	1.25	1.78	.375	6.37	29	30
5½	1.1	.825	1.3	.275	4.4	18	50
4⅕	1.0	.75	1.18	.25	3.5	15	700
Grenade	0 8	.6	.9	.2	2.25		1000

The diameter within the cup ſhould be equal to three diameters of the bore; the depth of the cup ſhould be 1½ diameter of the bore; and the thickneſs of wood at the bottom of the bore ſhould be equal to two diameters. Fuzes ſhould be painted over entirely to preſerve the compoſition;

and, when intended for field ſervice, ſhould be marked by narrow black lines, into ſeconds and half ſeconds, ſo as to be promptly cut to any duration of flight.

FUZEE, in the *Manege*, two dangerous ſplents, joining from above downwards: commonly a fuzee riſes to the knee and lames the horſe.

Fuzees differ from ſcrews or thorough ſplents in this, that the latter are placed on the two oppoſite ſides of the leg. See SPLENT.

FUZILEERS. See FUSILIERS.

FUZIR, in *Geography*, a town of Hungary; 12 miles S.S.E. of Caſchau.

FUZZEN, in *Rural Economy*, a provincial term ſometimes employed to ſignify the natural juice or nouriſhment of a ſubſtance, or the ſtrength of it. It is occaſionally written *fuzen*.

FYEL. See FAYAL.

FYEN. See FUNEN.

FYERS. See FOYERS.

FYGAREERA, a town of Hindooſtan, in the circar of Aurungabad; 10 miles S. of Jaſſierabad.

FYKI, a town of Japan, in the iſland of Niphon; 40 miles N.E. of Jedo.

FYNIAL, the finiſhing ornament of a pediment or canopy, or of a pinnacle, in the pointed order of *Architecture*. The term is now generally confined to the carved trefoil, or other ornament at the top of thoſe members; but in the will of Henry VI. in which he provides for the building of his chapel at Cambridge, it is taken for the whole crocketted pinnacle which was ſet upon each buttreſs.

FYOT, DE LA MARCHE, CLAUDE, in *Biography*, count de Bosjan, a French eccleſiaſtic, was born at Dijon in the year 1630. He was educated among the Jeſuits, and on occaſion of one of their public days, Fyot was honoured by having Lewis XIV. among the number of his auditors, who was ſo much pleaſed with the performance, that in the year 1662 he nominated him abbot of the collegiate church of St. Stephen, at Dijon. The monarch alſo created him his almoner, and prior of Notre Dame, at Portarlier, on the Saone. He roſe to ſtill higher honours in the church and ſtate, and, at length, in 1668, the king gave him the rank of honorary counſellor of the parliament of Dijon; and, in the following year, a brevet of counſellor of ſtate. He died at Dijon in 1721, at the great age of ninety-one. He eſtabliſhed and endowed a ſeminary for the education of young eccleſiaſtics, and was himſelf a munificent benefactor to it. He publiſhed, in 1696, "A Hiſtory of the Abbey of St. Stephen," which is held in high eſtimation on account of the profound and curious reſearches which it contains relating to the antiquities of the city of Dijon. Beſides this he was author of ſeveral pious and devotional treatiſes. Moreri.

FYTHA-EL-BOTHNA, in *Geography*, a town of Africa, in the country of Sahara; ſo called, as Dr. Shaw ſuppoſes, from the number of turpentine trees which grow there; 34 miles S.W. of Booſerjoone.

FYTT, JOHN, in *Biography*, an eminent painter of animals, fruit, and flowers, born at Antwerp in 1625. He was an artiſt of very uncommon powers; who, having paid the cloſeſt attention to the productions of nature, imitated them with great ſpirit, truth, and accuracy. His colour is very rich and agreeable, his touch firm and animated; he generally worked with a full body of colour, and great readineſs and freedom of hand is exhibited in his works, which render them eaſily cognizable.

His choice of ſubjects was among the brute and the vegetable creation, whoſe character he rendered with great fidelity; deſcribing ſometimes in his more laborious works the hairs and plumage of his beaſts and birds. He frequently painted pictures conjointly with Rubens and Jordaens, and completely unites with their extraordinary effects his own peculiar labours.

FYVIE, in *Geography*, a town of Scotland, in the county of Aberdeen, near the Ythan, in the road from Aberdeen to Bamff; 25 miles N. of Aberdeen.

FYZABAD, a town of Hindooſtan, and till of late the capital of Oude, ſeated on the river Gogra, a very large river from Thibet, and about eighty miles E. of Lucknow, and 360 from Calcutta. It is a very large city, and though for many years the capital of the nabobs of Oude, inconveniently ſituated, even before the Rohilla conqueſt. Nearly adjoining to it is the very ancient city of Oude or Ajudiah. This place was founded by Sadatkhan, a Perſian, who was 40 years governor of the province. He firſt built a palace, to which he annexed extenſive gardens, and made this the place of his reſidence; he then added many houſes, till it became a large city, and the capital of the province; it was defended with a fortreſs, a ditch, tower, ramparts, &c. N. lat. 26° 45'. E. long. 82° 24'.

G.

G, The ſeventh letter of our alphabet, and the fifth conſonant; though in the alphabets of all the oriental languages, the Hebrew, Phœnician, Chaldee, Syriac, Samaritan, Arabic, and even Greek, G is the third letter.

The Hebrews call it *ghimel*, or *gimel*, q. d. *camel*; becauſe it reſembles in its form the neck of that animal; and the ſame appellation it bears in the Samaritan, Phœnician, and Chaldee: in the Syriac it is called *gomel*, in Arabic *gim*, and in Greek *gamma*.

The letter G is of the mute kind, and cannot be any way ſounded without the help of a vowel. It is formed by the reflection of the air againſt the palate, made by the tongue, as the air paſſes out of the throat; which Martianus Capella expreſſes thus, G ſpiritus cum palato; ſo that the G is a palatal letter.

G in Engliſh has two ſounds, one from the Greek Γ, and the Latin, which is called that of the hard G, becauſe it is formed by a preſſure, ſomewhat hard, of the fore-part of the tongue againſt the upper gum; which ſound it retains before *a*, *o*, *u*, *l*, *r*; as *gate*, *go*, *gull*. At the end of a word it is always hard, as *ring*, *ſing*, &c. The other ſound, called that of the ſoft G, reſembles that of *j*, and is commonly, though not always, found before *e* and *i*, as in *gem* and *gibbet*. To this rule, however, there are many exceptions; G is often hard before *i*, as *give*, &c. and ſometimes before *e*, as *get*, &c. It is alſo hard in derivatives from words ending in *g*, as *ſinging*, *ſtronger*, &c. and generally before *er*, at the end of words, as *finger*. G is mute before *n*, as *gnaſh*, *ſign*. *Gh* has the ſound of the hard G in the beginning of a word, as *ghoſtly*; in the middle, and ſometimes at the end, it is quite ſilent, as *right*, *though*. At the end of a word *Gh* has often the ſound of *f*, as *laugh*. Johnſon.

The Latins took the liberty to drop the letter G at the beginning of words, before an *n*; as in *gnatus*, *gnoſco*, *gnobilis*, *gnarrat*, &c. which they ordinarily wrote *natus*, *noſco*, *nobilis*, &c. They alſo frequently changed it into *c*; as *gamelus*, into *camelus*; *gragulus*, *graculus*; *quingentum*, *quincentum*, &c. Sometimes it was put inſtead of *n*, before a *c*, and for another *c*; as *Agchiſes*, *aggora*, *agguilla*, &c. for *Anchiſes*, *ancora*, *anguilla*, &c. And inſtead of *p*; as *magalia*, for *mapalia*, &c. G is alſo uſed inſtead of *q*, and *q* inſtead of G, as in *anquina*, *angina*, *anguina*, &c. inſtead of *r*, as in *aquagium*, for *aquarium*; *agger*, for *arger*, &c. And inſtead of *s*, as in *ſpargo*, *ſparſi*, *ſparſum*; or rather it is retrenched from thoſe laſt words to avoid the cacophony of *ſpargſi*, or *ſparcſi*. G is alſo put for *c*; as in *Cneius*, for *Gneius*; *Caius*, for *Gaius*; *Gaeta*, for *Caieta*; and for *v*; as in *figere*, for *fivere*. See N, P, &c.

The northern people frequently change the G into *v*, or *w*; as in *Gallus*, *Wallus*; *Gallia*, *Wallia*, *Vallia*, &c. For in this inſtance it muſt not be ſaid that the French have changed the *w* into G; becauſe they wrote *Gallus* long before *Wallus*, or *Wallia*, were known; as appears from all the ancient Roman and Greek writers.

And yet it is equally true, that the French change the *w* of the northern nations, and *v* conſonant, into G; as *Williel-mus*, *William*, into *Guillaume*; *Wulphilas*, into *Gulphilas*; *Vaſco*, into *Gaſcon*, &c.

Diomed, lib. ii. cap. de Litera, calls G a new letter; his reaſon is, that the Romans had not introduced it before the firſt Punic war; as appears from the roſtral column, erected by C. Duilius, on which we every where find a *c* in lieu of G. It was Sp. Carvilius who firſt diſtinguiſhed between thoſe two letters, and invented the figure of the G; as we are aſſured by Terentius Scaurus. The *c* ſerved very well for G; it being the third letter of the Latin alphabet, as the G or γ was of the Greek.

The G is found inſtead of *c* on ſeveral medals: Vaillant, Num. Imperat. tom. i. p. 39. M. Beger produces a medal of the Familia Ogulnia, where GAR is read inſtead of CAR, which is on thoſe of M. Patin. But the *c* is more frequently ſeen on medals in lieu of G; as AUCUSTALIS, CALLAECIA, CARTACINENSIS, &c. for AUGUSTALIS, &c. Not that the pronunciation of thoſe words was altered, but only that the G was unartfully or negligently cut by the workmen; as is the caſe in divers inſcriptions of the Eaſtern empire; where AUC, AUCC, AUCCC, are frequently found for AUG, &c.

The form of our G is taken from that of the Latins, who borrowed it from the Greeks; the Latin G being certainly a corruption of the Greek gamma, Γ, as might eaſily be ſhewn, had our printers all the characters and forms of this letter which we meet with in the Greek and Latin MSS. through which the letter paſſed from Γ to G.

As to the gamma of the Greeks, it is manifeſtly the ג of the Hebrews or Samaritans. All the difference between the gamma and ghimel conſiſts in this, that the one is turned to the right, and the other to the left, according to the different manners of writing and reading, which obtained among thoſe different nations; ſo that all the pains Salmaſius has taken on Solinus, to prove that the G was derived from the Greek kappa, is loſt.

G, as a Roman abbreviature, has various ſignifications. It denotes *gratis*, *gens*, *gaudium*, &c. G. V. ſignifies *genio urbis*, and G. P. R. *gloria populi Romani*.

G has alſo been uſed as a numeral letter, ſignifying 400, according to the verſe,

"G quadringentos demonſtrativa tenebit."

When a daſh was added at the top, $\overline{G}$, it ſignified forty thouſand.

G, in *Chronology*, is the ſeventh dominical letter.

G, on the French *Coins*, denotes the city of Poitiers.

G, in *Muſic*, is the loweſt ſound of the ſcale of Guido, in which it is called *Gammut*; which ſee. The octave above

gammut, in the ſame ſcale, is called *ut*, or G *ſol-re-ut*. It is called *ut*, or *do*, as the firſt note of the *durum hexachord*. (See HEXACHORD.) It is called *ſol*, as 5th of the natural hexachord of C; and *re*, as the 2d of the molle hexachord of F. G gives a name to the clef in which almoſt all treble parts are written for inſtruments; as the violin, flute, clarinet, and hautbois: it is called by the Italians *chiave di violino*, and is placed on the ſecond line thus:

During the 17th century, and part of the laſt, the French placed this clef on the firſt line, and uſed no other treble clef; whence it was called the French clef. Geminiani, in his firſt book of ſolos, has uſed it, to ſave leger lines, in very high paſſages.

The key of G, with a minor or flat third, is called by the Italians G molle.

GA-BOAT, in *Engineery*, is the name of a ſort of veſſels which navigate the Clyde river.

GAANA, in *Ancient Geography*, a town of Aſia, in Coeleſyria. Ptolemy.

GAARDE, in *Geography*, a town of Norway, in the dioceſe of Aggerhuus; 56 miles N.W. of Chriſtiania.

GABA, in *Ancient Geography*, a town of Paleſtine, in the tribe of Benjamin. Joſh. xviii. 24.—Alſo, a town of Judea, in the tribe of Zabulon; ſituated, according to Joſephus, at the foot of mount Carmel, between Ptolemais and Cæſarea.

GABADANIA, a country of Aſia, in Cappadocia, ſituated at the foot of mount Taurus, and adapted merely to paſture.

GABAE, a country of Aſia, ſituated between the Maſſagetæ and Sogdiana. Arrian.

GABALA, a town of Phœnicia, ſituated 18 miles from Laodicea, on the ſea-coaſt, at the foot of mount Caſius.—Alſo, an epiſcopal town of Aſia, in Lydia.

GABALA, in *Geography*, a town of Arabia Felix; 64 miles N.N.E. of Aden.

GABALÆCA, in *Ancient Geography*, a town of Hiſpania Tarragonenſis, at ſome diſtance from the ſea, in the country of the Varduli. Ptolemy.

GABALE, a Mediterranean town of Media. Ptol.

GABALE, in *Mythology*, a deity worſhipped at Heliopolis, under the figure of a lion, with a radiant head; and it is thus repreſented on many medals of Caracallus.

GABALI, or GABALLI, in *Ancient Geography*, a people of Gaul, who belonged to Aquitania Prima.

GABARA, one of the three principal towns of Galilee; the other two were Sephoris and Tiberias.

GABARDINE, from the Italian *gavardina*, has been ſometimes uſed to denote a coarſe frock, or mean dreſs. In this ſenſe it is uſed by Shakſpeare in his Tempeſt and Merchant of Venice, and by Butler in his Hudibras, book i.

GABARON, in *Geography*, a bay on the S.W. of Louiſburg, on the iſland of cape Breton.

GABARRET, a town of France, in the department of the Landes, and chief place of a canton, in the diſtrict of Mont-de-Marſan, ſeated on the Geliſe; 24 miles E. of Mont-de-Marſan. The place contains 605, and the canton 7882 inhabitants, on a territory of 480 kiliometres, in 19 communes.

GABASALKI, a town of Ruſſia, in the government of Viborg, or Wiburgh; 36 miles N. of Serdopol.

GABBARA, a name which the Egyptians gave the dead bodies which they kept by them, inſtead of burying them.

That people, out of a cuſtom which they had received from their anceſtors, and which aroſe, in ſome meaſure, from the poſition of their country, which is expoſed to the inundations of the Nile, uſed to wrap up the bodies of perſons of eminence, particularly thoſe of ſaints and martyrs, in a great number of linen cloths, with balms and ſpices; and inſtead of interring them, they preſerved them in their houſes: thinking that thereby they did them much more honour. (See EMBALMING, and MUMMY.) And theſe, St. Auguſtine tells us, were what they called gabbaras. Sermon cxx. de diverſis, cap. 12.

Pliny makes mention of the ſame thing, lib. vii. cap. 16. where he relates, that in the time of Claudius, a gabbara was brought from Arabia, almoſt ten feet long.

The word is Arabic, Syriac, and Hebrew, formed of גבר, *gaber*, *a man*, and denotes an embalmed body.

GABBIANI, ANTONIO DOMINICO, in *Biography*, a painter of hiſtory and portraits, born at Florence in 1652. He began his career under the tuition of Soutermans, and Vincenzio Dandini, and acquired all the freedom of execution and deſign, together with the weakneſs and defects of ſtyle which thoſe maſters exhibited in their works. He was highly patronized and encouraged by the grand duke Coſmo III., who ſent him to Rome, to ſtudy in the Florentine academy there, under the direction of Ciro Ferri. He excelled moſt in ſubjects of a light and agreeable nature; yet he had a large ſhare of more ſerious employment, and painted many altar-pieces. They are not in a ſtyle ſuited to their importance, when compared to the fine works of a better period. His moſt famed work is the cupola of Coſtello, which was never completed, as he fell from a ſcaffold, and was killed during the time he was working upon it in 1726.

GABBRONITE, in *Mineralogy*, a new mineral ſubſtance, firſt diſcovered in Norway, and deſcribed by profeſſor Schumacher of Copenhagen, who applied the above name to it, derived from its reſemblance in point of colour and fracture to ſome varieties of the ſerpentine rocks, called *gabbro* by the Italians.

Its colour is blueiſh or greeniſh-grey, rather tending to leek-green, and alſo greyiſh mountain green. It has been found maſſive and diſſeminated. Luſtre faintly glimmering, or dull; not greaſy to the touch. Fracture cloſe, even, or flat conchoidal, ſometimes ſplintery, in the manner of hornſtone. Fragments indeterminately angular, with pretty ſharp and ſtrongly tranſlucent edges.

It gives no ſparks with ſteel, and though it ſcratches glaſs, is likewiſe ſcratched by this latter, and by the knife. It is not eaſily frangible: when triturated it yields a white powder. Specific gravity 2.947.

Before the blow-pipe it immediately loſes its colour and becomes white: and farther urged by the heat of the flame, it fuſes without ebullition into a white opaque or faintly tranſlucent pearl. With borax it yields a clear but rather veſicular pearl.

The blueiſh-grey variety, which is found in the Kenlig mine at Arendal in Norway, is accompanied by black, maſſive, fine-grained, common hornblende, and reddiſh-grey ſcaly lime-ſtone. That of greyiſh mountain green colour occurs at Friedrickſvärn in Norway, diſſeminated in a rock compoſed of common hornblende, common and labrador feldſpath. It is alſo accompanied by ſpecular iron and talc.

This ſubſtance, not being analyſed, its nature is not yet exactly known. Some mineralogiſts ſuſpect it to be nearly allied to that kind of meagre nephrite, called *feldſpath tenace* by Haüy.

GABBULA, in *Ancient Geography*, a town of Aſia,

in Syria, ſituated N.E. of a Salt-lake, E. of Chalcis, and S.E. of Chalybon.

GABE, a town of Syria, called by Joſephus Gaba, and by Pliny Gabba. The latter of whom intimates that it was one of the tetrarchies, which adjoined to the towns of the Decapolis.—Alſo, a ſmall town of Paleſtine, 16 miles from Cæſarea; probably the ſame with the preceding.

GABEL, or GABELLE, in the *French Cuſtoms*, a duty or impoſition on ſalt.

Etymologiſts are divided as to the origin of the word. Some derive it from the Hebrew *gab*, a *preſent*; others from קבל, *to deliver*; others from קבלה, *kabbalah*, *receipt*; others from *ghauel*, or *gabe*, *unjuſt law*; and others from the corrupt Latin *gabella*, or *gablum*, *tribute*.

The gabel is let out to farm; and formed, before the revolution in France, the ſecond article in the king's revenue.

There were three farms of gabels: the firſt comprehended the greateſt part of the kingdom; the ſecond was that of the Lyonnois and Languedoc; and the third that of Dauphiné and Provence. There were ſeveral provinces exempt from the gabel, having purchaſed that privilege of Henry II.

This duty is ſaid to have had its riſe in France, in 1286, under Philip the Fair. Philip the Long took a double per livre on ſalt, by an edict in 1318, which he promiſed to remit when he was delivered from his enemies; which was renewed by Philip de Valois in 1345; and the duty was raiſed to four deniers per livre; king John reſumed it in 1355, and it was granted to the Dauphin in 1358, to ranſom king John. It was continued by Charles V. in 1366; after his deceaſe it was ſuppreſſed, but revived again by Charles VI. in 1381. Louis XI. raiſed it to twelve deniers per livre; and Francis I. in 1542, to twenty-four livres per muid; and it has been conſiderably augmented ſince that time; ſo that a minot of ſalt paid a duty of 52 livres, 8 ſols, and 6 den. Philip de Valois firſt eſtabliſhed granaries and officers to the gabelles, and prohibited any other perſons from ſelling ſalt; from which time the whole commerce of ſalt, for the inland conſumption, lay wholly in the king's hands, who ſold and diſtributed every grain thereof by his farmers, and officers created for the purpoſe.

The produce of this impoſt was ſo conſiderable, that it was computed to make one fourth of the whole revenue of the kingdom.

GABEL, or *Gable*, is alſo uſed, in ſome of our *Ancient Writers*, for any ſort of tax, or impoſition: as gabel of wines, of ſilks, &c.

GABEL, or *Gablona*, in *Geography*, a town of Bohemia, in the circle of Boleſlaw; 45 miles N. of Prague. N. lat. 50° 44′. E. long. 14° 54′.

GABELLUS, in *Ancient Geography*, *La Secchia*, a river which commenced on the confines of Apuani, in Liguria, and diſcharged itſelf into the Padus.

GABENA, a town of Aſia, in Media. Ptol.

GABERSTORF, in *Geography*, a town of Stiria; 10 miles W.S.W. of Gnaa.

GABIANA, in *Ancient Geography*, a province of Aſia, near Suſiana, which belonged to the Elymæans, according to Strabo.

GABIÆI, a town of Italy, in Latium; nearly E. of Rome.

GABIN, in *Geography*, a town of the duchy of Warſaw; 40 miles W. of Warſaw.

GABINDA, or KAPINDA, a town of Africa, in the kingdom of Loango.

GABINIA TOGA. See TOGA.

GABINIAN LAW, in *Roman Antiquity*, a law, ſo called from Gabinius, tribune of the people, who, at the inſtigation of Pompey, propoſed it for clearing the ſeas of the pirates, whoſe number and power were daily increaſing. Theſe robbers fitted out at firſt but a ſmall number of light veſſels; but upon their being protected by Mithridates, who, during his war with Rome, took them into his ſervice, they equipped 1000 gallies, and exerciſed a kind of ſovereignty over all the coaſts of the Mediterranean. They ſpared not one temple that was famous for its riches on the coaſts of Italy, Greece, and Aſia. All the country-ſeats on the ſea-ſhore fell a prey to them. They took ſlaves without number; blocked up all the ports of the republic, pillaged the city of Caieta; ſunk part of a conſular fleet at Oſtia; and having made a deſcent near Miſene, carried away the daughter of the old conſul Antonius, with ſeveral other perſons of diſtinction. They committed a variety of other depredations; and therefore Gabinius, who propoſed the above-mentioned law, was applauded for his zeal; though he had nothing in view but to procure new honours for Pompey, who had reſtored the college of tribunes to their former authority. In virtue of this law the perſon to whom the Roman people and ſenate ſhould commit the management of this war was to have a power without reſtriction, his authority was to extend over the ſeas within the ſtraits, or the pillars of Hercules, and over the countries for the ſpace of 400 furlongs from the ſea. He was alſo impowered by this law to raiſe as many mariners and ſoldiers as he ſhould think fit, to take any ſums at pleaſure out of the treaſury, and to chooſe out of the ſenate fifteen ſenators to be his lieutenants. This arbitrary and unbounded authority was to continue three years, and of courſe it occaſioned much uneaſineſs to the ſenate, who ſaw through the tribune's deſign, and ſeveral ſenators reproached Pompey with aiming at the ſovereignty of Rome. After much oppoſition, Gabinius's motion was agreed to by a great majority, and Pompey was appointed to make war upon the pirates with the title of proconſul, B. C. 66. A. U. C. 682. Pompey, in virtue of this law, was furniſhed with 500 ſhips, 120,000 foot, and 5000 horſe; and he conducted the expedition with ſo much prudence and vigour, that he cleared the ſea in four months, after having taken or ſunk 1300 according to ſome, or according to others, 846 of their veſſels, deſtroyed 10,000 of the pirates, and reduced 120 towns or caſtles on the coaſts, which they had ſeized. In this expedition the proconſul ſet at liberty an incredible number of captives, and took above 20,000 priſoners, whom he ſent to people the deſerted cities of Cilicia, *viz.* Mallus, Adena, Epiphania, and Soli, which latter he called from his own name Pompeiopolis.

GABINIUS, AULUS, in *Biography*, an ancient Roman commander, who began his public career under the dictator Sylla about the year B. C. 82. He arrived at the high honour of the conſulate in 58, and in the following year obtained the government of the rich province of Syria. Here he carried on his oppreſſions with a heavy hand; made war againſt Alexander in Judea, whom he quickly reduced to ſue for peace; re-eſtabliſhed Hyrcan in the dignity of pontiff, and ſet the government of that country upon a new ſyſtem. He then undertook, for a large ſum, to replace Mithridates on the throne of Parthia, whoſe intereſts he readily abandoned when a ſtill larger bribe was offered him by Ptolemy Auletes, king of Egypt, to aſſiſt in re-eſtabliſhing him on his throne, which had been uſurped by his ſon-in-law Archelaus. Gabinius, for the ſtipulated ſum of ten thouſand talents, half of which was paid when the agreement was made, proceeded with his army into Egypt, though it was contrary to an expreſs law for a governor to march out

of his province, or engage in a new war without the consent of the senate. He secured the passes by the horse under Marc Antony, and following immediately into the heart of the country, gave Archelaus a total defeat, and took him prisoner, but for another bribe he suffered him to escape. The ambition of Archelaus induced him again to take up arms, till at length he was slain, and Ptolemy was quietly seated on his throne. Gabinius was accused at Rome of high crimes and misdemeanors, and Cicero was employed to conduct the prosecution. Such was the indignation excited against him, that he would have been condemned in his absence, had he not been supported by the consuls Pompey and Crassus. In the year 54 he was impeached of high treason, and acquitted by a small majority: he was next tried upon two actions for corruption and extortion, and though now defended by Cicero, he was sentenced to perpetual banishment. He was obliged to expend his ill-gotten wealth in bribes to his judges, and lived abroad in poverty and obscurity, till the breaking out of the civil war between Cæsar and Pompey. Under the former he acted in the capacity of lieutenant, and marching through Illyricum, he was defeated with great loss by the people of the province, and compelled to take refuge in Salona. He did not long survive this disaster. Rom. Hist.

GABIONS, in *Fortification*, &c. are large cylindric baskets, open at both ends, made of ozier twigs, about three feet high, and as much in diameter; having nine or ten stakes, about an inch and a half in diameter, which exceed the basket-work above five or six inches, and are pointed. These serve in sieges to carry on the approaches under cover, when they come pretty near the fortification.

They are commonly used in batteries to screen the engineers, &c. in order to which one is placed on either side each gun, only leaving room for the muzzle to appear through.

There is also a smaller sort of gabions, about one foot high, twelve inches in diameter at the top, and from eight to ten at bottom, used on parapets, in trenches, &c. to cover the musketeers; being placed so close as that a musket can but just peep through.

They also serve as a parapet on lines, lodgments, &c. where the ground proves too hard to dig into.

GABIONS, *Stuffed*, are five or six feet long, and as much in diameter, filled with branches and small wood, and serving to roll before the workmen in trenches, and to cover them in front against musket-shot. See MANTLET.

To render the gabions useless, they endeavour to set them on fire, by throwing pitched faggots among them.

GABISE, in *Geography*, a town of Asiatic Turkey, in Natolia; 28 miles S.E. of Constantinople.

GABLE, in *Architecture*, is a vertical triangular plane wall, generally surmounting the flank walls, and terminating an end of the roof, which either covers the gable, or the coping of the gable runs parallel to the plane of the roof, and covers the ends of the slating or covering. The difference between a gable and pediment is this; a gable has no cornice, but a pediment is surrounded with cornices, one of which is horizontal, and the other two equally inclined to it. See PEDIMENT.

GABLE *Land* See LAND-*gable*.

GABLE *End Foreland*, in *Geography*, a cape on the E. coast of the northern island of New Zealand, in the South Pacific ocean. S. lat. 38° 15'.

GABLENZ, a town of Saxony, in the circle of Erzgeburg; 6 miles N.N.W. of Zwickau.

GABLOCK, in *Mining*, is a large iron crow or bar, used for raising large stones in a mine or quarry.

GABLOCKS, the artificial spurs of a game-cock.

GABON, in *Geography*, a river of Africa, which runs into the Atlantic, near Cape St. Clara, and gives name to a country through which it passes.

GABOONG, a small island in the East Indian sea, near the S.W. coast of the island of Palawan. N. lat. 8° 9'. E. long. 117° 20'.

GABORI, a bay on the S.E. coast of Cape Breton island; its entrance is not more than 20 leagues from the isles of St. Pierre, and lies between islands and rocks, about a league in breadth. The bay, which is two leagues deep, affords good anchorage.

GABOU, or JABOU, a country of Africa, between Benia and Dahomy, about 150 miles from the coast; the chief trade consists in slaves.

GABRANTUICI, *Bay of*, in *Ancient Geography*, is Burlington bay, on the coast of Yorkshire. Ptolemy.

GABRES, or GAVRES, a religious sect in Persia and India; called also *Gebres*, *Geures*, &c. See MAGI.

The Turks call the Christians Gabres, q. d. infidels, or people of a false religion; or rather, as Leunclavius observes, Heathens, or Gentiles: the word Gabre, among the Turks, having the same signification as Pagan, or Infidel, among the Christians; and denoting any thing not Mahometan.

In Persia the word has a more peculiar signification; wherein it is applied to a sect dispersed through the country, and said to be the remains of the ancient Persians, or followers of Zoroaster, being worshippers of fire. See FIRE, *everlasting*.

They entertain the most profound veneration for this ancient philosopher, whom they consider as the great prophet sent by God to communicate his law, and to instruct them in his will.

They have a suburb at Ispahan, which is called Gaurabad, or the town of the Gaurs, where they are employed in the meanest and vilest drudgery: some of them are dispersed through other parts of Persia; but they principally abound in Kerman, the most barren province in the whole country, where the Mahometans allow them liberty, and the exercise of their religion. Several of them fled many ages ago into India, and settled about Surat, where their posterity remain to this day. There is also a colony of them at Bombay. They are a poor, ignorant, inoffensive people, extremely superstitious, and zealous for their rites, rigorous in their morals, and honest in their dealings. They profess to believe a resurrection and a future judgment, and to worship only one God. And though they perform their worship before fire, and direct their devotion towards the rising sun, for which they have an extraordinary veneration, yet they strenuously maintain that they worship neither, but that these are the most expressive symbols of the Deity; and for this reason they turn towards them in their devotional services. See Thevenot's and Tavernier's Voyages, and Hyde's Rel. Vet. Pers. cap. xxiv.

However, some have supposed that these are Persians converted to Christianity, who, being afterwards left to themselves, mingled their ancient superstitions with the truths and practices of Christianity, and so formed for themselves a religion apart: and they allege that, throughout the whole of their system of doctrine and practice, we may discern the marks and traces of Christianity, though grievously defaced; the annunciation, the magi, the massacre of the infants, our Saviour's miracles, his persecutions, ascension, &c.

GABRI, in *Ancient Geography*, a people of Sarmatia, near the Palus-Mæotides. Pliny.

GABRIEL,

G A B

GABRIEL, St. in *Geography*, an iſland in the great river La Plata, S. America, diſcovered by Sebaſtian Cabot in the year 1526.

Gabriel, *St.* a Spaniſh miſſion and ſettlement in New Albion, firſt formed in 1773; 12 miles N. E. of Point Laſuen—Alſo, a town of Mexico, in New Biſcay; 170 miles S. S. W. of Parral.

GABRIELI, Andrea, in *Biography*, an eminent performer on the organ, maeſtro di cappella of St. Mark's cathedral at Venice in the 16th century, and a voluminous compoſer. In 1589, he publiſhed "Ricercari a quattro," the precurſors of *Fantaſie*, which ſee. Padre Martini, in the firſt vol. of his "Storia della Muſica," gives the following liſt of his vocal compoſitions; Miſſar. 6. voc. lib. i. Ven. 1570. Trelibridi Madrig. a 3. 6. voci. Ven. 1580, 1582, 1583. Mottecta 5. voc. lib. i. Venet. 1584. Pſalmi Penitent. 6. voci. Venet, 1583. Canzoni alla Franzeſe per l'Organo, Ven. 1605.

GABRIELITES, in *Eccleſiaſtical Hiſtory*, a ſect of anabaptiſts that appeared in Pomerania in 1530. They derive their name from Gabriel Scherling, who, after having been for ſome time tolerated in that country, was obliged to remove, and died in Poland.

GABRIELLI, Giovanni, in *Biography*, engaged in the ſervice of the republic of Venice, publiſhed, in 1587, Concerti Muſic di Chieſa, e Madrigali a 6, 7, 8, 10. 12. 16. voci. lib. i and ii. Intonationi d'Organo, lib. i. Ven. 1593.

Gabrielli, Catterina. Nothing having happened ſince the 4th vol. of the Gen. Hiſt. of Muſ. was publiſhed to change our opinion of the talents of this female ſinger, we ſhall extract the article from that work.

The moſt memorable muſical event of the ſeaſon of 1775 and 1776, was the arrival in London of the celebrated Catterina Gabrielli, called early in life La Cuochetinæ, being the daughter of a cardinal's cook at Rome. She had, however, no indications of low birth in her countenance or deportment, which had all the grace and dignity of a Roman matron. The firſt time her name appears in the "Indice de' Spettaccoli Teatrali," ten years before ſhe came to England, when ſhe ſung at Turin; to her name is added, *braviſſima*, and her reputation was ſo great before her arrival for ſinging and caprice, that the public, expecting perhaps too much of both, was unwilling to allow her due praiſe in her performance, and too liberal in aſcribing every thing ſhe ſaid and did to pride and inſolence. It having been reported that ſhe often feigned ſickneſs, and ſung ill when ſhe was able to ſing well, few were willing to allow ſhe could be ſick, or that ſhe ever ſung her beſt while ſhe was here; and thoſe who were inclined to believe, that ſometimes ſhe might perhaps have exerted herſelf, in pure caprice, thought her voice on the decline, or that fame, as uſual, had deviated from truth in ſpeaking of her talents. Her voice, though of an exquiſite quality, was not very powerful; and her chief excellence having been the rapidity and neatneſs of her execution, the ſurprize of the public muſt have been diminiſhed on hearing her after Miſs Davies, who ſung in the ſame ſtyle many of her ſongs, with a neatneſs ſo nearly equal, that common hearers could diſtinguiſh no difference. There were, however, a few fair and diſcriminating critics, who diſcovered a ſuperior ſweetneſs in the natural tone of the Gabrielli's voice; an elegance in the finiſhing her muſical periods or paſſages; and an accent and preciſion in her diviſions, not only ſuperior to Miſs Davies, but to every ſinger of her time. As an actreſs, though of low ſtature, there were ſuch grace and dignity in her geſtures and deportment, as caught every unprejudiced eye; indeed, ſhe filled the ſtage and occupied the attention of the ſpectators ſo much, that they could look at nothing elſe while ſhe was in view. Her freaks and *ſpi gleries*, which had fixed her character, ſeem to have been very much ſubdued before her arrival in England. In converſation ſhe ſeemed the moſt intelligent and beſt bred virtuoſa with whom we had ever converſed; not only on the ſubject of muſic, but on every ſubject concerning which a well educated female, who had ſeen the world, might reaſonably be expected to have obtained information. She had been three years in Ruſſia previous to her arrival in England, during which time no peculiarities of individual characters, national manners, or court etiquette, had eſcaped her obſervation. In youth, her beauty and caprice had occaſioned a univerſal delirium among her young countrymen, and there were ſtill remains of both ſufficiently powerful, while ſhe was in England, to render credible their former influence. With reſpect to the rapidity of her execution, it was never ſo exceſſive as to ceaſe to be agreeable; in ſlow movements her pathetic powers, like thoſe in general of performers the moſt renowned for agility, were not ſufficiently touching or effectual to occaſion diſputes concerning her *genre*. Soon after ſhe quitted England, ſhe retired to Bologna, where, if ſtill living, we hope ſhe reſides in private tranquillity, after all the ſtorms which her beauty and talents had occaſioned, while ſhe remained in the ſervice of the public.

GABRIEL-SIONITA, a learned Maronite who flouriſhed in the ſeventeenth century, was profeſſor of the Syriac and Arabic languages at Rome. From this city he went to Paris, to take a part in editing the Polyglot bible, publiſhed by M. Le Jay, and carried with him ſome Syriac and Arabic verſions tranſcribed by himſelf from MSS. The Latin tranſlations which accompany theſe verſions, excepting thoſe of the book of Ruth, were furniſhed by Sionita. After this he was appointed profeſſor royal of the Syriac and Arabic languages at Paris, and was highly eſteemed and much employed as a tutor in them. He died in the year 1648. Walton, in the Engliſh Polyglot, has copied the verſions introduced into Le Jay's by Sionita. This learned man publiſhed tranſlations of other Arabic works, and among theſe was an Arabic geography, entitled "Geographia Nubienſis." Moreri.

GABRINI, Nicholas, better known under the name of Rienzi, an extraordinary political character, was born in the fourteenth century at Rome. His father was a tavern keeper of the lower order, and named Lorenzo, which being contracted to Rienzo, the ſon was called Nicolo or Cola di Rienzo. He received an excellent education, the advantages of which he knew well how to eſtimate. He was never ſatiated with reading the beſt Roman authors, nor with ſearching into the reliques of antiquity diſperſed through his native city. He ſoon became celebrated, and the common people, who do not readily give all the credit due to a literary character, were accuſtomed to regard him as an extraordinary perſon, and to look up to him as one deſtined to redreſs thoſe wrongs of which they were deeply ſenſible; and the higher orders of the citizens viewed him with reſpect, on account of his acknowledged learning and talents. His firſt poſt was that of a public ſcribe or notary, and, in 1346, we find him joined in a deputation from the Romans to the new-elected pope Clement VI. at Avignon, for the purpoſe of exhorting him to bring back the papal court to its original ſeat. He ſpoke on this occaſion with ſo much force and real eloquence, and painted in ſuch ſtrong colours the inſolences and oppreſſions of the nobles, that high ideas were excited of his character; the pope created him an apoſtolic notary,

notary, but gave no explicit reply to the deputies. Upon his return he entered upon the exercise of his office, which he discharged with diligence and great probity, but at the same time he was attentive to foment the discontents of the people by harangues against the nobility, and against the abuses in the public administration. When men's minds were prepared for a change, he summoned his friends, and having made an energetic speech, describing the wretchedness and degradation into which the Christian capital was fallen, and from which nothing but the efforts of its own citizens could raise it, he caused them to subscribe an oath for the establishment of the "Good Estate." He had the address to gain over the pope's vicar; and at a second meeting in the capitol, he produced fifteen articles as the basis of the "Good Estate," which were unanimously approved, and the people conferred upon him the title of tribune, with the power of life and death, and all the other attributes of sovereignty. The governor of the city, Colonna, who had been absent some time, returned, and at first threatened him with punishment, but quickly found that the power of the state was taken out of his hands, and that he himself must seek for security by flight. Rienzi banished him with the principal noble families of Rome, and some, who had been convicted of great oppression, were put to death. In the first exercise of his authority he seems to have had no other view than the promotion of the public good; he chose honest and honourable men at the head of the administration, and he purged Rome of those enormities that had long prevailed in it. His power was sanctioned by the pope, and his reputation was soon extended through the whole of Italy; the messengers whom he sent to propose to the different states a general league, were every where received with high respect, though unarmed, and only distinguished by a silver wand, and honourable embassies were sent to him in return. The king of Hungary and the emperor solicited his friendship, and it was imagined, by his more eager partizans, that he was to be an instrument in the hands of providence, for restoring the ancient grandeur of Rome and Italy. Among the most eager of his friends was the celebrated Petrarch, who had contracted an admiration for his character, when joined with him as one of the deputies to the pope; by the poet he was exhorted to proceed in his glorious undertaking, but his success was more than he could bear. He assumed a variety of titles, issued a letter declaring Rome the head of the world, and he even ventured to cite the two rival emperors, Charles and Lewis, and the electors, to appear before him, and justify their several pretensions. He dismissed the pope's legate, reduced the nobles to a state of humiliation, and established a reign of terror. He now found, that those who had been most friendly to his cause, while he acted with prudence and moderation, were the first to desert his standard, when that standard was attempted to be reared on the rights of the people. Finding that he had lost the affection and confidence of the people, he withdrew from Rome, and, in the beginning of the year 1348, took refuge in the kingdom of Naples, and was obliged to live concealed in a hermit's cell till the commencement of 1350. He now took advantage of the jubilee to return secretly to Rome, where being discovered, he withdrew to the king of the Romans at Prague. After this he fell into the hands of pope Clement at Avignon, who threw him into prison, and appointed a commission of three cardinals to try him; but upon the death of that pope, his successor, Innocent VI. released him from confinement, and sent him to Rome, in order to oppose an insurgent who had seized the government of that capital. The Romans received him again with great demonstrations of joy, and he even recovered his former authority, which, however, he held but a short time, when the nobles found means to excite a sedition against him, in which he was massacred, in October 1354. His dead body was treated with the greatest indignity by the people; and "his end," observes the biographer, "adds one more example, to the many recorded by history, of the usual fate of popular leaders and reformers." He possessed an union of fanaticism with artifice; and was more courageous in speech and council than in action. His original intention was unquestionably good, but neither his temper nor understanding was adequate to the greatness of his enterprize. He wanted presence of mind in emergencies of danger, and he is said to have betrayed a shameful timidity in the last scene of his life.

GABRIS, in *Ancient Geography*, the name of two towns in the interior of Media. Ptolemy.—Also, a place in Gaul, which lay, according to the tables of Peutinger, in the route from Cæsarodunum to Avienum. M. d'Anville refers it to Chabris, N. W. of Bourges.

GABRITA, or GABRETA, a forest, between which and the mountains of the Sarmatians lay the Hercynian forest, which see.

GABRITA, *Sylva*, a forest which lay on the S. W. of Bohemia, where a chain of hills now divides it from Bavaria.

GABS, a town of Africa, in the S. E. part of Tunis, in a bay of the Mediterranean, called the Lesser Syrtis, anciently called "Tacape," and by Scylax "Epichus," of which ancient city a heap of ruins still remains, with some beautiful granite pillars, square, and about 12 feet in length. The old city, where these ruins are found, was built upon a rising ground, at half a mile's distance from the new, having been formerly washed by the sea, which here formed itself into a bay of nearly half a mile in diameter. But at present the greatest part of this bay is filled up, and gained from the sea, which, from the great shallowness of it and daily reception of mud and roots from the river, will easily submit to such alterations and encroachments. At Gabs are several plantations of palm-trees. The chief branch of trade at present consists in the Al-hennah, which is plentifully cultivated in all their gardens; this beautiful, odoriferous plant grows 10 or 12 feet high, putting out its flowers in clusters, which yield a smell like camphor; the leaves are used by the African ladies to tinge their hair, hands, or feet of a tawny saffron colour, by them esteemed beautiful. Gabs lies at the distance of 170 miles S. from Tunis. N. lat. 34. E. long. 10° 2'. Shaw's Travels, p. 113.

GACE', a town of France, in the department of the Orne, and chief place of a canton, in the district of Argentan; 13 miles E. of Argentan. The place contains 1186, and the canton 7640 inhabitants, on a territory of 152½ kiliometres, in 18 communes.

GAD, TRIBE OF, in *Scripture Geography*, a district of Palestine, which lay on the north side of Reuben, having the Jordan on the west, the Ammonites on the east, and the half tribe of Manasseh on the north, reaching from 32° 5' to 32 50' of latitude, and from 36 15' to almost 37° east longitude. It was no less rich and fertile than that of Reuben, especially in pasture grounds. Its chief towns were Mahaneim and Penuel, both so named by Jacob, Succoth, where he built his booths, Mispha, or Maspha-Rabba, the metropolis of Bashan, since called Ribboth, and more lately Philadelphia, Ramoth-Gilead or high lands of Gilead, Rogelim, the native place of good old Barzillai, Thishbi, Sharon, Sophar, Armon, Mogesh, Debbir or Dabbir,

Dabbir, Aſhtaroth, Jazer or Jahſor, Dibbon, Aroer, Beth-Haran, and Enon, the place where John baptized; which laſt was on the eaſt bank of Jordan, between that and Salim, about eight miles S. of Scythopolis.

GAD, in *Mining*, an inſtrument uſed to dig out the ore. It is a ſmall punch of iron with a long handle of wood. One of the miners holds this in his hand, directing the point to a proper place, while the others ſtriking it with a large ſledge hammer, drive it into the vein.

The working by this inſtrument is thence called gading.

GAD, in *Rural Economy*, a term uſed to ſignify a rod with a leathern thong applied to the end of it, and which was formerly much employed in driving ox teams. In ſome caſes it had likewiſe a prick fixed in the contrary end of it, in order to force the animals more powerfully in their work.

GAD-*fly*, in *Entomology*. See OESTRUS.

GADAMIS, or GHEDEMES, in *Geography*, a country of Africa, W. of Fezzan and 100 leagues from the Mediterranean; it is ſaid to contain 92 villages. The capital bears the ſame name. N. lat. 30° 40'. E. long. 10° 25'.

GADARA, in *Ancient Geography*, a town of Paleſtine, in the half tribe of Manaſſeh, on the other ſide of Jordan, 60 ſtadia from the lake of Tiberias. It was the capital of Peræa, and regarded, according to Polybius, as the ſtrongeſt town of the country. Epiphanius mentions its warm baths.

GADDESDEN, JOHN OF, in *Biography*, a phyſician, who lived in the early part of the fourteenth century, and appears to have had very extenſive and lucrative practice. He was the firſt Engliſhman who was employed as a phyſician at court, being appointed to that office by Edward II.: before his time the king's phyſicians had been excluſively foreigners. The ignorance, ſuperſtition, and low quackery, however, which appear throughout his practice, and which are painted with much life and humour by Dr. Freind, do no great honour to the character of the profeſſion in that age. Nevertheleſs, he came forward as an univerſal genius; beſides aſſuming the characters of philoſopher, philologiſt, and poet, he undertook every thing that lay within the circle of phyſic and ſurgery. He talks of his experience in manual operations, pretends to be very expert in bone-ſetting, and profeſſes himſelf a great oculiſt. He alſo acquaints us with his great ſkill in *phyſiognomy*; "and did deſign, if God would give him life and leiſure, to write a treatiſe of *chiromancy*;" but to our unſpeakable grief, this excellent comment upon fortune-telling is loſt. He was a great dealer in ſecrets, and ſome he had which were the moſt ſecret of ſecrets, and did miracles. But his chief ſtrength lay in receipts, and without giving himſelf much trouble in forming a judgment reſpecting the nature of the caſe, he ſeemed to think that, if he could muſter up a good number of theſe, he ſhould be able to encounter any diſtemper. He ſeems to have neglected no ſtratagems, by which he might ſurpriſe and impoſe on the credulity of mankind, and to have been very artful in laying baits for the delicate, the ladies, and the rich (pro delicatis, pro dominabus, pro divitibus). When he was employed in attending the king's ſon, in the ſmall-pox, in order to ſhew his ſkill in inflammatory diſtempers, he, with a proper formality, and a countenance of much importance, ordered the patient to be wrapped up in *ſcarlet*, and every thing about the bed to be of the ſame colour. This, he ſays, made him recover without ſo much as leaving one mark in his face; and he commends it for an excellent mode of curing. Nevertheleſs this man was praiſed by Leland, Ovaringius, and others, as a profound philoſopher, a ſkilful phyſician, and the brighteſt man of his age.

His only work, which he produced while reſident at Merton college, Oxford, is the famous "Roſa Anglica," which compriſes the whole practice of phyſic; collected indeed chiefly from the Arabians, and the moderns who had written in Latin juſt before him, but enlarged and interſperſed with additions from his own experience. Its title is "Roſa Anglica quatuor Libris diſtincta, de morbis particularibus, de Febribus, de Chirurgia, de Pharmacopœa." Dr. Freind obſerves, that John ſeems to have made a collection of all the receipts he had ever met with or heard of; and that this book affords us a complete hiſtory of what medicines were in uſe, not only among the phyſicians of that time, but among the common people in all parts of England, both in the empirical and ſuperſtitious way. Dr. Aikin remarks that the method of producing freſh from ſalt water by *ſimple diſtillation* ("in an alembic with a gentle heat") is familiarly mentioned by this author, even at ſo remote a period.

Although devoted to the practice of his profeſſion, he was prebendary of St. Paul's, in the ſtall of Ealdland. It ſeems probable from this and other inſtances, that the procurement of a ſinecure place in the church was a method in which the great ſometimes paid the ſervices of their phyſicians. See Freind, Hiſt. of Phyſic, part ii. Aikin, Biograph. Mem. of Med. p. 9.

GADDI, TADDEO, an hiſtorical painter, who flouriſhed at a very early period of the reſtoration of the art. He was born at Florence in 1300, and became a diſciple of Giotto, whoſe manner he imitated, and to which he ſuperadded improvement in colouring. He poſſeſſed very conſiderable talents as a man of learning; and was highly reſpected. His productions were very numerous. The moſt conſiderable of them is the altar piece in the church of Spirito Santo at Arezzo; where he painted in freſco the Crucifixion of our Saviour. He died of a fever in 1350.

GADE, in *Geography*, a river of England, which riſes in the north part of Hertfordſhire, and runs into the Coln, near Rickmanſworth.

GADEBUSCH, a town of Germany, in the duchy of Mecklenburg; 16 miles W.N.W. of Schwerin. N. lat. 53° 45'. E. long. 11° 14'.

GADELONITIS, in *Ancient Geography*, a country of Aſia, on the other ſide of the mouth of the river Halys, according to Strabo.

GADEN, in *Geography*, a town of Auſtria, 10 miles S.W. of Vienna.

GADENI, in *Ancient Geography*, a people of the Britiſh iſland of Albion, according to Ptolemy; and ſuppoſed by Camden to have poſſeſſed Tiviotdale, Twedale, Mers, and the Lothians. It is, however, more probable, that they were a ſmall nation, inhabiting the more deſert and mountainous parts of Tiviotdale and Northumberland. Baxter imagines that their name was derived from the Britiſh word "Gadaii," which ſignifies to fly.

GADEROW, in *Geography*, a town of Hindooſtan, in Guzerat; 42 miles E. of Junagur.

GADEROWS CHOULTRY, a town of Hindooſtan, in the Carnatic; 17 miles S.S E. of Tanjore.

GADERSLEBEN, a town of Germany, in the principality of Halberſtadt; 20 miles E. of Halberſtadt.

GADES, in *Ancient Geography*, *Cadiz*, a town of Spain, at the mouth of one of the arms of the river Boetis. This town ſeems to have exiſted before the eſtabliſhment of the Phœnicians, and to have been enlarged by them, and rendered a flouriſhing place of commerce. Its firſt name, given to it by the Celtes, the natural inhabitants of Spain, previouſly to the arrival of colonies of ſtrangers, is ſaid to have been "Cotinuſa;" but when the Phœnicians eſtabliſhed

bliſhed themſelves in this town, more than 1500 years before the vulgar era, they called it "Gaddir," an encompaſſed place, with reference probably to a wall which ſurrounded and defended it. According to Pliny and Strabo there were in this place two iſlands; one, in which was ſituated "Gades," and called by its name, and the other denominated "Erithia" and "Aphrodiſias," or the "iſle of Juno." Some authors have ſuppoſed that this place was alſo called "Tarteſſus;" but others, among whom is M. D'Anville, have been of opinion that Tarteſſus or Tarteſſa was the name of the country, or at leaſt of an iſland formed by the Guadalquivir near its mouth. The town of Gades was alſo called in later times "Auguſta urbs Julia Gaditana;" and towards the end of the republic it was very populous, inſomuch that it vied with Rome in reſpect of number of inhabitants. L. Cornelius Balbus, who was of this town, contributed very much to the aggrandizement of it, and conſtructed an arſenal for it on the continent. When the Carthaginians made themſelves maſters of a great part of Spain, the town of Gades was ſubjected to their dominion; and Livy expreſsly ſays, that Aſdrubal, in the year of Rome 545 or 546, retired hither in order to avoid falling into the hands of Scipio. After the death of the two Scipios, L. Marcius Septimius, having been made general by the choice of the ſoldiers, concluded a treaty of alliance with the inhabitants of Gades, or the Gaditani, who had afforded very conſiderable ſuccours. Gades has furniſhed a great number of medals.

The Tyrian Hercules had a magnificent temple at ſome diſtance from this city, on the eaſt of the iſland, near the main land. This temple was very famous; its ſituation in ſo remote a place, its antiquity, the incorruptible timber of which it was conſtructed, its pillars enriched with ancient inſcriptions and hieroglyphics, the labours of Hercules, which were there repreſented; Geryon's trees, which, according to Philoſtratus, diſcharged blood; the old ceremonies that were practiſed; all theſe made it very celebrated, and Gades thought itſelf ſecure under the protection of ſo great a heroe. Accordingly, as Theron, the king of Spain, was coming to rifle this temple, a panic terror diſperſed his ſhips, upon the ſudden appearance of fire from ſome unknown cauſe. See HERCULES.

GADIAG, in *Geography*, a town of Ruſſia, in the government of Tchernigov; 112 miles S.E. of Tchernigov. N. lat. 50° 24'. E. long. 33°.

GADIBUNDA, a town of Hindooſtan, in Myſore; 13 miles N. of Chinna Balabaram,

GADITCH, one of the 11 diſtricts of the government of Tchernigov in Ruſſia, ſituated on the Pſol.

GADOLINITE, in *Mineralogy*, a foſſil thus named in honour of profeſſor Gadolin, who diſcovered in it the exiſtence of a new earth, called Yttria.

Its colour is an intenſe black, which more or leſs inclines to browniſh black.

It occurs maſſive and diſſeminated, as alſo, though rarely, in a regular form. Haüy ſuppoſes its fundamental form to be a rhomboidal oblique priſm; which is a primitive form different from that of any other mineral ſubſtance.

The ſecondary form, from an incomplete cryſtal, appeared to the ſame celebrated author to be a ten-ſided priſm, terminated by three planes.

Internally it is ſhining, and its luſtre is perfectly reſinous. Fracture more or leſs conchoidal. Fragments indeterminately angular, with ſharp, ſcarcely tranſlucent edges. Its hardneſs is nearly that of quartz. It is brittle. Specific gravity 4.04.

Gadolinite manifeſts a conſiderable action on the magnetic needle. Before the blow-pipe it decrepitates; but if gradually expoſed to the heat thus produced, ſmall fragments will remain entire, and undergo partial fuſion. Glaſs of borax is coloured yellow by it.

When reduced to powder, and heated with nitric acid, it is converted into a yelloviſh grey gelatine.

The proportions of its conſtituent parts are differently ſtated by Eckeberg, Vauquelin, and Klaproth.

Eckeberg.	
Yttria	47.5
Silica	25.0
Iron	18.0
Alumina	4.5
Loſs	5
	100

Vauquelin.	
Yttria	35.
Silica	25.5
Iron	25.0
Oxyd of manganeſe	2.0
Lime	2
Water and carb. acid	10.5
	100

Klaproth.	
Yttria	59.75
Silica	21.25
Black oxyd of iron	17.50
Alumina	0.50
Water	0.50
Loſs	0.50
	100

Prof. Eckeberg has ſince repeated his experiments, and is ſaid to have found the reſults ſtill more diſcordant. But fortunately the external and phyſical characters of this ſubſtance are ſufficiently marked to diſtinguiſh it from any other that might be miſtaken for it.

It is found at Ytterby, in the diſtrict of Roſlagen, in Sweden, imbedded in feldſpath, with mica; and is accompanied by yttro-tantalite, another ſubſtance of which the yttria above-mentioned forms a conſtituent part.

GADOU, GADOUA, or GADUA, in *Geography*, a country of Africa, on the S. ſide of the river Senegal, containing mines of gold, iron, and ſalt-petre. N. lat. 12° 10' to 13° 10'. W. long. 7° to 9°.

GADUS, in *Ichthyology*, a genus of the Jugular tribe, the head of which is ſmooth; gill-membrane with ſeven ſlender rays; body oblong, covered with deciduous ſcales; all the fins covered with a common ſkin; dorſal generally more than one; the rays unarmed; ventral fins ſlender and ending in a point.

The ſpecies are divided into three ſections according to the number of the dorſal fins, and the preſence or abſence of the beards at the mouth.

* *Dorſal fins three, mouth bearded.*

CALLARIAS. Colour various; tail equal; upper jaw longer. Gmel. *Gadus balthicus, Torſk*, It. Oel. *Gadus callarias balthicus*, It. Scan. *Aſellus varius vel ſtriatus*, Jonſt. *Baltic Torſk, or Dorſe.*

Inhabits the Baltic, and other ſeas in the north of Europe. Like moſt others of the genus, it feeds on ſmaller fiſhes, crabs, and worms, in purſuit of which it ſometimes enters the mouths of rivers. Otto Fabricius found in the ſtomach of this ſpecies the ſea ſcorpion (cottus ſcorpio), and the ſand launce (ammodytes tobianus) beſides crabs, and various kinds of ſea-worms. Commonly this fiſh weighs about two pounds, or rather leſs; near Rügenwalde they have been taken from ſeven to eight pounds in weight, and

ſometimes

ſometimes even twelve or fourteen pounds. Schoneveld ſpeaks of one four feet long.

The ſpawning ſeaſon is in January and February. The fleſh is white, tender, and well flavoured. The Icelanders take it in great plenty, and ſalt and dry it as an article of commerce. When thus prepared they give it the name of *Titteling*. This fiſh is known under various denominations in the north of Europe; in Germany it is called *Dorſch*, in Sweden *Torſk*, and in Denmark *Sma-Torſk*; the Pruſſians call it Pamuchel, and at Hamburgh it is known by the name of Scheibendorſch; the Norwegian name is Tare-Torſk, and the Lapland Tare-Torſk, and Rod-Torſk.

The general colour of this fiſh is cinereous above, and white beneath, the former ſpotted with brown, and ſometimes in the young fiſh with orange; the upper jaw is longer than the lower, and the tip of the lower jaw furniſhed with a beard or cirrus.

Morhua. Tail ſomewhat equal; firſt anal ray ſpinous. Linn. *Cabliau*, Ström. *Gadus ſquamis majoribus*, Bloch. *Morhua*, Bellon. *Molva vel morhua*, Rondel. *Cod, cod-fiſh*. Will. Ray. Donov. Br. Fiſhes.

The cod attains to the length of four or five feet, and ſometimes rather more. The body is of moderate thickneſs, with the abdomen prominent; the head of middling ſize, with the opening of the mouth large, and the jaws and palate armed with numerous ſharp teeth. The colour of the body variable, according to the age of the fiſh, in general cinereous on the back and ſides, and ſpotted more or leſs conſpicuouſly with dull yellow. The lateral line broad and whitiſh.

Smaller fiſhes, crabs, and worms, of various kinds, are the chief food of the cod: it is a creature of moſt voracious appetite, frequently preying on its own ſpecies, and its digeſtion ſo powerful, as to diſſolve many of the harder ſubſtances which it devours. Stones or pebbles are frequently found in its ſtomach; and theſe it is ſuppoſed to ſwallow to allay hunger, by retaining the ſtomach in a diſtended form. It is a highly prolific fiſh, nearly a million of eggs being ſometimes contained in a ſingle roe.

This well-known ſpecies occurs in immenſe abundance throughout all the northern ſeas of Europe, in the vicinity of the polar regions, from whence they migrate towards the ſouth, at particular ſeaſons, in queſt of food. Though there are many extenſive fiſheries of cod in the north of Britain and Ireland, the principal are thoſe carried on upon the banks of Newfoundland, the concerns of which are truly prodigious. They are taken only with the hook and line; and being cured, or ſalted, and dried upon the ſpot, are thence tranſported to the continent of Europe. See *Cod* Fishery.

Æglefinus. Whitiſh; tail forked; upper jaw longeſt. Linn. *Gadus kolja*, It. Scan. *Æglefinus*, Bellon. *Aſellus major*, Aldrov. *Haddock*, Will. Donov. &c.

The haddock is a general inhabitant of the northern ſeas of Europe, and grows to the length of three feet; it ſeldom, however, exceeds half that length, or about ſeven pounds in weight. The head is cuneated, and the mouth narrower than in others of its tribe; the eyes large, with black pupil and iris ſilvery. Its colour is pale-greyiſh, tinged with brown above, and ſilvery-white beneath; the lateral line nearer the back, and of a black colour, and the fins partaking of a tinge of blueiſh-grey. There are three fins on the back of this fiſh; the firſt containing about fourteen rays, the ſecond twenty-ſix rays, and the third eighteen; in the firſt of the two anal fins twenty-two rays, in the ſecond twenty, and in the tail from thirty to forty.

At certain ſeaſons of the year, the haddocks aſſemble together in immenſe ſhoals in the northern ſeas, preparatory to their annual migration to the ſouthward, in the courſe of which they viſit the coaſts of the Britiſh iſles. Some time after their appearance in the German ſea, they are equally abundant upon the coaſt of Sweden, Denmark, and Holland, and on the ſhores of Britain; but after paſſing down the channel to the ſouthward, as far as the coaſt of France, it is not certain that they proceed any further in that direction. It has been obſerved, that in thoſe periodical migrations which take place in the winter ſeaſon, about the end of November, or beginning of December, it never enters the Mediterranean; neither does it appear in the Baltic, or even paſs the ſound towards that ſea: Copenhagen, and other markets on the coaſt of the Baltic, and alſo Hamburgh, being ſupplied with the haddock by the fiſhermen, who take them in vaſt quantities in the ſea, off Heligoland.

The haddocks are in full roe at the time of their arrival on our coaſt in December, nature having directed them to ſeek a milder region than that which they inhabit in ſummer, as the winter approaches, in order to depoſit their ſpawn. The old fiſhermen affirm, that the females appear in ſhoals upon the coaſt, which, after laying their eggs, are followed to the ſame places by ſhoals of the males, who fecundate the eggs depoſited by the former.

Haddocks of a large ſize are only eſteemed good for the table during the winter; thoſe of a ſmall ſize, before they begin to breed, are conſidered in perfection at all times; but theſe even are beſt in winter. The fleſh of this fiſh, when boiled, is not ſo firm as that of the cod, to which it muſt alſo yield in the excellence of flavour; though ſome, however, think it preferable. When ſalted and cured, like the cod, the haddock is by no means indifferent eating.

Upon the firſt approach or appearance of a ſtorm, the haddocks ſink to the bottom of the ſea, to ſeek ſhelter till the danger is over; and when they again appear near the ſurface, on the return of fine weather, they are obſerved to have their backs ſoiled with mud, or ſea-weeds, and other marine refuſe lodged at the bottom of the water. In the north ſeas the fiſhermen are moſt ſucceſsful in their fiſheries for the haddock during the night-time, theſe fiſhes lurking at the bottom of the ſea in the day time, but riſing near the ſurface, as the evening cloſes, in queſt of food.

Bloch is of opinion, that the black, or duſky colour of the lateral line, in addition to the little cirrus, or beard, at the lower jaw, is a ſufficient ſpecific criterion of the haddock. There is alſo another very remarkable character of the haddock, a large ſquare, or duſky ſpot, on each ſide of the body, near the head, or a little below the firſt dorſal fin, from whence, in the legends of credulous devotion, it has been admitted to be the ſame fiſh as St. Peter caught with the tribute money in its mouth. The two ſpots are conſidered as the mark of St. Peter's thumb and finger, which has ever ſince remained impreſſed on the ſides of the whole race of haddocks, to perpetuate the circumſtance. But it may be added, that the haddock is not without a rival in the reputed proof of ſanctity, the ſides of the dory being even more diſtinctly marked than thoſe of the haddock. Donov. Brit. Fiſhes, pl. 59.

Barbatus. Lower jaw with ſeven punctures each ſide. Linn. *Gadus corpore lato*, Bloch. *Aſellus latus Liſteri*, Will. *Whiting pout*, Donov. Br. Fiſhes, &c.

A marine fiſh, confined to the northern parts of Europe, and which rarely exceeds the length of eighteen inches. The body is white; the back tinged with brown; the head ſmall; mouth large; upper jaw longer; teeth very ſmall, and in both jaws; lips cartilaginous, and connected by a

common

common contractile ſkin; tongue ſhort, thick; rough on the poſterior part; the back much arched; vent nearer the head.

Luscus. Firſt ray of the ventral fin ſetaceous. Linn. *Bib*, Donov. Brit. Fiſhes.

The body of this fiſh, like that of the whiting pout, is deep, and the ſides compreſſed; the colour along the back olive; the ſides beautifully gloſſed with a tinge of golden hue, and the lower part pure ſilvery-white. The eye is protected by means of a looſe membrane, which the creature can blow up at pleaſure like a bladder. All the fins, except the ventral, are duſky, the latter white. In the firſt dorſal fin are about thirteen rays, in the ſecond twenty, and in the third nineteen; in the pectoral fins ſixteen; ventral five; firſt anal twenty-three, ſecond anal twenty, and tail thirty-three.

This ſpecies is a native of the European ſeas, and rarely exceeds the length of ten or twelve inches: it appears to be more abundant on the Britiſh ſhores, and ſtill higher northern latitudes than towards the ſouth.

Minutus. Vent in the middle of the body. Müll. *Merlangus*, Bellon. *Anthiæ ſecunda ſpecies*, Geſn. *Aſellus mollis minor*, Will. *Poor*.

Native of the European and Mediterranean ſeas; length ſix or ſeven inches, and of a ſomewhat elongated form; the body ſilvery, ſpotted with black; back browniſh-yellow, and gill-covers punctured; the lower jaw is ſhorter, with fewer rows of teeth; the eyes round and ſilvery, and pupil black; the lateral line narrow and ſtraight; and the tail forked. The abdomen perfectly black within, being lined with a ſkin of that colour.

The appearance of this little fiſh in the Mediterranean excites great joy among the fiſhermen, as it announces an abundant fiſhery, the ſhoals of the poor being immediately followed by an immenſe multitude of the voracious fiſhes, among which the cod, the dorſe, and the haddock, are the moſt conſiderable. It is known at Marſeilles, where, at certain ſeaſons, it occurs in amazing plenty, by the name of *capelan*, or *officier*. The ſpecies feeds on ſmall fiſhes and crabs, and lives, for the moſt part, in deep waters of the ſea: the fleſh is white and well-taſted.

Saida. Fourth ray of the firſt dorſal fin, and fifth ray of the firſt anal fins longer than the reſt; ſecond ray of the ventral fin ending in a long briſtle. Lepechin. *Saida gadus*.

Deſcribed as a new ſpecies in the Tranſactions of the Royal Society of Peterſburg, by Lepechin, who informs us that it inhabits the White ſea. The length is eight inches; the head of a ſomewhat compreſſed form in front, and rounder behind. The crown black; jaws armed with ſharp, ſetaceous teeth, which are barbed backwards, the upper more obtuſe, the lower more pointed, and a little longer. The eyes are large, with whitiſh pupil, and blueiſh iris; gill-covers ſilvery, ſpotted with black, and compoſed of three laminæ, the loweſt of which is lunate, the next elliptical, the third triangular, and bicuſpidate. The back of the fiſh is convex, ſlightly channelled on the fore part, and of a dirty white colour, with a few confluent blackiſh ſpots; ſides blueiſh, and belly white. The lateral line is ſtraight, and nearer the back; dorſal fins triangular, brown, with whitiſh rays; anal oblong and triangular, with the fore-part of the baſe duſky blue; ventral whitiſh at the baſe, and tail forked. The fleſh is often eaten though dry and tough.

Blennoides. Ventral fins bifid. Pallas. *Blennoid gadus*.

Native of the Mediterranean ſea. The length of this ſpecies is nine inches; the body thick, ſoft, convex, compreſſed, and covered with ſmall ſcales; ſilvery white, and grey towards the back. The head is thick, conic and obtuſe; lips fleſhy, and doubled; teeth minute, unequal, and thoſe in the upper jaw hardly viſible; tongue fleſhy, pointed, prominent, and acute at the edge; palate longitudinally ſtriated; eyes large, with ſilvery iris; gill-covers ſoft; lateral line arched on the fore-part; fins yellowiſh, with very ſmall rays, the dorſal and anal reclined; firſt dorſal fin narrow, and triangular; ſecond narrower; third rather broader and ſhorter; pectoral fins narrow, ſub-falcate, very thin; firſt ray of the ventral fins long, very thick, and bifid; firſt anal fin rounded, ſecond triangular, and tail forked.

** *Dorſal fins three; mouth without beards.*

Virens. Back greeniſh; tail forked. Linn. *Le gade ſey*, Boſc. *Green pollack*.

Gadus virens cloſely reſembles the common pollack, from which it differs in being of a greeniſh colour above, in having the jaws equal; the lateral line ſtraight, and the tail forked. The ſpecies is figured in the work of Aſcanius (p. 3. pl. 21.) This fiſh was long confounded with the common pollack: it is abundant in the northern ſeas, and is known on the coaſt of Norway by no leſs than five different appellations, in its various ſtates of growth. The firſt dorſal fin uſually contains about thirteen rays, the ſecond twenty, and the third nineteen; the pectoral ſeventeen; ventral ſix; firſt anal twenty-four, ſecond twenty, and tail forty.

Merlangus. White; back browniſh; upper jaw longeſt. Donov. Brit. Fiſhes. *Gadus merlangus; albus, maxilla ſuperiore longiore*, Linn. Fn. Suec. *Aſellus mollis*, Jonſt. *Whiting*.

A ſpecies abundant in all the temperate parts of Europe. It is found in the Baltic, Mediterranean, and Northern ſeas, although leſs frequently than in the ſeas that waſh the ſhores of Holland, France, and England, where, at moſt ſeaſons of the year, it is found in great plenty. One circumſtance is worthy of obſervation; the fiſheries for the whiting commence upon the coaſt of France as early as January or February, but on thoſe of Holland, and our own country, not before April or May.

The whiting preys on the ſprat, and the young of the herring, and other fiſhes, crabs, and worms. The ſpawning ſeaſon is in the beginning of the winter, and the young fry make their appearance ſhortly after; theſe increaſe rapidly in ſize till they become ten or twelve inches in length; after which the progreſs of their growth is obſerved to be much ſlower. There are conſiderable whiting fiſheries on the weſtern coaſt of Britain; but the largeſt whitings brought to our markets are thoſe caught in the Dutch ſeas, off the Dogger bank, theſe weighing from four to five pounds, or, ſome ſay, even eight.

The general form of the whiting is ſo well known, as to render its deſcription ſuperfluous. The dorſal fins are three in number, the firſt of which contains about fifteen rays, the ſecond twenty, and the third twenty-one. In the pectoral fin are ſeventeen rays, and in the ventral ſix. In the firſt of the two anal fins are thirty-two rays, in the ſecond twenty, and in the tail thirty-three. Brit. Fiſhes, pl. 36.

Pollachius. Lower jaw longeſt; lateral line bent. Gmel. *Aſellus huitingo-pollachius*, Will. *Whiting pollack*, Ray. Donov. Brit. Fiſhes.

Frequent on ſeveral of the rocky coaſts of Britain, and other parts of Europe. They migrate in large ſhoals, and feed on ſmaller fiſhes, eſpecially the ſand launce. The whiting pollack ſeldom exceeds the length of eighteen inches.

Its

Its head is narrow on the fore part, the eyes large and ſomewhat prominent; the body ſub-olivaceous above, becoming gradually white or ſilvery on the belly; the fins rather duſky, except the ventral and pectoral, which incline to yellowiſh, and the tail in a ſlight degree forked. It is a fiſh in much eſteem for the table.

Carbonarius. Lower jaw longeſt; lateral line ſtraight. Gmel. *Callarias imberbis*, Klein. *Aſellus niger ſive mollis nigricans*, Ray. *Le gade colin*, Buff. *Coal-fiſh*, Penn. Donov. Brit. Fiſhes, &c.

The coal-fiſh is an inhabitant of many of the rocky coaſts of Britain, and is eſpecially abundant towards the northern parts of the iſland, as it is alſo throughout the North and Baltic ſeas, and even according to Gmelin in the Pacific ocean. In different ſtages of growth the colours of this fiſh vary rather conſiderably. When young, a certain duſkineſs prevails in the colours, which becomes darker as the fiſh grow older; and when they have attained their full ſize, which is from about two to three feet, the back, noſe, dorſal fins and tail oftentimes appear of a deep black. Under the pectoral fins is a black ſpot: the mouth is alſo of the ſame colour, and the tongue ſilvery.

According to Mr. Pennant, the young of this ſpecies ſwarm about the Orkneys and the coaſt of Yorkſhire; in the former of which they conſtitute the chief ſupport of the poor: and the ſame writer further ſtates that the fry is known by different names in different places; at Scarborough they are called parrs, and when a year old, billets. Though this information may be correct, we cannot avoid expreſſing our ſuſpicion that it is the fry of the ſalmon and not the coal-fiſh to which Mr. Pennant alludes in detailing the hiſtory of the latter ſpecies. Nothing at leaſt can be more evident than that the *parr* of this author, and to which he refers as the young of Gadus carbonarius, is no other than the fry of the ſalmon. Vide Brit. Zool. Deſcription of the *Parr*, No. 78, and figure of the *Parr*, plate 66. No. 78.

The Linnæan character of the fiſh is conciſe; Bloch conceives the blackneſs of the mouth and ſtraightneſs of the white lateral line ſufficient to diſcriminate the ſpecies. The ſkin of the coal-fiſh is covered with very ſmall oblong ſcales. It has three dorſal fins, in the firſt of which are about fourteen rays, in the ſecond eighteen, and in the third twenty; in the pectoral fin eighteen; ventral five; firſt anal fin twenty-ſix; ſecond twenty, and in the tail thirty-three, beſides ten very ſhort ones on each ſide; the tail is broad and forked. Donov. Brit. Fiſhes.

Merluccius. Beardleſs; the lawer jaw longeſt. Linn. *Aſellus*, Plin. *Aſellus primus*, Will. *Hake*, Penn. Donov. Brit. Fiſhes.

The hake is a native of the North and Mediterranean ſeas. It is of the migratory kind, frequenting our ſhores in immenſe ſhoals during the mackarel and herring ſeaſons, appearing for the firſt time in June, and then again in September, in purſuit of thoſe fiſhes. The fleſh of the hake, though firm and white, is in little eſteem for its flavour, and is ſeldom eaten except by the lower orders of people. They are caught on our coaſts chiefly for the purpoſe of ſalting and drying them for exportation. Vaſt quantities, it is ſaid, are ſent every year to the port of Bilboa, and other parts of Europe. When cured it is well known by the name of Poor John, or ſtock-fiſh.

On the coaſt of France, the hake is alſo taken in great abundance, and is cured, as in England, for exportation. By one of the French writers it has been remarked, that ſince the great naval engagement in 1759, between the French and Engliſh, the hake has been found in vaſt numbers at all ſeaſons of the year, in the ſea that waſhes the ſhores of Belleiſle; and he conjectures that they were firſt attracted to that ſpot in particular by the number of dead bodies that were here committed to the deep on that memorable occaſion. Some of the hake on that coaſt we are told meaſure ſix or ſeven feet in length.

The hake is a moſt voracious fiſh, and beſides feeding, as before obſerved, on the mackarel and herring, preys alſo on other ſmall fiſh, crabs and worms. For its carnivorous mode of life its teeth are perfectly well adapted, for theſe are numerous, ſtrong, ſharp, and much recurved, which give it no ſmall degree of advantage in ſecuring its prey. The eggs found in the body of the female are of an orange colour, and about the ſize of a grain of millet.

The form of this fiſh is not inelegant: the head is long and rather depreſſed. In the firſt dorſal fin are nine rays, in the ſecond thirty-eight; pectoral fin fifteen rays; ventral eight; anal thirty-ſix; and in the tail eighteen.

Molva. Mouth bearded; upper jaw longer. Linn. *Gadus longa*, It. Wgoth. *Gadus droſo dipterygio, maxilla ſuperiore longiore*, Bloch. *Enchelyopus*, Klein. *Aſellus longus*, Will. *Ling*, Donov. Brit. Fiſhes, &c.

A northern fiſh, bearing a remote reſemblance to the common cod fiſh, from which it is diſtinguiſhed by its more elongated form, and in having only two dorſal fins inſtead of three. Its food conſiſts of ſmaller fiſhes, worms, crabs and other ſimilar marine productions. In the months of February, March, and April, or even as late as May, it is in ſeaſon for the table; in June it viſits the ſhores to depoſit its ſpawn, and is not in perfection after that time till the enſuing ſpring. The prevalent colour is whitiſh, with the back pale-browniſh. The head is large, and obtuſe; eyes with black pupil and white iris; mouth large; tongue white and thin; body round, and covered with very thin ſcales; fins (except the anal, which is cinereous,) blackiſh, edged with whitiſh, and a black ſpot towards the end of the dorſal fins. The ling grows to the length of ſix or ſeven feet, and is taken in abundance in the north, where it is cured with ſalt, and forms an article of exportation to the more ſouthern parts of Europe, which the ling does not inhabit.

Albidus. Chin with a cirrus; ventral fins long, and bifid. Brünn.

A ſpecies about four inches in length, of a whitiſh colour, ſoft, oblong, and ſlightly compreſſed. The head is pale ſanguineous, above flattiſh, with the ſides compreſſed, and two ſpines behind the eyes. The lower jaw ſhorter, with ſeven punctures beneath each ſide; teeth ſmall, ſharp, and crowded; eyes large with the iris white; lateral line ſtraight; firſt dorſal fin ſmall and blackiſh at the tip; hinder whitiſh, ſpotted with black, the edge and hind part black; anal whitiſh, the poſterior part black; tail rounded and blackiſh. A native of the Mediterranean.

Tau. Bearded; gill-covers three-ſpined; firſt dorſal fin with three rays. Gmel. *Gadus tau; cirris plurimis*, Bloch.

Deſcribed by Dr. Garden as a native of Carolina, and where, according to that obſerver of nature, it is called the toad-fiſh. The body is ſmooth and mucous, above brown, beneath whitiſh; back and fins ſpotted with white, and covered with ſoft, thin, very ſmall, brown ſcales of a rounded form, and edged with white. The head is large and broad; the eyes vertical and large, with the pupil black and iris golden; and on each ſide a double row of ſmall tubercles: between them and the nape a cavity and tranſverſe yellow ſtreak; palate each ſide with a double row of teeth, upper jaw with many, lower only two rows of ſharp uneven teeth; cirri numerous, on the lower jaw only, and diſpoſed in a ſemilunar manner. Gill-covers of two pieces, the membrane large and looſe. The pectoral and ventral fins are pointed,

the

the firſt ray of the poſterior one ſtrong, rigid, and very long. Tail rounded with the rays forked.

Lota. Bearded; jaws equal. Linn. *Silurus cirro in mento unico*, Art. *Botlatriæ, Triſeus*, Salvian. *Leta*, Rondel. *Burbot*, Donov. Brit. Fiſhes.

The burbot inhabits freſh waters in many parts of Europe and Siberia; feeds on ſmaller fiſhes, and grows to the length of two, or even three feet. As an article of food the fleſh is eſteemed delicious. The head of the burbot is large, and rather broad; the eyes ſmall, with blueiſh pupil, and yellow iris; mouth large; jaws with ſeven rows of ſharp teeth. The lower jaw has a ſingle beard, the noſe two; the tongue, and alſo the gill-membrane broad; lateral line ſtraight; dorſal and anal fins long and narrow; and the vent in the middle of the belly.

Mustela. Five beards; firſt dorſal fin obſolete. Gmel. *Five-bearded cod*, Donov. Brit. Fiſhes.

The greateſt length of this ſpecies is mentioned as nineteen inches, and it rarely attains to near that ſize. It feeds on crabs, worms, and ſmall teſtaceous animals, and though not apparently common inhabits moſt of the European ſhores. The colour of this fiſh is olive, or olivaceous on the back and whitiſh beneath, with the fins pale brown, except the pectoral, which are tinged with yellowiſh, and the ventral, which are white at the baſe, and towards the tip roſy. The firſt dorſal fin conſiſts of one ſmall diſtinct ray, and many very obſolete; the ſecond of forty-nine rays; the pectoral of fourteen; ventral ſix; and tail of twenty-four.

Tricirratus. Three beards; firſt dorſal fin obſolete; body ſpotted. Donov. Brit. Fiſhes. *Gadus muſtela β*, Gmel. *Muſtella vulgaris*, Rondel. *Sea loche*, Ceſtriæ. *Whiſtle fiſh*, Cornubiæ, Will. *Rockling*, Jago. *Three-bearded cod*, Penn.

Bloch and Gmelin have followed Willughby in making this a mere variety of the Gadus muſtela, or five-bearded cod; an idea certainly founded in error, the two fiſhes exhibiting characters ſo entirely diſtinct that it is impoſſible they can be of the ſame ſpecies. This ſubject is diſcuſſed, and the point as it is preſumed determined, in a ſatisfactory manner from an attentive compariſon of the two fiſhes in diſpute in "Donovan's Hiſtory of Britiſh Fiſhes." It is there obſerved that the number of beards or cirri in the ſpotted kind, or rockling, never exceed three, nor is the number of thoſe on the true muſtela ever leſs than five. This alone would be in our opinion ſufficiently demonſtrative of a ſpecific difference, but they are furthermore diſtinguiſhed by other peculiarities no leſs deciſive. There is, for inſtance, a diſſimilarity in the form, and alſo in colour, the five-bearded cod being thicker in proportion to its length, and with the colour above olivaceous, beneath whitiſh; while on the contrary a general hue of orange prevails in the other, and this in a remarkable degree on the abdomen, the head, and ventral fins. The body of the latter is alſo ſpotted in an elegant and conſpicuous manner with fuſcous, no trace of which is perceptible in G. muſtela. For theſe and other reaſons the author of the above mentioned work deſcribed the two kinds as diſtinct, and aſſigned the hitherto ſuppoſed variety of muſtela the following new ſpecific character under the title of *Gadus tricirratus*; cirris tribus, pinna dorſali priore exſoleta, corpore maculato.

The three-bearded cod, or rockling, appears from our own reſearches to be moſt common on the rocky ſhores of the weſtern counties of Britain. Its length is from twelve to eighteen inches. The firſt ray of the anterior dorſal fin is ſmall, yet diſtinct, from the reſt which are minute and numerous. The ſecond dorſal fin conſiſts of fifty-four rays; pectoral fin twenty; ventral fins fleſhy, with the ſecond ray longeſt; anal fin with forty-ſix rays, and the tail twenty-four.

Dr. Wallbaum deſcribes another fiſh (a native of Ruſſia) as a variety of muſtela under the name of *ruſſicus γ cirro unico*. Gmelin alſo ſeems to doubt whether the ſpecies Mediterraneus deſcribed by Linnæus from the Muſ. Ad. Fr. and referred by that writer to the ſection with only one dorſal fin, may not be another variety of the ſame fiſh.

Cimbrius. Cirri four; firſt dorſal fin obſolete, the firſt ray ſpear-ſhaped. Gmel. *Le Cimbre*, Boſc. *Cimbrian gadus*.

Deſcribed as a native of the Northern and Atlantic ſeas, and as bearing a cloſe affinity with the ſpecies muſtela, from which it is ſaid to differ chiefly in having the firſt ray of the anterior dorſal fin divided at the tip in the form of the letter T, or rather in two filaments diſpoſed horizontally. There is a ſingle beard on the upper, and another on the lower lip, beſides two over the noſtrils.

** * * Dorſal fin only one.*

Mediterraneus. Upper jaw with two cirri; lower with one. Linn.

Native of the Mediterranean. Lacépede refers it to the Blennius genus, as there are only two rays in the ventral fins.

Brosme. Lower jaw longeſt; tail round, and with the dorſal and anal fin edged with white; ventral fins fleſhy with five cirri. Donov. Brit. Fiſhes. *Gadus Broſme*; mouth bearded; tail oval and pointed. Gmel. *Broſme*, Ström. *Torſk*, Penn.

So much obſcurity has hitherto prevailed over the hiſtory of this curious fiſh, that we ſhall be readily excuſed by the curious reader for entering on this ſubject at ſome length. "The torſk of the Norwegians, Swedes, and Danes (as we have before obſerved in another place) is a very different fiſh from that known in Scotland under the ſame name; a circumſtance that has given riſe to much miſunderſtanding among Engliſh writers reſpecting thoſe two fiſhes. The torſk, or dorſk of the north of Europe, with the exception of Scotland only, is the gadus callarias of Linnæus, a fiſh diſtinguiſhed in a particular manner from the Scotch torſk, by having three fins on the back as we find in our common cod-fiſh and haddock, while the latter is furniſhed with only one dorſal fin: they are alſo materially diſtinct in other reſpects; but theſe are the moſt deciſive and unerring characters that prevail in thoſe two ſpecies.

"The ſame name being common to both thoſe fiſhes in different countries, it was long ſuppoſed, and admitted without farther inveſtigation, that they muſt be of the ſame ſpecies. Pennant was led into this error through that circumſtance: he had learnt that there exiſted a fiſh called the torſk, in the Orkneys, and northern parts of Scotland, and not having ſeen it, concluded it to be of the ſame kind as Linnæus deſcribes under that name in his Fauna Suecica. At a ſubſequent period this miſtake was corrected on the information of Mr. Low, who ſent Mr. Pennant the deſcription and drawing from which the plate was engraven, that appears in the laſt edition of the Britiſh Zoology. Mr. Low was enabled, from his own immediate obſervations, to determine, that the torſk of the Swedes is not the torſk of the Scotch, which renders his account not a little intereſting. The torſk it ſeems, from his account, or as it is called in the Shetlands *tuſk* and *briſmak* (perhaps corrupted from broſme, its Norwegian name) is a northern fiſh, which as yet has not been diſcovered lower to the ſouthward than the Orkneys, and is even there rather ſcarce. In the ſeas about Shetland it ſwarms, and forms either dried or ſalted and packed in barrels a conſiderable article of commerce.

"Ström, a Norwegian clergyman, in his hiſtory of Sondmör, ſpeaks to the ſame effect; he informs us in the north it is called broſme, and being found in great plenty in the ſeas adjacent to Sondmör, there conſtitutes an article of extenſive trade either ſalted, and barrelled, or dried. His ſpecific deſcription of broſme is in Latin gadus monopterygius, ore cirroſo, cauda ovali acuta; and a figure of the fiſh, very well agreeing with this deſcription, is given in the miſcellaneous plate that accompanies the firſt volume.

"There are three different varieties of the Daniſh torſk, in the works of Aſcanius, all which agree with the Linnæan deſcription of gadus callarias. According to Aſcanius all theſe are well known to the Daniſh fiſhermen by the name of torſk, and to the Germans by that of dorſk; they are taken in abundance in the ſea between the iſland of Bornholm, and the north of Bergen, in the Categat, and the Baltic. This writer alſo figures, and deſcribes the broſme (Ic. pl. 17.) in a manner ſo far correct at leaſt as to leave no doubt of its being the ſame as the torſk of Scotland; the latter ſpecies he obſerves connects the gadus with the blennius genus, and is, from its reſemblance to the blenny, called broſme by the fiſhermen: that being the name by which the blenny is diſtinguiſhed amongſt them. We have alſo the authority of Bloch to ſhew, that the gadus callarias is the torſk of the Baltic, and the broſme a different fiſh.

"The reſult of theſe remarks will be ſufficient to prove that the torſk of Scotland agrees in no reſpect, except in name, with the torſk of the other northern parts of Europe, and that the Scotch torſk is beyond doubt the broſme of thoſe countries." *Donov. Brit. Fiſhes.*

In addition to the above extracts the following more general obſervations may with propriety be ſelected.

There can be no diſpute that much of the ambiguity, prevalent in regard to this fiſh, may be traced to the very ſimple cauſe of having been ſometimes deſcribed by authors from the dried inſtead of recent ſtate, as in this caſe it certainly does exhibit a very remarkable difference; a fact we have ourſelves obſerved in endeavouring to preſerve an example of the fiſh which we had an opportunity of inveſtigating in its perfect condition, and indeed poſſeſs at this time. This alteration may be explained with little difficulty: the fins and tail, when the fiſh is alive, or recent, are inveſted with ſkin of ſuch a fleſhy nature as to conceal in a great meaſure the number, and even ſituation of the rays that lie within; but in the proceſs of drying this fleſhy ſkin ſhrinks ſo materially as to leave the rays almoſt bare. The tail, thus diveſted of its fleſhineſs, inſtead of retaining its rounded figure as in the living fiſh, aſſumes the more pointed form of the ſkeleton of the tail, for the central rays are in reality longer than the reſt, though they appear ſo only in a very ſlight degree in the recent ſtate. From a due conſideration of this circumſtance we may eaſily reconcile the two characters "cauda ovali acuta," and "cauda rotundata" which have been aſcribed to the torſk, the former being its appearance in the dried, and the other in its recent ſtate. Gmelin adopts the firſt of theſe, and the conſequence has been that in the Engliſh tranſlation of the Syſtema Naturæ, the Scotch torſk is erroneouſly admitted as a ſpecies diſtinct from the gadus broſme, under the name of Scoticus.

Although the broſme or Scotch torſk ſwarms in the north ſeas, it is ſcarcely ever ſeen more to the ſouthward of Britain than Caithneſs in Scotland, and even there very ſeldom. It is ſometimes brought from Shetland to London for ſale with other ſalt-fiſh. In this ſtate it is eaſily diſtinguiſhed by its ſingle dorſal fin which extends from within a ſhort diſtance of the head to the baſe of the tail.

The length of this fiſh is about twenty-five inches; the colour of the body above pale greyiſh, teſtaceous, beneath white: the dorſal, anal, and caudal fin or tail of the ſame colour as the upper part of the body, very prettily ſpeckled with white, and blueiſh, towards the margin blotched with purple, and a fillet of white forming the extreme border. The pectoral fins were fine yellow, and the ventral reddiſh with the tips duſky.

GADWALL, in *Ornithology*, called alſo the *grey*, a ſpecies of the anas, or duck tribe, diſtinguiſhed ſpecifically by having the wing-ſpot rufous, black and white. The bird is about nineteen inches in length, with the bill flat, and of a black colour; the legs tawny; rump black; back brown with pale tranſverſe undulations, and the breaſt and belly grey varied with white. It is a native of northern Aſia and Europe, and ſometimes viſits our coaſts in ſevere winters. The gadwall is anas ſtrepera of Gmelin. Donov. Br. Birds, &c. See DUCK.

GÆA, in *Ancient Geography*, a town of Arabia Felix, placed by Ptolemy in the interior of the country, and called by Ammianus Marcellinus Geapolis.

GÆELÆUM, *earth-oil*, in *Natural Hiſtory*, a name given by ſome of the old writers to the petroleum, or, as we uſually call it, oil of petre.

GAEL, or *Southern Celts*, formed the earlieſt population of Great Britain; and were called "Guydels" by the Welch, who regard them as their predeceſſors, and who remark, that the moſt ancient names, even in Wales, are Guydelic, not Cumraig or Welch. Theſe Gael appear to have proceeded from the neareſt ſhores of France and Flanders. The original Gaelic inhabitants ſeem to have almoſt entirely evacuated the country, and to have retired to Ireland, which was alſo originally peopled from Gaul. There, and in the Highlands of Scotland, to which a Gaelic colony paſſed from Ireland, the Gaelic dialect of the Celtic language ſtill exiſts.

GAELIC, or ERSE. This is the name of that dialect of the ancient Celtic language, which is ſpoken in the Highlands of Scotland. According to the opinion of antiquarians, the Celtic, at the time of the Roman invaſion, was univerſally ſpoken all over the weſt of Europe. Though it is divided into a variety of dialects, yet they all bear the cleareſt internal proofs of their being deſcended from one common origin. The moſt remarkable dialects of the Celtic, ſtill in exiſtence, are the Gaëlic, the Welch, the Manks, the Iriſh, and the Corniſh, the laſt of which appears to be nearly loſt. To this liſt may juſtly be added the dialect, which is ſpoken by the natives of the province of Bretagne in France. The Gaëlic, which, from a variety of cauſes, is preſerved in a conſiderable degree of its original purity, is bold, expreſſive, and copious. It derives no aſſiſtance from the languages either of Greece or Rome, from which it differs in its ſtructure and formation. Having its affixes and prefixes, it greatly reſembles the Hebrew, particularly in the inflexions of its nouns and verbs. Like the modern French it only knows two genders, the maſculine and feminine. If ever the Gaelic poſſeſſed an alphabet peculiar to itſelf, no traces whatever of it now remain. Nor can it boaſt of any original literary production, unleſs the poems of Oſſian be allowed to form an exception.

Of late the ſcriptures and other religious books have been very correctly tranſlated into Gaëlic, from which the inhabitants of the Highlands derive conſiderable advantages. Notwithſtanding every diſcouragement and oppoſition on the part of the Highland proprietors, who conſider, perhaps not without reaſon, the exiſtence of the Gaëlic as operating againſt the general improvement of that part of the kingdom, it is ſo far from being on the decline, that it has actually, within

within the laſt century, in many places, encroached on the Engliſh. Such as would wiſh to arrive at accuracy in topographical knowledge, would do well to ſtudy Gaëlic, as more than two-thirds of the names of places in the united kingdom are evidently of Celtic extraction. Some months ago a chapel has been opened in London, where divine worſhip is performed in Gaëlic according to the forms of the church of Scotland.

GÆRTNER, Joseph, in *Biography*, a botaniſt eminently diſtinguiſhed for his attention to fruits and ſeeds, with a view to the more certain diſcrimination of the genera of plants, was born at Calw in the duchy of Wirtemberg, March 12, 1732. His father, phyſician to the duke of Wirtemberg, and his mother, whoſe maiden name was Wagner, both died in his early youth. He was at firſt deſtined by his ſurviving relations for the church, and received the earlieſt parts of his education at Tübingen and Stutgard; but not proving ſuitable to the profeſſion which had been choſen for him, he was directed, with no better ſucceſs, to the law. Having had an early bias towards the ſtudy of natural hiſtory, he reſorted to phyſic, as moſt congenial to his diſpoſition, and removed to the celebrated univerſity of Gottingen in the 19th year of his age. Here the lectures of the great Haller and others confirmed and inſtructed him in the darling objects of his purſuit, anatomy, phyſiology, and botany, and ultimately decided him to devote himſelf to theſe ſtudies, rather for his own information and amuſement, than as a means of advancement in the practice of phyſic. Thus Gærtner became a profeſſed naturaliſt, and undertook a tour through Italy, France, and England, in the purſuit of knowledge in this line of ſtudy. He, however, took the degree of doctor of medicine on returning to his own country, and publiſhed an inaugural diſſertation on the urinary ſecretion, after which he devoted two years to the ſtudy of mathematics, optics, and mechanics, conſtructing with his own hands a teleſcope, as well as a common and ſolar microſcope. In the ſummer of 1759, he attended a courſe of botanical lectures at Leyden under the celebrated Adrian Van Royen, and formed an intimate friendſhip with David Van Royen, the nephew, and afterwards ſucceſſor, of the former. He had for ſome time acquired the uſe of the pencil, in which he eminently excelled, and which ſubſequently proved of the greateſt uſe to him in enabling him to draw the beautiful and accurate figures of the books he publiſhed. Having beſtowed great attention upon the obſcurer tribes of marine animals and plants, particularly with a view to the mode of propagation of the latter, as well as of other cryptogamic vegetables, he reviſited England, and ſpent ſome time here, as well in ſcrutinizing the productions of our extenſive and varied coaſts, as in converſing with thoſe able naturaliſts Ellis, Collinſon, Baker, and others, who were aſſiduouſly engaged in ſimilar purſuits. He communicated a paper to the Royal Society on the polype called *Urtica marina*, and the *Actinia* of Linnæus, comprehending deſcriptions and figures of ſeveral ſpecies, which is printed in the 52d volume of the Philoſophical Tranſactions; and he prepared ſeveral eſſays on the anatomy of fiſhes, and other obſcure matters of animal and vegetable phyſiology, part of which only has hitherto been made public. Soon afterwards Dr. Gærtner became a member of the Royal Society of London, and of the Imperial Academy of Sciences at Peterſburg. In 1768, he was inſtituted profeſſor of botany and natural hiſtory in the place laſt mentioned, and about a year afterwards he began to plan, and prepare materials for, the great work on which his eminent reputation reſts, the object of which was the illuſtration of fruits and ſeeds, for the purpoſes above mentioned. His ſituation at Peterſburg however ſeems not to have ſuited either his health or diſpoſition. After having performed a journey into the Ukraine, in which he collected many new or obſcure plants, he reſigned his profeſſorſhip at the end of two years, ſteadily refuſing the penſion ordinarily attached to it, and retired in the autumn of 1770 to his native town, where he married a lady of the name of Mutſhelin, and gave himſelf up to domeſtic and ſcientific tranquillity. At the end of eight years he found it neceſſary, for the perfection of his intended work, to reviſit ſome of the ſeats of ſcience in which he had formerly ſtudied, in order to re-examine ſeveral botanical collections, and to converſe again with perſons devoted to ſimilar inquiries with his own. Above all he was anxious to profit by the diſcoveries of the diſtinguiſhed voyagers Banks and Solander, who received him with open arms on his arrival at London in 1778, and, with the liberality which ever diſtinguiſhed their characters, freely laid before him all their acquiſitions, and aſſiſted him with their own obſervations and diſcoveries. A new genus was dedicated to Gærtner by his illuſtrious friends in their manuſcripts; but this being his own *ſphenoclea*, has been ſuperſeded by another and a finer plant; ſee Gærtnera. He viſited Thunberg in his return through Amſterdam, that diſtinguiſhed botaniſt and traveller being then lately arrived from Japan; nor were the acquiſitions of Gærtner leſs conſiderable from this quarter. He further enriched himſelf from the treaſures at Leyden, laid open to him by his old friend Van Royen; and arrived at home laden with ſpoils, deſtined to enrich his intended publication.

Here however his labours and his darling purſuits were interrupted by a ſevere diſorder in his eyes, which for many months threatened total blindneſs; nor was it till after an intermiſſion of four or five years that he was able to reſume his ſtudies.

At length he gave to the public the firſt volume of his long-expected work, *de fructibus et ſeminibus plantarum*, printed at Stutgard in 1788, and containing the eſſential generic characters, with particular deſcriptions of the fruit, of 500 genera, illuſtrated by figures of each, admirably drawn by himſelf, and neatly engraved in 79 quarto plates; a long anatomical and phyſiological introduction is prefixed, in which he defines and explains the nature of the parts of fructification, eſpecially of the fruit and ſeed. In this eſſay he denies the exiſtence of real flowers, and conſequently of proper ſeeds, in *Fungi*, and other cryptogamic vegetables, in which Hedwig and others conceive they had detected the organs of impregnation as well as real ſeeds. Gærtner conſiders the latter as *gemmæ* or buds, and not ſeeds produced by ſexual impregnation. He even denies the celebrated Hedwigian theory of moſſes. He changes the name of *germen*, applied by Linnæus to the rudiments of the fruit in old plants, to the old and erroneous term *ovarium*. (See Germen.) In the detail of his work he often corrects the great Swediſh naturaliſt, with more or leſs juſtice, but not always with candour, and changes his names frequently for the worſe. In ſynonyms he is not always exact, copying them, as it appears, from errors of the preſs occaſionally tranſcribed from other authors, without turning to the books quoted.

In the definition and anatomical elucidation of the parts of the ſeed, Gærtner is truly excellent, though it has been doubted of late whether what he terms *vitellus* has any real exiſtence diſtinct from the cotyledons, and Dr. Smith is of opinion that he has proved the contrary. (See Tranſ. of the Linnæan Soc. vol. 9th 204.) In his deciſions in difficult caſes concerning the eſtabliſhment of particular genera, Gærtner, like all botaniſts whoſe fixed attention is bent upon

upon one part of the fructification in preference to the reſt, ſometimes gives too much importance to that part, loſing ſight of the great maxim, that "the genus ſhould give the character, not the character the genus." Notwithſtanding theſe ſlight defects, the work of Gærtner is one that marks an era in botanical ſcience, not only directing, but even forcing the attention of botaniſts, to parts which the Linnæan ſchool had too much neglected, but which can never in future be overlooked. The ſecond volume of this immortal work appeared in 1791, illuſtrating 500 more genera, on the ſame plan with the former, in 101 plates, in which the compound flowers are treated with peculiar care and ſucceſs. The preface of this volume is dated April 6, 1791, but little more than three months before the death of the author, which happened on the fourteenth of July 1791, in the 60th year of his age. He is ſaid, though ſtruggling for ſome time preceding with debility and diſeaſe, to have finiſhed a deſcription and drawing of the *Halleria lucida* but the evening before his departure. He left one ſon, to whom he gave an excellent education, and who has proved worthy of his diſtinguiſhed father, in publiſhing his inedited works, and continuing with ſucceſs the ſame inquiries. Deleuze in Sims and Konig's Ar- ls of Botany, v. 1. 73.

GÆRTNERA, in *Botany*, in honour of Joſeph Gærtner, M. D. (See the laſt article.) Schreb. 290. Willd. Sp. Pl. v. 2. 550. (Hiptage; Gærtn. v. 2. 169. t. 116. Molina; Cavan. Monad. diſſ. 9. 435. t. 263. Lamarck Illuſtr. t. 349.) Claſs and order, *Decandria Monogynia*. Nat. Ord. *Tribilatæ*, Linn. *Malpighiæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, oblong, obtuſe, ſpreading, nearly equal ſegments, permanent. *Cor.* Petals five, roundiſh, large, flattiſh, nearly equal, ſpreading, with very ſhort claws; their margin jagged and fringed. *Stam.* Filaments ten, thread-ſhaped, ſlightly united at their baſe; nine of them more ſlender, nearly erect, ſhorter than the corolla; the tenth thicker, the length of the adjoining petal, incurved at the top; anthers oblong, quadrangular; nine of equal ſize; the tenth, on the longeſt filament, rather the largeſt. *Piſt.* Germen ſuperior, ſmall, three-toothed; ſtyle thread-ſhaped, lateral, incurved, the length of the longeſt ſtamen, permanent; ſtigma acute. *Peric.* Capſule woody, of one cell, without valves, roundiſh, crowned with four lanceolate, obtuſe, unequal, coriaceous wings, of which the largeſt is erect, the two leſſer ſpreading, and the leaſt aſcending. *Seed* ſolitary, roundiſh, deſtitute of albumen.

Eſſ. Ch. Calyx in five deep diviſions. Petals five, fringed and jagged. One ſtamen longer than the reſt. Capſule with four unequal wings, of one cell, without valves.

1. G. *racemoſa*. Vahl Symb. faſc. 3. 58. Roxb. Coromand. v. 1. 19. t. 18. Andr. Repoſ. t. 600. (Banniſteria benghalenſis; Linn. Sp. Pl. 611. B. tetraptera; Sonnerat. Ind. Orient. v. 2. 238. t. 135. Sida Pou; Rheede Hort. Mal. v. 6. 109. t. 59.)—Native of the Eaſt Indies, and the only ſpecies known. The *ſtem* is woody and climbing. *Leaves* oppoſite, ſtalked, laurel-like, elliptic-oblong, ſmooth and entire. *Cluſter* terminal, erect, of numerous elegant *flowers*, ſomewhat reſembling thoſe of the horſe cheſnut, their petals being white, and one of them eſpecially broadly marked with yellow. This ſhrub flowers in India during the cool and rainy ſeaſon, and, according to Dr. Roxburgh, is cultivated throughout the coaſt of Coromandel, on account of the beauty and fragrance of its bloſſoms. That gentleman ſent a plant to the late lady Amelia Hume, in whoſe garden it flowered in the ſpring of 1810, for the firſt time probably in Europe.

GÆSATI, in *Ancient Geography*, a warlike people among the Gauls, who are deſcribed by Polybius as ready to fight for any nation which would pay them; accordingly their name denotes "hirelings."

GÆSUM, or GÆSUS, a river of Aſia Minor, which ran between Miletus and Prienè, and diſcharged itſelf into a marſh, and from thence into the ſea.

GÆTA, in *Geography*, a ſea-port town of Naples, in the province of Lavora, anciently "Cajeta," ſo called, according to Virgil, from Æneas's nurſe. It is ſituated on the point of a promontory, and joined to the continent by a narrow iſthmus northward, the reſt being ſurrounded by the ſea, ſo that it forms a peninſula. Ferdinand II. of Aragon, appriſed of its importance, fortified it with good walls and a citadel; and to theſe other fortifications have been ſince added, which, together with its ſituation on a rock, renders it very difficult of acceſs. The ſea flows into its moats, which are both broad and deep, ſo that its entrance is defended by armed veſſels, and its citadel, built on an eminence, commands the city. Its harbour, anciently repaired by Antoninus Pius, is good and ſecure, and its gulf abounds with fiſh particularly ſturgeons, of which the cavear is made. The town is not large, the ſtreets are narrow, and the houſes are built on porticoes.

It is the ſee of a biſhop, ſuffragan of Capua, which was transferred thither after the Saracens had ruined Nola in the year 956. Its vicinity is pleaſant, and the ſoil very fertile. 40 miles N.W of Naples. N. lat. 41° 15'. E. long. 13° 28'.

GÆTANO, ST., a town of New Navarre; 60 miles S. of Caſa Grande.

GÆTULIA, in *Ancient Geography*, a country of Africa, the ſituation and limits of which are not accurately aſcertained; and, indeed, they do not ſeem to have been always the ſame. In Pliny's time, the Gætulians poſſeſſed a conſiderable part, at leaſt, of Tingitania. Feſtus Avienus fixed their eaſtern boundary not far from the weſtern confines of Marmarica. Strabo intimates that the Gætulians formed a large nation, taking up a conſiderable part of Libya Interior, and poſſeſſing ſome territories in the neighbourhood of the Syrtes. Pliny maintains that Gætulia was terminated on the ſouth by the river Nigris, called by Ptolemy Niger, which, according to him, ſeparated it from Ethiopia. The northern limits of this undefined country ſeem to have been contiguous to, and frequently coinciding with, the ſouthern parts of Numidia and the Mauritaniæ, and it could not have extended to any great diſtance in the Sahara. Dr. Shaw (Travels) intimates, that the proper Gætulia did not reach farther to the eaſt than the meridian of Siga, provided that Tackumbreet be the ancient Siga, as he imagines; ſince he affirms that the Mælanogætuli and Garamantes occupied the tract behind Numidia, Africa Propria, and the Regio Syrtica, from that meridian to Cyrenaica. In another place, however, he fixes ſome Gætulian tribes in the remoteſt part of the diſtrict of Zaab, and meridian of Conſtantina, above ſix degrees more to the eaſtward than Siga. We may here obſerve that Guzula, or Gezula, a province of the kingdom of Morocco, at the foot of Mount Atlas, has preſerved ſome traces of the ancient Gætulia. As the Gætulians, before the time of Jugurtha, led their flocks from paſture to paſture, living generally in tents, without any fixed habitation, their country will not preſent to view many towns. Philoſtratus ſays, that they inhabited the interior part of mount Abinna, or Abyla; and conſequently by intermixing them with the Mauruſii, allows ſome of them to have dwelt in towns. Pliny alſo intimates, that they poſſeſſed in his time great part of Maſſæſylia; and Apuleius aſſigns them ſome diſtricts at leaſt of Numidia Propria; but Pliny and Ptolemy

render it indiſputable, when they mention the cities of Autolala and Talubath, as appertaining to the Gætulians. The principal tribes of Proper Gætulia were the Baniuræ, Darræ, and Autololes. The Baniuræ, probably, bordered upon Tingitania, as the Darræ did upon the Ethiopians, called Perorſi, and the Pharuſii. The Autololes ſeem to have been much the moſt powerful, and to have ſpread themſelves over that part of Tingitania bordering on the coaſt of the Atlantic ocean. Their capital city, Autolala, from which they derived their name, ſtood betwixt the Subus and the Salathus, the only two rivers of note except the Gir and the Nigir, that watered Gætulia. As the Sahara roſe near the ſouthern foot of Mount Atlas, this country was without doubt for the moſt part ſandy and deſert; though it was interſperſed with fruitful ſpots. Mount Sagapole, the limit of Gætulia on the ſide of the Melanogætuli, and containing the ſources of the Subus and Salathus, ſeems to have been the only remarkable mountain in the region we are now deſcribing. The only curioſity worthy of particular notice was the vaſt quantity of the purple-fiſh produced in that part of the Atlantic ocean that waſhed the Gætulian ſhore, with which the rocks on this coaſt were frequently covered.

According to Joſephus and Jerome, Chavilah or Havilah, the ſon of Cuſh, was the father of the Gætulians; and therefore they were called Evilæi or Havilæi. Havilah, or Chavilah, having ſettled in Arabia Felix, gave to his deſcendants the name of Chauletæi and Chauleſii; and hence it has been inferred that Gætulia was firſt peopled from Arabia Felix. The firſt Gætulians, according to the Punic hiſtorians, were ſome of the moſt ancient inhabitants of Africa, extremely rude and barbarous, without any form of government, laws, or manners. They lived upon the fleſh of wild beaſts, eating upon the ground, after the manner of cattle; they roved about the country, lodging wherever the night ſurpriſed them. Some authors, however, believe, that the Gætulians, though rude and barbarous, at leaſt near the Roman times, were under the direction of certain phyllarchs, or heads of Kabyles, as their poſterity are at this day. Their peculiar laws and cuſtoms are now unknown. Their religion probably reſembled that of their neighbours, or of their progenitors, the ancient Arabs; and as they were partly deſcended from the Perſians, or intermixed with them, they might profeſs the Magian religion. Their language muſt undoubtedly have borne a near reſemblance to the ancient Arabic, and other oriental tongues. In the times of Herodotus and Scylax the Gætulians muſt have been an obſcure people, as thoſe writers take no notice of them. The firſt authors that mention them were probably ſome of thoſe old hiſtorians, whoſe works furniſhed Livy with information concerning them; and from whom we learn, that a corps of that people ſerved under Hannibal in the ſecond Punic war. Salluſt informs us, that Jugurtha inſtructed the Gætulians in military diſcipline; and they ſerved that prince more effectually by plundering the allies of the Romans, than by their bravery in time of action; for the army he had raiſed and diſciplined in Gætulia was eaſily routed by Marius under Cirta. That part of Gætulia which was under the dominion of Juba revolted to Julius Cæſar; but when that with Numidia was reduced into a Roman province, we cannot poſitively affirm; eſpecially ſince Auguſtus beſtowed a part of Gætulia, probably this, with the Mauritaniæ, on the younger Juba, as an equivalent for Numidia, his father's kingdom, which, ſays Dio, had before been converted into a province. About the year of Rome 759, the Gætulians rebelled againſt king Juba, maſſacring all the Romans ſettled in his dominions, and committing moſt dreadful ravages in all the provinces ſubject to him. Dio aſcribes this defection to the reſentment of the Gætulians, who were extremely incenſed againſt the Romans for impoſing a prince upon them, and not permitting them to live under the Roman government. However, Cornelius Coſſus ſo completely defeated them, that they were obliged to ſubmit upon the terms which he thought fit to preſcribe. This was eſteemed at Rome ſo ſignal an exploit, that triumphal honours were decreed to him, and he was allowed to aſſume the cognomen Gætulicus. Notwithſtanding this diſaſter, the Gætulians recovered themſelves to ſuch a degree, that in the elder Pliny's time they had ſettlements in Numidia and Tingitania, as we may infer from that author and Philoſtratus.

GÆTULIANS. See GETULIA, ſupra.

GÆTULIANS, *Black*. See MELANOGÆTULI and NIGRITÆ.

GAFERAID, in *Geography*, a town of Aſiatic Turkey, in Caramania; 32 miles S. E. of Cogni.

GAFET, in the *Materia Medica of the Arabians*, a name given by Avicenna and others to the ſarcocolla of the Greeks.

GAFF, in *Sea Language*, a ſort of boom or pole uſed to extend the upper edge of the mizen; the foremoſt or inner extremity of it is furniſhed with two cheeks, forming a ſemi-circle, which incloſe the after part of the maſt, ſo as to confine the gaff cloſe to its reſpective maſt whilſt the ſail is hoiſting or lowering.

GAFFS. See GABLOCKS.

GAFILE, in *Geography*, a town of Sweden, in the lapmark of Aſele, on a river of the ſame name; 25 miles E.S.E. of Aſele.

GAFOLD-LAND, or GAFUL-*land*, *terra ſenſualis*, in our *Old Writers*, land liable to taxes, and rented or let for rent.

GAFORUS, or GAFURIUS, See FRANCHINUS.

GAFSA, in *Geography*, a town of Africa, in Biledulgerid, anciently called *Capſa*, which ſee.

GAG, in *Geography*, one of the iſlands in the oriental Archipelago, adjoining to the main land of Papua or New Guinea, which ſee.

GAGÆ, in *Ancient Geography*, a town of Aſia, in Lycia.—Alſo, a river of Aſia, in Lycia, which furniſhed the ſtone called "Gagates." Pliny. Dioſcorides.

GAGANIGURRA, in *Geography*, a town of Hindooſtan, in Baramaul; five miles E. of Caveripatnam.

GAGARAWAD-BAY, a bay on the N. coaſt of the iſland of St. Vincent.

GAGASMIRA, in *Ancient Geography*, a town of India, on this ſide of the Ganges, (Ptolemy); ſuppoſed to be the modern *Agimere*, which ſee.

GAGATES. See JET.

GAGATUN, in *Geography*, a town of Bengal; twenty-five miles E. of Dacca.

GAGE, in our *Ancient Cuſtoms*, ſignifies a pledge, or pawn, given by way of ſecurity.

The word is only properly uſed in ſpeaking of moveables: for immoveables, the term *hypotheca* is uſed.

If the gage periſh, the perſon who received it is not to anſwer for it, but only for extreme negligence, &c.

GAGE is alſo uſed for a challenge to combat.

In which ſenſe it was a pledge, which the accuſer, or challenger, caſt on the ground, and the other took up, as accepting the challenge: this was uſually a glove, gantlet, chaperoon, or the like.

The Grand Cuſtomary mentions *gages pleiges de duel*.

Theſe were gentlemen of the relations or friends of the combatants. If he who had given the *gages pleiges* was overcome, he was to pay a mulct agreed on.

GAGE is only now retained as a ſubſtantive: as a verb, the *g* is changed into *w*; and of *gage* is formed *wage*. As,

to wage law, to wage deliverance, *q. d.* to give ſecurity a thing ſhall be delivered.

If a perſon who has diſtrained be ſued for not having delivered what he had took by diſtreſs, he ſhould wage, or gage, or gager, deliverance; that is, put in ſurety that he will deliver them.

GAGE, *mort, mortuum vadium*, is that which is left in the hands of the proprietor, ſo that he reaps the fruits thereof: in oppoſition to *vif-gage, vivum vadium*, where the fruits or revenues are reaped by the creditor, and reckoned on the foot of the debt, which diminiſhes in proportion thereto. The ſecond acquits or diſcharges itſelf, and as it ſubſiſts, ſurvives the debt, and is therefore called living pledge; the firſt does not.

Pomey alſo uſes mort-gage for the poſſeſſion of any effects, on condition of ſurrendering them up at the good pleaſure of the perſon who gave them. See MORTGAGE.

GAGE, in *Carpentry* and *Joinery*, is an inſtrument for drawing a line on one of the faces of a piece of ſtuff parallel to another, in order to reduce the ſtuff to a breadth or thickneſs.

Its chief uſe is for gaging of tenons true, to fit into mortiſſes; and for gaging ſtuff of an equal thickneſs.

It is made of an oval piece of wood, fitted upon a ſquare ſtick, to ſlide up and down ſtiffly thereon, and with a tooth at the end of a ſtaff, to ſcore, to ſtrike a line upon the ſtaff at any diſtance, according to the diſtance of the oval from it.

GAGE, in the *Sea Language*. When one ſhip is to windward of another, ſhe is ſaid to have the *weather gage* of her.

The ſeamen alſo call trying how much water a ſhip draws *gaging*, or rather *gauging* of her; and it is done thus: They drive a nail into a pike, near the end, and then put down this pike by the rudder, till the nail catch hold under it; for then, as many feet as the pike is under water is the ſhip's gage, or depth of water ſhe draws.

GAGE, among *Letter-founders*, is a piece of box, or other hard wood, variouſly notched; which is uſed to adjuſt the dimenſions, ſlopes, &c. of the different ſorts of letters. There are ſeveral kinds of theſe gages. See FOUNDERY.

GAGE, in *Pneumatics*, is of various ſorts, according to the purpoſes to which it is applied. Thus.

GAGE *of the Air-pump*. The principle upon which the gage of the air-pump is conſtructed is very obvious; we ſhall here briefly deſcribe thoſe that are in common uſe, and refer to the article AIR-*pump* for the mode of their application. The "ſhort barometer gage" is merely the lower part of a barometer or a tube about eight or nine inches in length, filled with mercury, and immerſed with its aperture into a ſmall quantity of mercury contained in a glaſs-veſſel, which forms the ciſtern. This gage is either placed under the receiver upon the principal plate of the pump, or it is placed under a ſeparate ſmall receiver, upon a ſmall auxiliary plate, which is annexed to ſome air-pumps for this purpoſe. As this gage is not equal to a whole barometer, it will not ſhew the very ſmall degree of rarefaction; but its indications will commence when about three-quarters of the air have been removed from the receiver, that is, when the air has been rarefied till its remaining elaſticity is not able to ſupport that column of mercury. This gage has a ſcale of inches and parts of an inch affixed to the tube, which ſhews the preciſe altitude of the mercury in it. The "long barometer gage" is a tube of about thirty-three inches in length, open at both ends, having its lower end immerſed in a ciſtern of quickſilver, which is fixed on the pedeſtal, or lower part of the frame of the pump; the tube itſelf reaching from that place to the height of the plate. The upper aperture of the tube communicates, by means of a braſs tube, with the inſide of the pump. This is, in reality, an empty barometer, which is filled with quickſilver, by withdrawing the air from it through its upper aperture; and if the pump could produce a perfect vacuum, the mercury in this long gage would riſe as high as it does in the common barometer; but as the pump cannot exhauſt ſo far, therefore the difference of altitude between the mercury of the long gage, and that of a common barometer, ſhews the quantity of air that remains in the receiver. This difference of altitude is indicated by a ſcale of inches and parts of inches, which is always affixed to the long barometer gage. As the altitude of the mercury in a common barometer is to its cotemporaneous altitude in this gage, ſo is the whole quantity of air which was in the receiver before the rarefaction to that quantity which has been drawn out of it. The "ſyphon-gage" differs from the ſhort barometer gage merely in this circumſtance; that inſtead of terminating in a little ciſtern, in this gage the tube is bent and riſes upwards with its aperture, which by means of a braſs tube is made to communicate with the inſide of the pump; ſo that the aſcending leg of the tube performs the office of a ciſtern: hence, in rarefying the air, the mercury deſcends from the cloſed end of the tube, and riſes into the aſcending leg; and conſequently the altitude of it in one leg above its altitude in the other leg, which is in reality the ciſtern, ſhews the degree of rarefaction, and this altitude is denoted by an annexed ſcale of inches and parts of inches.

The gages above-mentioned evidently indicate the elaſticity of the fluid, which remains in the receiver of the pump after a certain degree of rarefaction; and it is immaterial whether that elaſtic fluid be air, or vapour of water, or other elaſtic fluid; but there is another gage, which from its ſhape was called the "pear-gage" by its inventor, Mr. Smeaton, and which ſhews (not at the actual time, but after the re-admiſſion of air into the receiver) how much air was left in the receiver in the preceding rarefaction. This pear-gage conſiſts of a glaſs-veſſel A (*Plate* XIV. *Pneumatics*, *fig.* 4.) which has a ſmall projecting orifice B, and at the other end it is extended into a tube cloſed at D; the capacity of this tube is the 100dth part of the capacity of the whole veſſel. This gage is ſuſpended, with its aperture downwards, to the lower end of a ſlip-wire, or a wire which paſſes through a collar of leather, within a glaſs-receiver of the pump, and exactly under it a ſmall cup, containing quickſilver, is placed upon the plate of the pump. When the pump has been worked to the intended degree, the air in the pear-gage is evidently rarefied as much as it is in the receiver. In that ſtate, by lowering the ſlip wire, the pear-gage is let down till its aperture B has reached the bottom of the mercury. This done, the external air is admitted into the receiver; but it cannot be admitted into the pear-gage, becauſe the aperture B of that gage is now immerſed in the quickſilver; but the preſſure of the atmoſphere on the ſurface of the quickſilver forces that fluid into the pear-gage, and fills it up to a certain degree E; then the upper part D E of the gage will contain all the air or vapour which occupied the whole cavity of the gage during the rarefaction. Annexed to the upper part D E of the gage is a divided ſcale, which ſhews what part of the capacity of the whole gage is filled with air, and of courſe it manifeſts the degree to which the rarefaction of the air had been carried. *E. G.* If we find that the part D E of the gage, which is filled with air above the quickſilver, is the 500dth part of the whole, we may conclude, that the air in the receiver had been rarefied 500 times, &c. But between the indications of this and of the preceding gages, there will

will be a very conſiderable difference. When the receiver contains no other fluid beſides air, then the pear-gage and the other gages indicate the ſame degree of rarefaction; but if the receiver contain the vapour of water or of other liquor, then the pear-gage will indicate a much greater degree of rarefaction than the other gages; becauſe the vapour which has elaſticity ſufficient to ſupply the place of air in the receiver, on the re-admiſſion of air, is condenſed into a ſpace much ſmaller than the ſame quantity of rarefied air can be condenſed into; ſo that the pear-gage ſhews the quantity of *air* alone which had been left in the receiver; whereas the other gages ſhew the quantity of elaſtic fluid which is actually remaining in the receiver.

The extraordinary powers of exhauſtion in Mr. Smeaton's air-pump, as they are indicated by his pear-gage, have been conſidered with peculiar attention by Mr. Nairne, F.R.S. He was led to proſecute a ſeries of experiments on this ſubject, by obſerving the remarkable difference between the indications of exhauſtion and rarefaction by this gage, and by the common barometer-gage. Having uſed every poſſible precaution in preparing his different gages, he nevertheleſs found, that, when they are put under a receiver, placed on a leather dreſſed in alum, and ſoaked in oil and tallow, according to his uſual method, and the pump was worked for ten minutes, the quickſilver in the barometer-gage roſe to within one tenth of an inch of the height of the quickſilver in the ſtandard barometer, which was at that time at thirty inches, and indicated that the air had been rarefied only about three hundred times; whereas Mr. Smeaton's pear-gage indicated a degree of exhauſtion equal to ſix thouſand times; the whole of its cavity, on dipping its open end into the cup of quickſilver, and letting in the air, except a ſix thouſandth part, being filled by the quickſilver. The difference of indications by theſe two gages was found much more conſiderable in ſubſequent experiments. Having an opportunity of repeating ſome of theſe experiments before the honourable Henry Cavendiſh, Mr. Smeaton, and others, in April 1776, Mr. Cavendiſh accounted for the obſerved and aſtoniſhing difference, by referring to ſome experiments of his father, lord Charles Cavendiſh, from which it appeared, that water, whenever the preſſure of the atmoſphere on it is diminiſhed to a certain degree, is immediately turned into vapour, and reduced as ſuddenly to water again on reſtoring the preſſure: the degree of preſſure varies according to the temperature of the water; for when the heat is 72° of Fahrenheit's ſcale, it turns into vapour as ſoon as the preſſure is reduced to that of three quarters of an inch of quickſilver, or about one fortieth of the uſual preſſure of the atmoſphere; but when the heat is only 41°, the preſſure muſt be reduced to that of a quarter of an inch of quickſilver, or to one hundred and twentieth of the uſual preſſure, before the water turns into vapour. According to this theory, whenever the air in the receiver is exhauſted to the above-mentioned degree, the moiſture adhering to the different parts of the machine will be converted into an elaſtic vapour, and ſupply the place of the air, which is drawn away by the working of the pump; and the fluid left in the receiver and pear-gage will be chiefly this vapour. When the air is let into the receiver, the vapour within the pear-gage will be reduced to water, and only the real air will remain uncondenſed; and therefore this gage only ſhews how much real air is left in the receiver, and not how much the preſſure or ſpring of the included air is diminiſhed; whereas the barometer-gage ſhews how much the included fluid is diminiſhed, and that equally, whether it conſiſts of air or vapour. In order to aſcertain the truth of this plauſible theory, Mr. Nairne proceeded to free every part of his apparatus as much as poſſible from any adhering moiſture, concluding that by this means he ſhould be able to bring the two gages to an agreement. Inſtead of placing the receiver on leather, as before, he put it on the pump-plate, made as clean and dry as poſſible, and applied a cement round its edge to exclude the outward air. When the pump in this ſtate was worked for ten minutes, the barometer-gage indicated a degree of exhauſtion nearly equal to ſix hundred; and, on letting the air into the receiver, the pear-gage indicated a degree of exhauſtion little more than ſix hundred alſo. In another experiment he put a piece of the oiled leather above mentioned in the receiver, and found, on working the pump, that the barometer-gage indicated a degree of exhauſtion of nearly three hundred, but the pear-gage indicated a degree of exhauſtion not leſs than four thouſand. But on taking out the piece of leather, and repeating the experiments, the two gages agreed, as before. Having thus concluded, in general, that a conſiderable quantity of vapour aroſe from the compound of leather, alum, oil, and tallow, it was his next object to find out from which of theſe ſubſtances the vapour was principally derived. For this purpoſe he ſeparately and ſucceſſively included in the receiver two ounces of tallow, the ſame quantity of oil and alum, and a piece of leather as it comes from the leather-ſellers, weighing a hundred grains: from theſe experiments he found that the elaſtic vapour, which occaſioned ſo great a difference in the teſtimony of the gages, aroſe chiefly from the leather, and very little from the tallow, oil, and alum. In the experiment with the leather, it ſupplied the place of the exhauſted air ſo faſt, that he could not in ten minutes make the barometer-gage indicate a degree of exhauſtion of more than a hundred and fifty-nine; whereas that of the pear-gage was a hundred thouſand. In order to determine whether the difference in the gages was occaſioned by the moiſture of the leather, Mr. Nairne repeated the experiment with a piece of freſh leather, weighing a hundred grains. The pear-gage indicated a rarefaction of a hundred thouſand, and the leather had loſt two grains of its weight; when the ſame piece of leather was ſo thoroughly dried by the fire till it would loſe no more of its weight, and thus reduced to eighty grains, it gained two grains in the experiment, and the pear-gage exhibited a rarefaction only of two hundred and eighty. The leather was afterwards held in the ſteam of hot water till it had regained its former moiſture and weight, and the degree of exhauſtion indicated by the pear-gage was a hundred thouſand, and the loſs of weight, two grains, as before. In the firſt of theſe experiments, the degree of rarefaction indicated by the barometer-gage was a hundred and thirty-four; in the ſecond, two hundred and ſixty-eight; and in the third, one hundred and forty-ſeven. The effect of the vapour ariſing from ſmall quantities of different fluids, and from other ſubſtances containing moiſture, was tried in a variety of inſtances; and having found that the ſmall quantity of moiſture which exhaled from the ſubſtances under the receiver, prevented the pump from exhauſting to a conſiderable degree, Mr. Nairne ſuſpected that whenever wet leather had been uſed to connect the receiver with the plate, there muſt have ariſen ſo great a quantity of vapour as to have prevented the degree of exhauſtion from being near ſo great as in other inſtances. This led him to another ſet of experiments, in order to aſcertain this fact. Having firſt placed the receiver on the pump-plate, made clean and dry, with only a little oil poured round the outſide edge of it, both gages agreed in indicating a rarefaction of ſix hundred, as before: but when the receiver was ſet on leather that had been ſoaked for two days in water, the rarefaction indicated by the barometer-gage

was

was uniformly fifty-one in three different trials; but the pear-gage exhibited firſt ſixteen thouſand, in the ſecond inſtance fifteen hundred, and in the third one thouſand: when the receiver was placed on a piece of leather, ſoaked in a mixture of water and ſpirit of wine, the barometer-gage in three trials always indicated a degree of exhauſtion equal to forty-ſeven; but the pear-gage was unaccountably various; in the firſt trial being twelve thouſand, in the ſecond, eleven hundred and fifty; and in the third, five hundred. By theſe experiments it ſufficiently appears, that the uſe of leather ſoaked in water, or in water and ſpirit of wine, prevents the pump from exhauſting to any conſiderable degree. By two other experiments, in which water was uſed for ſoftening the leathers of the piſtons of a common air-pump, we find that the higheſt degree of rarefaction that could be procured was thirty-ſeven, according to the barometer-gage; and thirty-eight according to the pear-gage. Mr. Nairne's laſt experiment furniſhes a very extraordinary evidence of the effect of vapour on the barometer-gage: having put a phial of ether under the receiver, in order to produce artificial cold, and working the pump for half an hour, the degree of exhauſtion indicated by the barometer-gage was only ſixteen; though the ſame pump exhauſted above four hundred times before the ether was put under the receiver. The degree of cold produced by means of ether, in the exhauſted receiver, was 48°, below 0 in Fahrenheit's ſcale, or 103 below 55°, which was the temperature of the air in the room where the experiment was made. Phil. Tranſact. vol. lxvii. part ii. art. 32, page 614, &c.

GAGE *of the Barometer*, is a contrivance for eſtimating the exact degree of the riſe and fall of the mercury in the Torricellian tube. It is well known, that whilſt the mercury riſes in the tube, it ſinks in the ciſtern, and *vice verſâ*; and, as the diſtance between the diviſions graduated on the annexed ſcale and the ſurface of the mercury in the ciſtern is not truly ſhewn by the numbers on the ſcale, errors muſt happen in determining the preciſe height of the mercury. To remedy this inconvenience, a line is cut upon a round piece of ivory, which is fixed near the ciſtern: this line is accurately placed at a given diſtance from the ſcale; *e. gr.* twenty-ſeven inches; and a ſmall float of cork, with a cylindric piece of ivory fixed to its upper ſurface, on which a line muſt be cut at the diſtance of two inches, exactly from the under ſurface of the cork, is left to play freely on the quickſilver, and the cylinder works in a groove made in the other piece: from this conſtruction it appears, that if theſe marks are made to coincide, by raiſing or lowering the ſcrew which acts on the quickſilver, then the diviſions on the ſcale will expreſs the true meaſure of the diſtance from the ſurface.

GAGE *of the Condenſer*, is a glaſs tube of a particular conſtruction, adapted to the condenſing engine, and deſigned to ſhew the exact denſity and quantity of the air contained at any time in the *condenſer*, which ſee. For this purpoſe, let *D d e f c*, *Plate* XIV. *Pneumatics*, *fig.* 5. be a ſmall glaſs tube, about one-tenth of an inch in diameter, open at D, but hermetically ſealed at *c*; D E a larger tube, hermetically ſealed at D, and containing at that end a quantity of mercury, which takes up two or three inches in length, and covers the open end of the ſmaller tube; the other end C, of the larger tube, is ſtrongly cemented into the braſs elbow-piece O E *o* at C, *fig.* 6, ſo as not to be quite at right angles with O *o*, but to incline a little downwards, that the mercury at D may not run towards C, and paſs into the condenſing glaſs G B. This gage is ſcrewed on at *o*, and the injecting ſyringe at O, a cock being interpoſed at O or *o*, or not uſed at all, according to the nature of the experiment. Whilſt air is injected into the condenſing glaſs, and the large tube of the gage at the ſame time, the air in the ſmaller tube, which has no communication with the injected air, muſt be rarer and weaker, and, therefore, the mercury at D will enter the tube, and advance in it, in proportion to the condenſation of the air in G B. In *fig.* 5, *d*, *e*, *f*, repreſent three rings of ſpringy wire, at ſuch diſtances as to ſhew, by the motion of the mercury in the ſmall tube, when the denſity of the air is doubled, tripled, or quadrupled; becauſe the air, which at firſt filled the whole ſmall tube, now takes up only the ſpaces *c d*, *c e*, *c f*; or, in Mr. Hawkſbee's ſtyle, one, two, or three atmoſpheres are thrown in.

Another kind of gage may be put within the condenſing glaſs, at the bottom of it, when the uſe of the preceding gage would be inconvenient. This is a ſhort cylinder of wood, *fig.* 7, about an inch thick, with a hole through its middle between *a* and *b*, of about 1½ inch in diameter; the outward diameter of the cylinder muſt be about four inches, ſo that the cylinder may eaſily ſtand within the condenſing glaſs on the plate, ſupporting its bottom at B, *fig.* 6. There is a hole at A of about ¾ of an inch in diameter, and ¾ of an inch deep, filled with mercury; *a c d b* is a ſmall glaſs tube, open at *a*, but hermetically ſealed at *b*, and bent to a right angle at *c*, the middle of the diſtance between *a* and *b*. When the open end, *a*, is immerſed in mercury, and the air on the ſurface of the mercury condenſed, the air in the tube will recede towards the elbow *c*, and the mercury following it, ſhew to what degree it is condenſed. When the mercury is at *c*, then one additional atmoſphere bears upon its ſurface, and two atmoſpheres, if it be come to *d*; which places are marked by rings of ſpringing braſs wire; at *a* and *b*, about an inch of the ends of the tube are bent to a right angle, that the end *b* may go into the wood, whilſt the end *a* goes under the ſurface of the mercury, where it is held by a cork, whilſt air is injected into the condenſing glaſs. Deſaguliers' Exp. Phil. vol. ii. p. 394, &c.

GAGE, *Sea*. See ALTITUDE.

GAGE, *Bucket Sea*, an inſtrument contrived by Dr. Hales, to find the different degrees of coolneſs and ſaltneſs of the ſea, at different depths: it conſiſts of a common houſhold pail or bucket, with two heads. Theſe heads have each a round hole in the middle, about four inches in diameter, covered with ſquare valves opening upward; and that they may both open and ſhut together, there is a ſmall iron rod fixed to the upper part of the lower valve, and the other end to the lower ſide of the upper valve. So that as the bucket deſcends with its ſinking weight into the ſea, both the valves may open by the force of the water, which by that means has a free paſſage through the bucket. But when the bucket is drawn up, then both the valves ſhut by the force of the water at the upper part of the bucket; ſo that the bucket is drawn up full of the loweſt ſea water to which it has deſcended.

When the bucket is drawn up, the mercurial thermometer fixed in it is examined; but great care muſt be taken to obſerve the degree at which the mercury ſtands, before the lower part of the thermometer is taken out of the water in the bucket, leſt it be affected by the different temperature of the air.

In order to keep the bucket in a right poſition, there are four cords fixed to it, reaching about three feet below it; to which the ſinking weight is fixed.

The reſult of ſeveral trials with this gage was, that when it was let down to different depths, from 360 feet to 5346 feet, in lat. 25° 13′ N. and long. 25° 12′ W., it was diſcovered by the thermometer, that the cold increaſed gradually in proportion to the depths, till it deſcended to 3900 feet, *viz.*

near ¾ of a mile, whence the mercury in the thermometer came up at 53 ; and though it was afterwards ſunk to 5346 feet, *i. e.* a mile and 66 feet, it came up no lower: the warmth of the water upon the ſurface, and that of the air, was all that time 84°.

When the water in the bucket was become of the ſame temperature with that on the ſurface of the ſea, equal quantities of both were weighed and tried by the hydrometer: that from below was found to be the heavieſt, and, conſequently, the ſalteſt. See Treatiſe on Ventilators, part ii. p. 122, &c.

Dr. Hales was probably led to the conſtruction of this ſea-gage from an inſtrument invented by Dr. Hook, and deſigned for the ſame purpoſe. This conſiſts of a ſquare wooden bucket C, *Plate* XVI. *Miſcellany*, *fig.* 1, whoſe bottoms are ſo contrived, that, as the weight A ſinks the iron B, to which the bucket C is faſtened by two handles D, D, on the end of which are the moveable bottoms or valves E, E, and thereby draws down the bucket, the reſiſtance of the water keeps up the bucket in the poſture C, whereby the water, whilſt the bucket is deſcending, hath free paſſage through it; whereas, as ſoon as the bucket is pulled upwards by the line F, the reſiſtance of the water to that motion bears the bucket downwards, and keeps it in the poſture G, whereby the included water is kept from getting out, and the ambient water kept from getting in. Phil. Tranſ. N 9, p. 149, and No. 24, p. 447, or abr. vol. ii. p. 260.

Gage, *Aqueo-mercurial*, is the name of an apparatus contrived by Dr. Hales, and applied, in various forms, to the branches of trees, in order to determine the force with which they imbibe moiſture. Let *e r*, *Plate* XVI. *Miſcellany*, *fig.* 2. be a cylindric glaſs, *e. gr.* of an inch diameter within, and eight inches long. Into this glaſs is introduced the branch of a young thriving apple-tree *b*, about three feet long, with lateral branches; the diameter of the tranſverſe cut *i* being ¾ of an inch. Having fitted the joint *r* to the tube at *r*, by folding a piece of ſheep's ſkin round the ſtem, it is cemented with a mixture of bees'-wax and turpentine melted together in ſuch a proportion, as to make a very ſtiff clammy paſte when cold, and over the cement folds of wet bladders are bound firmly with packthread. To the lower end *e* of the large tube, a ſmaller tube *z e* is cemented, being about ¼ of an inch diameter, and eighteen inches long, and in ſubſtance full ⅛ of an inch thick. Theſe tubes are cemented together at *e* with common hard brick-duſt, or powdered chalk cement, and the joint is farther ſecured with the cement of bees'-wax and turpentine, over which a wet bladder is bound. The apparatus being thus prepared, the branch is turned downwards, and the glaſs tube upwards, and then both tubes are filled with water, with the finger applied to the open end of the ſmall tube, it is inverted and immerſed in the glaſs ciſtern *x*, full of mercury and water. In this ſituation the lower end of the branch was immerſed ſix inches in water, *viz.* from *r* to *i*; the water was imbibed by the branch at its tranſverſe cut *i*; and during its aſcent into the ſap veſſels of the branch, the mercury roſe in the tube *e z* from the ciſtern *x*, ſo that in half an hour it was riſen 5¾ inches high, as far as *z*. The height of the mercury indicated, in ſome meaſure, the force with which the ſap was imbibed, though not the whole force; becauſe, while the water was imbibed by the branch, its tranſverſe cut was covered with innumerable little hemiſpheres of air, and many air-bubbles iſſued out of the ſap-veſſels, which partly filled the tube *e r*, as the water was drawn out of it: and, therefore, the height of the mercury could only be proportional to the exceſs of the quantity of water drawn off above the quantity of the air, which iſſued out of the wood. If the quantity of air, iſſuing from the wood, had been equal to the quantity of water imbibed, it is plain that the mercury could not riſe at all, becauſe there would be no room for it in the tube: but if nine parts in twelve of the water be imbibed by the branch, and only three ſuch parts of air iſſue into the tube in the ſame time, the mercury muſt riſe near ſix inches, and ſo proportionably in other caſes. Dr. Hales obſerved, that the mercury roſe higheſt, in moſt caſes, when the ſun was clear and warm, and that it ſubſided three or four inches towards evening, but roſe again the next day as it grew warm, though ſeldom ſo high as at firſt. Dr. Hales adapted the ſize and ſhape of the glaſs apparatus to a great variety of branches of ſeveral ſizes, and of different kinds of trees, and repeated the experiment above deſcribed, *mutatis mutandis*, in a variety of inſtances. See his Vegetable Statics, vol. i. chap. ii. p. 84, &c.

Gage, *Sliding*, is a tool uſed by mathematical inſtrument makers for meaſuring and ſetting off diſtances: it conſiſts of a beam, tooth, ſliding ſocket, and the ſhoulder of the ſocket.

Gage, *Tide*, is the name of an inſtrument uſed for determining the height of the tides by Mr. Bayly, in the courſe of a voyage towards the ſouth-pole, &c., in the Reſolution and Adventure, in 1772, 1773, 1774, and 1775.

This inſtrument conſiſts of a glaſs tube, whoſe internal diameter was ſeven-tenths of an inch, laſhed faſt to a ten feet fir rod, divided into feet, inches, and quarters: this rod was faſtened to a ſtrong poſt fixed upright and firm in the water. At the lower end of the tube was an exceeding ſmall aperture, through which the water was admitted. In conſequence of this conſtruction, the ſurface of the water in the tube was ſo little affected by the agitation of the ſea, that its height was not altered one-tenth of an inch when the ſwell of the ſea was two feet; and Mr. Bayly was certain, that with this inſtrument he could diſcern a difference of one-tenth of an inch in the height of the tide.

Gage, *Water*. See Altitude and Hydrometer.

Gage, *Weather*, in *Sea Language*. See Gage, above.

Gage *Iſland*, in *Geography*, an iſland in Upper Canada, in the county of Ontario, lying off Kingſton in lake Ontario, between Amherſt iſland and Wolfe iſland.

Gage's *Town*, a ſettlement in Sunbury county, New Brunſwick, on the lands amounting to 20,000 acres, on the weſt ſide of John's river on the northern ſhore of the bay of Fundy.

GAGER *de Ley*. See Wager *of law*.

Gager, *and* Gaging, in *Geometry*. See Gauger. Gauging.

GAGES, in *Geography*, a town of France, in the department of the Aveiron; ſix miles N. E. of Rhodez.

GAGLIARDA, *Ital.* Gaillarde, *Fr.* a gay, frolicſome, and riotous old dance; which, like the modern *waltz*, is almoſt always in triple time. Galliarda, *quaſi* valiarda, from the Latin *validus*, ſtrong, ſtout, powerful, briſk, lively.

This dance has been long out of uſe; but there was a time when the galliarda was a favourite movement, not only with dancers, but with performers on the virginal: as in queen Elizabeth's Virginal book, in that of lady Nevil, and in Parthenia, the galliarda generally ſerves as an allegro to Pavana, a ſlow and ſtately dance, in almoſt every ſuit of leſſons in the three collections by Dr. Bull, Bird, Giles Farnabie, Morley, and others. See Pavana and Parthenia.

GAGNANO, in *Geography*, a town of Naples, in Capitanata; 17 miles E. of Lelina.

GAGNEF,

GAGNEF, a town of Sweden, in Dalecarlia; 15 miles S. W. of Fahlun.

GAGNIER, John, in *Biography*, born and educated at Paris, was a diligent ſtudent in the Hebrew and Arabic languages, in which he became a great adept. He was brought up in the Catholic faith, and when his ſentiments changed in this reſpect, he left France and came to England, where he ſoon acquired the friendſhip of many able and very learned men, among whom were archbiſhop Sharp, and the lord chancellor Macclesfield. He graduated at Cambridge, and likewiſe at Oxford, where he fixed his reſidence for the ſake of conſulting the Bodleian library, and he ſupported himſelf by teaching Hebrew. He publiſhed, in 1706, Joſeph Ben Gorion's Hiſtory of the Jews, in the original Hebrew, with a Latin tranſlation and notes, in a quarto volume. In 1717 he was appointed to read the Arabic lecture at Oxford in the abſence of Dr. Wallis, and upon his death was choſen to the profeſſorſhip in his ſtead, which office he filled with great reputation till his death. He publiſhed two valuable works reſpecting the hiſtory of Mahomet: theſe are, "Iſmael Abulfeda de vita et rebus geſtis Mohammedis, &c. Latine vertit, Prefatione et notis illuſtravit Joh. Gagnier:" and "La Vie de Mahomet, traduite et compilèe de l'Alcoran, des Traditions authentiques de la Sonna, et des meilleurs Auteurs Arabes," 3 vols. 12mo.

GAGNOLA, in *Ichthyology*, a name given by the Spaniards to a ſpecies of the acus, or ſyngnathus of Artedi. The particular ſpecies meant by it, is that called by Artedi the hexagonal bodied ſyngnathus with the pinnated tail; others call it the acus Ariſtotelis, or acus ſecunda, and the French the trompette; we call it ſometimes the needle-fiſh, ſometimes the trumpet-fiſh, and ſometimes the tobacco-pipe fiſh. See Syngnathus.

GAGO, in *Geography*, a kingdom of Africa, with a town of the ſame name, in Negroland; fertile and abounding in corn, rice, and mines of gold. N. lat. 12°. E. long. 2°.

GAGRA, a river of Hindooſtan, which riſes in the lofty weſtern mountains of Thibet, and after a courſe of between 600 and 700 miles, nearly parallel on the eaſt with that of the Ganges, pervading the province of Oude, flows into the Ganges near Chupra: it is now called Surjoo.

GAGUIMPAR, a town of Hindooſtan, in Golconda; 15 miles W. S. W. of Hydrabad.

GAGUIN, Robert, in *Biography*, was born at Colines, in the dioceſe of Amiens. He ſtudied at Paris, took the degree of doctor of laws, and was ſoon after made profeſſor of canon law. In 1473, he was elected general of the order of the Mathurins, and on account of his reputation was employed by Charles VIII. and Louis XII. in various embaſſies in Italy, Germany, and England. He died at Paris in the year 1501. He was conſidered one of the beſt Latin writers of his age, yet his ſtyle is defective in purity and elegance. He was author of many works: of theſe the principal are, 1. "Compendium ſuper Francorum geſtis Pharamundo uſque ad annum 1491." 2. "The Chronicle of Archbiſhop Turpin, tranſlated from Latin into French by command of Charles VIII." 3. "Epiſtolæ et Orationes." 4. "De Puritate Conceptionis Virginis Mariæ." He is ſaid to have given a French tranſlation of Cæſar's Commentaries. Moreri.

GAGUL, in *Geography*, a river of Beſſarabia, which runs into the Danube; eight miles E. of Reni.

GAHALA, in *Botany*, a name given by ſome writers to the *colocaſia*, or great Egyptian arum.

GAHARAN, in *Geography*, a town of Algiers; 60 miles W. S. W. of Tubnah.

GAHNIA, in *Botany*, named by Forſter in honour of Dr. Henry Gahn, a Swediſh botaniſt, whoſe inaugural diſſertation is in the *Fundamenta Agroſtographiæ* of Linnæus. Forſt. Gen. t. 26. Linn. Suppl. 31. Schreb. 235. Willd. Sp. Pl. v. 2. 244. Juſſ. 27. Brown Nov. Holl. v. 1. 238. Lam. Illuſtr. t. 263. Gærtn. fil. t. 181. Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoideæ*, Juſſ.

Gen. Ch. *Cal.* Glumes numerous, imbricated on all ſides, channelled, pointed, the upper, or innermoſt, largeſt, permanent. *Cor.* none. *Nectary*, or briſtles about the baſe of the germen, none. *Stam.* Filaments ſix, rarely but three, capillary, ſhort, greatly elongated after flowering, and permanent; anthers linear, pointed. *Piſt.* Germen oblong; ſtyle thread-ſhaped, erect, longer than the calyx, three-cleft; ſtigmas two to each diviſion, capillary, recurved, rarely ſimple. *Peric.* Nut bony, oblong, angular, ſmooth, encompaſſed with the permanent filaments. *Seed* ſolitary, tranſverſely notched.

Eſſ. Ch. Calyx of numerous imbricated glumes. Filaments elongated after flowering. Style three-cleft. Nut with a ſolitary tranſverſely notched ſeed.

Obſ. We have profited by the remarks of Mr. R. Brown and of Gærtner, aſſiſted by our own examination of the plants of this genus, to render its character more faithful. The corolla and nectary of Linnæus are probably interior more delicate ſcales, found in the flowers of ſome ſpecies, but we ſuſpect not in all. The flowers are truly ſimple and diſtinct, each reſembling a ſpikelet, but conſiſting of a rachis or receptacle clothed with imbricated ſcales and crowned with the organs of impregnation.

1. G. *procera*. Linn. Suppl. 211. Forſt. Prod. 25. Nov. Act. Upſ. v. 3. 178. - Panicles ſpicate, numerous, elongated. Nut priſmatic, oblong.—Native of New Zealand, near Duſky Bay. A hard, rigid, ruſhy plant, three or four feet high. *Leaves* narrow, channelled, rough. *Panicles* ſlender, aggregate, leafy, with blackiſh, broad, long-pointed bracteas, extending beyond the flowers. *Nut* light brown, priſmatic, equally tapering at both ends. *Stigmas* deeply divided, The long, brown, permanent filaments are very remarkable.

2. G. *ſchœnoides*. Forſt. Prod. 26.—Culm zig-zag. Panicles compound, ſpicate, crowded. Nut obovate, obtuſe; priſmatic at the baſe.—Native of Otaheite. *Panicles* more denſe and crowded than in the former, with broader bracteas. The broader blunt fruit at once diſtinguiſhes it. Mr. Brown refers this ſpecies to his new genus *Lampocarya*, in which the ſeed is not tranſverſely notched.

3. G. *pſittacorum*. Billard. Nov. Holl. v. 1. 89. t. 115. Brown. Nov. Holl. v. 1. 238.—Panicle repeatedly compound. Nut nearly globular. Glumes obtuſe. Permanent filaments criſped.—Native of Van Diemen's Land. The *leaves* of this are externally remarkably rough. The large, cloſe, repeatedly branched, black panicle, and ſhining brown fruit, reſemble ſome of the large tropical ſpecies of *Holcus* or *Andropogon*. The *flowers* are very taper at their baſe, with numerous, gradually leſſening, ſcales.

4. G. *leucocarpa*. Brown 239.—"Panicle repeatedly compound. Glumes bluntiſh. Nuts opaque, with an acute withered point."—Native of the ſouth coaſt of New Holland. *Brown*. Of this we have ſeen no ſpecimens.

5. G. *erythrocarpa*. Brown 239.—Panicle repeatedly compound. Glumes all acute. Nuts nearly elliptical, ſhining, and coloured.—Native of New South Wales, about Port Jackſon and Botany Bay. *Herb. Banks.*—Like the third ſpecies, but more ſtriking and beautiful on account of its

its ſcarlet *fruit*, which is ſcarcely half ſo large as in that, and not obovate, but elliptical, inclining to globoſe.

6. G. *melanocarpa*. Brown 239.—Panicles ſpicate, numerous. Glumes all acute. Nuts broadly elliptical, pointed, poliſhed. Stamens three. Stigmas undivided.—Native of New South Wales and Van Diemen's Land. The *panicle* has the habit of the two firſt ſpecies, but is ſmaller and paler. The *fruit* is ſhining and very black. *Leaves* ſmooth at the back. According to Mr. Brown, who has examined the living flowers, their ſtamens are but three, and the ſtigmas are ſimple, yet there can be no doubt reſpecting the genus.

7. G. *trifida*. Billard. Nov. Holl. v. 1. 89. t. 116. (Lampocarya? hexandra; Brown Nov. Holl. v. 1. 238.) Panicles denſe, capitate. Glumes all pointed. Nuts nearly globular, poliſhed. Stigmas undivided.—Native of Van Diemen's Land. Remarkable for the capitate *panicles*. The *fruit* is ſaid to be blueiſh.

GAHNITE, in *Mineralogy*, one of the recently diſcovered Swediſh foſſils, of which Meſſrs. Eckeberg and Vauquelin have given the analyſes. It is found maſſive and in ſmall and middle-ſized octohedral cryſtals, imbedded in a talcoſe rock. The colour is deſcribed as greeniſh-black, greeniſh-brown, and perfect liver-brown in the imperfect ſpecimens we have had an opportunity of examining; nor were we able to diſcover a metallic luſtre as mentioned by Haüy. Internally it is dull. Fracture imperfectly conchoidal. Hardneſs ſufficiently great to ſcratch quartz. It is infuſible before the blow-pipe, except here and there on the ſurface of ſmall fragments, which becomes cracked and white. It does not act on the magnetic needle. Specific gravity, according to Haüy, 4.6969. The conſtituent parts of gahnite are thus ſtated:

Eckeberg.		Vauquelin.	
Alumine	60	Alumine	42
Silica	4	Silica	4
Oxyd of zinc	24	Oxyd of zinc	28
Iron	9	Sulphur	17
Loſs	3	Oxyd of iron	5
	100	Parts not acted on	4
			100

The quantity of this ſubſtance operated on by Vauquelin was not ſufficient to allow him to vary his experiments. He conjectures that the zinc exiſts in it in the ſtate of blende, and thinks it probable that the alumine and ſilica are united with this ſulphuret of zinc.

Haüy refers this ſubſtance, with a query, to his ſpinelle, as ſpinelle zincifère; while Brongmart adds it to the zinc genus, under the name of zinc gahnite. The advantage of giving to new mineral ſubſtances names unconnected with theory and ſyſtem, is illuſtrated by the inſtance of gahnite. While the latter name may be retained, whatever be the place this ſubſtance is to occupy hereafter in the ſyſtem, one at leaſt of the juſt mentioned denominations of the French mineralogiſts muſt contribute to ſwell its ſynonomy, which, conſidering the recency of the diſcovery of this foſſil, is already ſufficiently enriched by the propoſed appellations of fahlun-cryſtals, fahlunite, automalite, and zinciferous corundum, which laſt, by the editor of a French journal, has been converted into corindon ſanguiferè.

GAJA, in *Geography*, a town of Italy, in the department of the Panaro; 20 miles S. of Modena.

GAIANITES, GAIANITÆ, a ſect of ancient heretics, ſprung from the Eutychians.

This ſect was of an older ſtanding than Gaian, a biſhop of Alexandria in the ſixth century, from whom, however, they took their name. They adhered to the opinion of Julian Halicarnaſſeus, the chief of the Incorruptibles and Phantaſtici; and came, at length, to be denominated Gaianites, upon Gaian's putting himſelf at their head. They denied that Jeſus Chriſt, after the hypoſtatical union, was ſubject to any of the infirmities of human nature.

GAJARA, in *Geography*, a town of Hindooſtan, in the circar of Gohud; 12 miles N. of Narwa.

GAICKEN, a town of Pruſſia, in the palatinate of Culm; five miles N. E. of Straſburg.

GAIDEROPSARUS, in *Ichthyology*, a name given by ſome to a fiſh of the truttaceous kind, caught in the Mediterranean, and more uſually called *callarias*.

GAIDRONISI, or GAITHERONESI, *i. e. Aſſes' iſland*, in *Geography*, a ſmall iſland in the Mediterranean, near the ſouth coaſt of Candia; a mere rock, producing only a few branches of thyme, and inhabited only by wild pigeons. It was fortified by Patroclus, and once bore his name, when he was deputed by the Egyptians to aſſiſt the Athenians againſt Antigonus, the ſon of Demetrius. N. lat. 34° 48′. E. long. 25° 45′.

GAJERAM, a town of Hindooſtan, in the circar of Rajamandry; 15 miles N. W. of Rajamandry.

GAIGNY, or GAGNY, JOHN, in *Biography*, was probably born at Paris in the beginning of the 16th century, for in the year 1526 he had taken the degree of bachelor, and held the appointment of *procureur*, or attorney for the French nation in the univerſity. He was afterwards lecturer in theology at the college of Navarre and rector of the univerſity. In 1531 he took his degree as doctor of divinity, and filled the poſt of chancellor of the univerſity from the year 1546 till the cloſe of 1549, when he died. Gaigny was deeply read in the ancient languages, and highly eſteemed as a Latin poet: his ſovereign, Francis I., entertained ſo great a regard for him, that he frequently conſulted him on ſubjects of literature, and made him his firſt almoner. He was author of many works, all of which were more or leſs connected with theology. Of theſe, the moſt important conſiſt of "Commentaries" upon the different books of the New Teſtament, in which he explains the literal ſenſe by a kind of paraphraſe. He is applauded by Dupin on account of his deep learning and ſolid judgment, who, ſpeaking of his writings, ſays, "his notes will be found of admirable uſe to thoſe who deſire to read the text of the New Teſtament, and to comprehend the ſenſe of it without ſtopping at any difficult places, and without having recourſe to larger commentaries." His Scholia on the four evangeliſts and on the Acts of the Apoſtles, are inſerted in the Biblia Magna of Father John de la Haye. Moreri.

GAILDORF, or GAILENDORF, in *Geography*, a town of Germany, in the lordſhip of Limburg, on the Kocher; 38 miles W.S.W. of Anſpach. N. lat. 49°. E. long. 9° 54′.

GAILLAC, a town of France, and principal place of a diſtrict in the department of the Tarn, ſituated on the Tarn, which is here navigable; 27 miles N.E. of Toulouſe. The place, which has conſiderable trade, and furniſhes from its environs good wine, contains 6,465, and the canton 13,364 inhabitants, on a territory of 217½ kiliometres, in 11 communes. N. lat. 43° 53′. E. long. 1° 58′.

GAILLON, a town of France, in the department of the Eure, and chief place of a canton in the diſtrict of Louviers;

viers ; 7 miles S.E. of Louviers. The place contains 980, and the canton 11,966 inhabitants, on a territory of 195 kiliometres, in 35 communes.

GAILNAU, a town of Franconia ; 5 miles S. of Rothenburg.

GAILOVSKI, a fortreſs of Ruſſia, in the government of Caucaſus, on the Ural ; 12 miles N.E. of Uralſk.

GAIMERSHEIM, a town of Germany, in Upper Bavaria ; 2 miles N.W. of Ingolſtadt.

GAIN, the profit, or lucre, a perſon reaps from his trade, employment, or induſtry.

Some derive the word from the German *gewin ;* whereof the Italians had made *guadagno ;* the French and Engliſh *gain.*

There are legal and reputable gains, as well as ſordid and infamous ones. What is gained beyond a certain ſum, by gaming, is all liable to be reſtored again, if the loſer will take the benefit of the law.

GAIN, in *Carpentry*, the ſloping part of the ſhoulder of a tenon, which has an additional ſupport below, projecting as far as the bottom of the ſloping part, in order to ſtrengthen the tenon.

To GAIN *the wind*, in *Sea Language*, is to arrive on the weather-ſide, or to windward of ſome other veſſel in ſight, when both are plying to windward, or ſailing as near the wind as poſſible.

GAINAGE, GAINAGIUM, in our *Ancient Writers*, ſignifies the draught-oxen, horſes, wain, plough, and furniture, for carrying on the work of tillage by the baſer ſort of ſokemen and villains.

Gainage is the ſame with what is otherwiſe called *wainage.* Bracton, lib. i. cap. 9. ſpeaking of lords and ſervants, ſays, " Ut ſi eos deſtruant, quod ſalvum non poſſit eis eſſe wainagium ſuum." And again, lib. iii. tract. 2. cap. 1. " Villanus non amerciabitur, niſi ſalvo wainagio ſuo." For anciently, as it appears both by Mag. Chart. and other books, the villain, when amerced, had his gainage, or wainage, free ; to the end his plough might not ſtand ſtill ; and the law, for the ſame reaſon, does ſtill allow a like privilege to the huſbandman ; that is, his draught-horſes are not, in many caſes, diſtrainable.

GAINAGE is alſo uſed for the land itſelf, or the profit raiſed by cultivating it.

GAINAS, in *Biography*, a ſoldier under the eaſtern emperors, who was, on account of his valour, raiſed by Theodoſius to the command of all the Goths and other barbarians in his ſervice. He attached himſelf to Stilicho, and was employed by him in the maſſacre of the prefect Rufinus : Gainas gave the ſignal of death, and a daring ſoldier plunged his ſword into the breaſt of the guilty prefect, who fell, groaned, and died at the feet of the affrighted emperor. As a reward of this deed, he was created by Eutropius a general of the Roman army, but diſſatisfied with his ſituation, and diſdaining to ſubmit to the orders of a baſe eunuch, he is ſuppoſed to have fomented the revolt of his countryman Tribigild, with whom he was connected by a domeſtic, as well as by a national alliance. He took the command againſt the rebel, but was ſecretly inclined to favour his cauſe, and in a few months openly united his forces to thoſe of Tribigild, and after plundering ſeveral provinces, advanced to Conſtantinople, and Arcadius the emperor reſigned his authority and his perſon into the hands, and upon the faith of the barbarians. The church of Euphemia was ſelected as the place of the interview. Gainas bowed with reverence at the feet of the emperor, but demanded the ſacrifice of his miniſters Aurelianus and Saturninus, and when the axe was lifted up over their bare necks, he declared himſelf contented to commute the capital part of the puniſhment into perpetual exile. In his early youth Gainas had paſſed the Danube as a ſuppliant and fugitive : his elevation had been the work of valour and fortune, and his indiſcreet or perfidious conduct was the cauſe of his downfall. He claimed for himſelf and his Arian followers the poſſeſſion of a peculiar church, but the public toleration of hereſy wounded the pride of the catholics : every quarter of Conſtantinople was filled with tumult and diſorder. The barbarians gazed with ſuch ardour on the rich ſhops of the jewellers, and the tables of the bankers, which were covered with ſilver and gold, that it was judged prudent to remove thoſe dangerous temptations from their ſight. They reſented the injurious precaution, and attempted to attack and deſtroy with fire the imperial palace : in the tumult ſeven thouſand of the Goths periſhed, Gainas was declared a public enemy ; and in a ſhort time afterwards he, and the greater part of his followers, were ſlain in a battle with the king of the Huns. Univer. Hiſt. Gibbon, vol. v.

GAINBATESA, in *Geography*, a town of Naples, in the county of Moliſe ; 18 miles E.S.E. of Moliſe.

GAINING *of a Mine*, or " putting down the foundation," are terms for the ſinking of ſhafts, and, by means of engines or ſoughs, laying the vein or ſtratum dry which is intended to be wrought. See MINING.

GAINING *of Land from the Sea*, is a term for excluding the tide from a tract of flat land on the ſea-ſhore by means of artificial banks, and conſtructing the neceſſary drains and ſluices for venting the ſpring or ſoakage, and the rain waters of ſuch tract, into the ſea at low water, or lifting the ſame by means of fen-mills, engines, &c. (See EMBANKMENT.) By ſtudying attentively the form in which the tides and waves throw up and maintain banks of ſand and ſhingle between low and high-water mark, on the Norfolk coaſt, north of Yarmouth, Mr. William Smith the engineer, a few years ago, ſucceeded in imitating ſuch banks by art without ſide of the principal ſea-walls or mounds, and which outer or break-water banks, though compoſed only of ſand and ſhingle, in the proper ſhape and direction, which is ſomewhat oblique to the line of coaſt, remain and operate effectually in breaking the force of the waves and protecting the ſea-walls from the ravages which they had previouſly experienced on the occurrence of certain winds with the ſpring tides. The Board of Agriculture, and the Society of Arts, annually offer premiums for gaining land from the ſea, and from their communications and tranſactions much valuable information is to be gathered.

The gaining of land from the ſea is ſometimes effected by the operations of nature, with very little or no aſſiſtance from art, as has happened in the neighbourhood of Old Romney, in Kent, and near Sandwich in the ſame county, and numerous other places : while in other, and more numerous inſtances, land is progreſſively loſt by the undermining and waſhing away of matters compoſing the cliffs. (See ENCROACHMENT *of the Sea.*) M. De Sauſſure, in the fifth chapter of his Agenda, or obſervations to be made, as the foundation of a theory of the earth, inſerted in N° 20 of the " Journal des Mines," has enumerated ſome of the principal obſervations to be made relative to the gaining or loſs of land on the coaſts of the ocean, in different countries : a tranſlation of which will be found in the Philoſophical Magazine, vol. iii. p. 40 ; which obſervations, if multiplied, would prove of important uſe in geological inveſtigations. In M. de Luc's Geological Travels, vol. i. pages 350. 393, &c. lately publiſhed, are ſome curious particulars on this ſubject.

GAINSBOROUGH, THOMAS, in *Biography*, a

painter endowed with very extraordinary talents, which he exerciſed in landſcapes and in portraits, to the honour of the country and age in which he lived. He was born in 1727 at Sudbury in Suffolk, and at a very early age diſcovered his propenſity to painting. Nature was his teacher, and the woods of Suffolk his academy. There he would paſs in ſolitude his mornings, in making ſketches of an antiquated tree; a marſhy brook; a few cattle; a ſhepherd and his flock, or any other objects which accidentally preſented themſelves. Before he was twelve years old he had painted many pictures; and about that time went to London, where he ſoon found it neceſſary to try what effect he could produce in portraiture. In this alſo he was ſucceſsful; and acquired very conſiderable practice and reputation; enjoying great favour with the public for many years.

His ſtyle of execution, as well as choice of ſubjects, was original, although conſiderably reſembling that of Watteau, more particularly in his landſcapes. His pictures are generally wrought in a looſe and ſlight manner, with great freedom of hand, and uſing very little colour, with a great body of vehicle; which gives to his works great lightneſs and looſeneſs of effect; properties extremely valuable in a picture, and too eaſily loſt in the endeavour to give more ſtrict and poſitive reſemblance of ſubſtance. Sir Joſhua Reynolds in his fourteenth lecture ſays of this hatching manner of Gainſborough, that his portraits were often little more than what generally attends a dead colour as to finiſhing or determining the form of the features; but as he was always attentive to the general effect, or whole together, I have often imagined (ſays he) that this unfiniſhed manner contributed even to that ſtriking reſemblance for which his portraits are ſo remarkable. At the ſame time it muſt be acknowledged that there is one evil attending this mode; that if the portrait were ſeen previouſly to any knowledge of the original, different perſons would form different ideas; and all would be diſappointed at not finding the original correſpond with their own conceptions, under the great latitude which indiſtinctneſs gives to the imagination, to aſſume almoſt what character or form it pleaſes."—"To ſhew the difficulty of uniting ſolidity with lightneſs of manner we may produce a picture of Rubens in the church of St. Judule at Bruſſels as an example; the ſubject is Chriſt's charge to Peter: which, as it is the higheſt and ſmootheſt finiſhed picture I remember to have ſeen of that maſter, ſo it is by far the heavieſt."—"A lightneſs of effect produced by colour, and that produced by facility of handling, are generally united. A copy may preſerve ſomething of the one, it is true; but hardly ever of the other."—"Gainſborough poſſeſſed this quality of lightneſs of manner and effect, I think, to an unexampled degree of excellence; but it muſt be remembered at the ſame time that the ſacrifice which he made to this ornament of our art was too great; it was in reality preferring the leſſer excellencies to the greater."

In the ſame lecture, which principally treats of the acquirements of Gainſborough and which was delivered at the Royal Academy ſoon after his death, by its truly exalted preſident, it is ſaid of him, "that if ever this nation ſhould produce genius ſufficient to acquire to us the honourable diſtinction of an Engliſh ſchool, the name of Gainſborough will be tranſmitted to poſterity in the hiſtory of the art among the firſt of that riſing name."—"Whether he moſt excelled in portraits, landſcapes, or fancy pictures, it is difficult to determine: whether his portraits were moſt admirable for exact truth of reſemblance, or his landſcapes for a portrait-like repreſentation of nature, ſuch as we ſee in the works of Rubens, Ryſdael, or others of theſe ſchools. In his fancy pictures, when he had fixed upon his object of imitation, whether it was the mean and vulgar form of a wood-cutter, or a child of an intereſting character, as he did not attempt to raiſe the one, ſo neither did he loſe any of the natural grace and elegance of the other; ſuch a grace and ſuch an elegance as are more frequently found in cottages than in courts. This excellence was his own, the reſult of his particular obſervation and taſte. For this he was certainly not indebted to any ſchool; for his grace was not academical, or antique, but ſelected by himſelf from the great ſchool of nature; where there are yet a thouſand modes of grace unſelected, but which lie open in the multiplied ſcenes and figures of life, to be brought out by ſkilful and faithful obſervers.

"Upon the whole we may juſtly ſay, that whatever he attempted he carried to a high degree of excellence. It is to the credit of his good ſenſe and judgment that he never did attempt that ſtyle of hiſtorical painting for which his previous ſtudies had made no preparation."

Nothing could have enabled Gainſborough to reach ſo elevated a point in the art of painting without the moſt ardent love for it. Indeed his whole mind appears to have been devoted to it, even to his dying day; and then his principal regret ſeemed to be, that he was leaving his art, when, as he ſaid, "he ſaw his deficiencies, and had endeavoured to remedy them in his laſt works." Various circumſtances in his life exhibited him as referring every thing to it. "He was continually remarking to thoſe who happened to be about him, whatever peculiarity of countenance, whatever accidental combination of figures, or happy effects of light and ſhadow occurred in proſpects, in the ſky, in walking the ſtreets, or in company. If in his walks he found a character that he liked, and whoſe attendance was to be obtained, he ordered him to his houſe: and from the fields he brought into his painting-room ſtumps of trees, weeds, and animals of various kinds; and deſigned them not from memory, but immediately from the objects. He even framed a kind of model of landſcapes on his table compoſed of broken ſtones, dried herbs, and pieces of looking-glaſs; which he magnified, and improved into rocks, trees, and water: all which exhibit the ſolicitude and extreme activity that he had about every thing relative to his art; that he wiſhed to have his objects embodied as it were, and diſtinctly before him, neglecting nothing that contributed to keep his faculties alive; and deriving hints from every ſort of combination."

He was alſo in the conſtant habit of painting by night, a practice very advantageous and improving to an artiſt, for, by this means, he may acquire a new and a higher perception of what is great and beautiful in nature. His practice in the progreſs of his pictures was to paint on the whole together; wherein he differed from ſome, who finiſh each part ſeparately, and by that means are frequently liable to produce inharmonious combinations of forms and features.

Gainſborough was one of the few artiſts of eminence this country has produced who never was indebted to foreign travel for his improvement and advancement in painting. Some uſe indeed he appears to have made of foreign productions; and he did not neglect to improve himſelf in the language of the art, the art of imitation, but aided his progreſs by cloſely obſerving and imitating ſome of the maſters of the Flemiſh ſchool; who are undoubtedly the greateſt in that particular and neceſſary branch of it. He frequently made copies of Rubens, Teniers, and Vandyke, which it would be no diſgrace to the moſt accurate connoiſſeurs to miſtake for original pictures at firſt ſight. What he thus learned, he did not however ſervilely uſe, but applied it to imitate nature in a manner entirely his own.

The ſubjects he choſe for repreſentation were generally very ſimple, to which his own excellent taſte knew how to give expreſſion and value. In his landſcapes a riſing mound and a few figures ſeated upon, or near it; with a cow or ſome ſheep grazing, and a ſlight marking of diſtance, ſufficed for the objects: their charm was the purity of tone in the colour; the freedom and clearneſs of the touch; together with an agreeable combination of the forms: and with theſe ſimple materials, which appear ſo eaſy as to be within every one's graſp, but which conſtantly elude the deſigner who is not gifted with his feeling and taſte, does he always produce a pleaſing picture. In his fancy pictures the ſame taſte prevailed. A cottage girl; a ſhepherd's boy; a woodman; with very ſlight materials in the background, were treated by him with ſo much character, yet ſo much elegance, that they never fail to delight.

He was an excellent muſician, playing with exquiſite taſte on the violin. His mind and manners were urbane and kind. If he ſelected for the exerciſe of his pencil an infant from a cottage, all the tenants of the humble roof generally participated in the profits of his picture; and ſome of them frequently found in his habitation a permanent abode. His liberality was not confined to this alone; needy relatives and unfortunate friends were further incumbrances on a ſpirit that could not deny; and owing to this generoſity of temper, that affluence was not left to his family which ſo much merit might promiſe, and ſuch real worth deſerve. He died, ſincerely regretted by every lover of art, in 1788, aged 61, leaving behind him a very numerous body of works, both pictures and drawings; which are now ſcattered over every part of this country.

GAINSBOROUGH, in *Geography*, a market town of Lincolnſhire, England, is ſeated on the eaſtern bank of the river Trent, and conſiſts principally of one ſtreet. In the year 1801 the town conſiſted of 1064 houſes, which were occupied by 4506 perſons. The river is navigable to this place for veſſels of 150 tons burthen. By means of this ſtream, which unites with the Humber river, and the Readley and Cheſterfield canals, a conſiderable trade in corn and other commodities is carried on.

According to ancient hiſtory, it is related that king Sweyne anchored near this town with ſeveral Daniſh veſſels, in one of his depredatory expeditions to Britain. Matthew of Worceſter alſo ſtates, that the ſame monarch was murdered at this place. Leland deſcribes an old ſtone-chapel in the ſouth part of the town, wherein, according to tradition, ſeveral Danes were interred. In the time of king Edward I., William de Valence, then lord of the manor, obtained a charter, or grant, from the monarch for holding a fair here. During the civil wars between king Charles and the parliament, this town was much injured by the contending parties.

The church is a modern pile of irregular building. In 1791 a fine ſtone bridge, with three elliptical arches, was raiſed over the river Trent. It is private property, and paſſengers and carriages of all ſorts are ſubjected to a toll for paſſing over. An old hall, commonly called the palace, is a ſingular edifice. It is conſtructed principally of oak timber framing, and forms three ſides of a quadrangular. This building was formerly ſurrounded by a moat, and had large gardens and fiſh-ponds, &c. attached to it. Tradition aſcribes it to John of Gaunt, duke of Lancaſter, but it appears of a later age.

William de Gainſborough was a native of this place. He was an ambaſſador from king Edward I., and for his zealous defence of the pope's infallibility, was, by Boniface VIII. preferred to the ſee of Worceſter, where he died, A.D. 1308. Simon Patrick, biſhop of Ely, was born here in 1626, and died in 1707. About half a mile north of the town are ſome embankments, called "the Caſtle Hills." Theſe are ſaid to have been firſt formed by the Romans, and afterwards altered and enlarged by the Danes. See Beauties of England, vol. ix.

GAIOPHRAGNIA, in *Natural Hiſtory*, a genus of the firſt order of *ſeptariæ*, divided by partitions of earthy matter.

GAIRSA, in *Geography*, one of the ſmaller Orkney iſlands, N.E. of Pomona. N. lat. 58° 51'. W. long 2° 51'.

GAISSERN, a town of the duchy of Stiria; 12 miles E. of Rottenmann.

GAIT, as applied to horſes, is a term that implies their method of going, or what is ſometimes called their action.

GAIT, in *Rural Economy*, is the name of a ſort of open door, made uſe of for forming the entrance into an incloſure, &c. It alſo denotes a by-way acroſs a common field; and the going of a cow, or other animal, in a ſummer paſture. A ſingle ſheaf of corn bound near the top, and ſet upon its butt end to dry, is likewiſe in ſome places called a gait. See GATE and *Harveſting* GRAIN.

GAITERS, a ſort of ſpatter-daſhes, uſually made of cloth, which are either long and reaching to the knee, or ſhort, and only extending juſt above the ankle.

GAL, *St.* See *St.* GALLEN.

GALA WATER, in *Geography*, a river of Scotland, which runs into the Tweed, about 2 miles above Melroſs, in Roxburghſhire.

GALABA, in *Ancient Geography*, a ſmall town of Aſia, ſituated in the mountains, whence the river Calabas ſprung.

GALACTITES, in *Mineralogical Antiquities*, a ſtony ſubſtance differently deſcribed by different authors of antiquity, who ſcarcely agree in any other point reſpecting its characters but that of its producing, when broken and triturated with water, a white fluid, comparable to milk (γαλα). This latter circumſtance has likewiſe given riſe to the appellations of galaxia, leucogæa, leucographa, expreſſive of that quality; and it was alſo called, or rather confounded with, morochtus and ſynophytes. According to Pliny it was found in the Nile, and other rivers, where it ſometimes occurred, marked with red veins. It is recommended for its property of increaſing the milk of nurſes, and hung on the necks of children, for promoting ſalivation and dentition. Sir John Hill, ever ready to deſcribe what had not come under his obſervation, acquaints us that the galactites of the ancient writers is a very hard and dry ſubſtance, like an indurated clay, of a cloſe compact texture, very heavy, and in colour of a pale-grey without the leaſt admixture of any other tinge; that it is of a leſs even ſurface than the morochtus, and leſs hard; that it melts but ſlowly in the mouth, and leaves ſomething of a luſcious ſweetneſs on the tongue; that it does not adhere to the lips, nor ferment with acids, and in burning becomes of a pure white. This deſcription is not applicable, in all its parts, to any one mineral ſubſtance we are acquainted with; while the deſcription which others have given of galactites applies to ſeveral ſubſtances; and, indeed, various ſubſtances endowed with the quality alluded to muſt neceſſarily have been confounded at a period when the ſcience of diſcriminating natural ſubjects was entirely unknown, and when ſimilarity in ſome uneſſential external character was deemed ſufficient to apply one and the ſame name to things not bearing any affinity to each other.

Some of the modern writers on mineralogy have conſidered galactites as the ſame with morochtus, which is ſuppoſed to be the pulverulent variety of carbonate of lime, called mountain-

mountain-milk; but their reaſons for this conjecture are as ill founded as thoſe of others who think the galactites of the ancients to be ſoap-ſtone, lithomarge, jaſper, &c. Fortunately, neither the mineralogiſt nor the phyſician and antiquary have any reaſon to regret the ignorance in which they are kept with regard to the true meaning of the name in queſtion, which ſhould be expunged from the ſyſtems of ocryctognoſy.

GALACTOIDES, Γαλακτοειδης, of γαλα, *milk*, and ειδος, *form*, *milky*, a word uſed by the ancients in two or three different ſenſes. Some uſed it to expreſs tepid, or little warm, with ſuch a heat as that of milk juſt drawn from the cow; others expreſſed by it a white, ſomewhat opaque, or milky-colour; others expreſſed by it only a want of tranſparence in fluids. Galen frequently uſes it in the ſecond of theſe ſenſes, when treating of urines.

GALACTOPHAGI, and GALACTOPOTÆ, in *Antiquity*, perſons who lived wholly on milk, without corn, or the uſe of any other food.

The words are compounded of γαλα, γαλακτος, *milk*; φαγειν, *to eat*; and ποτης, of πινω, *I drink*.

Certain nations in Scythia Aſiatica, as the Getæ, Nomades, &c. are famous, in ancient hiſtory, in quality of galactophagi, milk-eaters. Homer makes their eloge, Iliad, lib. iii.

Ptolemy, in his Geography, places the galactophagi between the Riphæan mountains on one ſide, and the Hircanian ſea on the other.

GALACTO-PHORI DUCTUS, in *Anatomy*, from γαλα, *milk*, and φερω, *I bear*, the lacteals, ſo named from the milky appearance of the fluid (chyle) which they contain. The excretory tubes of the mammary gland are alſo deſcribed under the ſame name. See BREAST.

GALACTOPSIA, a method of curing diſeaſes by drinking milk only. The gout, conſumption, and many other chronical diſeaſes, are by many affirmed to be curable by this means. See Cheyne's Nat. Meth. of curing Diſeaſes.

GALACTOSIS, of γαλακτοσμαι, *to be converted into milk*, the production of milk; or the action whereby the food, or chyle, is converted into milk.

GALACTOSPONDA, Γαλακτοσπονδα, of γαλα, *milk*, and σπονδη, *libation*, in *Antiquity*, a libation made with milk.

GALACUM, in *Ancient Geography*, a place of Britain, marked in the tenth rout of Antonine, and ſuppoſed to be Appleby between Whitley caſtle and Overborough.

GALACZ, or GALATZ, in *Geography*, a town of European Turkey, in Moldavia, on a lake near the conflux of the Prut and the Danube, chiefly inhabited by Greeks; 120 miles S.S.W. of Bender. N. lat. 45° 24'. E. long. 28° 24'.

GALADA, in *Ancient Geography*, a country of Arabia, called by Stephanus *Galadene*, and mentioned by Joſephus, and ſuppoſed to be referred to by Moſes in his account of the treaty between Jacob and Laban.

GALADES, in *Natural Hiſtory*, an epithet given by Rondeletius to a ſpecies of chama, remarkable for its milky whiteneſs. It is derived from the Greek Γαλη, *milk*.

This chama is a very elegant ſhell.

GALAFIGUERA, CAPE, in *Geography*, a cape on the S. coaſt of Majorca. N. lat. 39° 36'. E. long. 2° 27'.

GALAICA REGIO, in *Ancient Geography*, a country of Thrace, in which were ſituated the following towns; *viz.* Sala, Zona, Meſambria, and Stryma; and ſaid by Herodotus (l. vii.) to have been denominated "Regio Britannica."

GALAN, a town of France, in the department of the Higher Pyrenées, and chief place of a canton in the diſtrict of Tarbes; 15 miles E. of Tarbes. The place contains 1294, and the canton 7618 inhabitants, on a territory of 102½ kiliometres, in 10 communes.

GALANGAL, GALANGA, a medicinal root, brought from the Eaſt Indies; the produce of a plant of the ſame name.

Its characters are theſe. It hath a ſingle ſpatha of one leaf; the flower has one petal with a ſlender tube, divided in ſix parts, three of them alternately oval and ſpear-ſhaped, the other oval, and at bottom cut into two parts, which are vertically heart-ſhaped; and it hath one ſtamen which is membranaceous: it has a round germen, ſupporting a ſtyle the length of the tube; which afterwards become a roundiſh three-cornered capſule with three cells filled with ſeeds. We have but one ſpecies of this plant in England, known by botanical writers under the title of *Kæmpferia*, which ſee.

There are two kinds of galangals, the *ſmall* and the *great*. The ſmaller is by far the moſt in eſteem, and is almoſt the only one heard of in preſcription. The *galanga minor*, or leſſer galangal, is a ſmall ſhort root, of an irregular figure, of the thickneſs of a man's little finger, and is ſeldom met with in pieces of more than an inch or two long. It has ſeveral protuberances at its ends, and on its ſurface, and is ſurrounded with many circular rings, that ſtand out a little beyond the reſt of the ſurface. It is of an extremely firm, and compact texture, yet not heavy; it cuts difficultly with a knife, and leaves a poliſhed ſurface. Its colour is a browniſh red on the outſide, and a ſomewhat brighter red within, though ſtill with a conſiderable admixture of brown.

The ſmall galangals are to be choſen full and plump, and of a bright colour, very firm and ſound, and of an acrid and inſupportable hot taſte.

They were formerly in common uſe as warm ſtomachic bitters, and generally made an ingredient in bitter infuſions; but they are now almoſt wholly laid aſide, on account of their unpleaſant flavour. Bitterneſs does not appear to be the proper medical character of this root; the heat and pungency greatly prevailing. A very fiery extract is made from it with rectified ſpirit, and the watery extract is alſo very hot and pungent: in diſtillation with water, it yields an eſſential oil, about a dram in quantity from ſixteen ounces, of little ſmell, and no great pungency: ſo that the pungent matter of the galangal appears to be of the ſame nature with that of pepper, reſiding not in the volatile oil, but in a more fixed matter. Lewis, Mat. Med.

The larger galangal grows chiefly in Java and Malabar, and anſwers pretty much to the above deſcription, only that it is larger in bulk, leſs unequal and tuberous, weaker, and more diſagreeable than the leſſer kind. The galangals are both brought us from the Eaſt Indies, and are the roots of the ſame plant, which is of the number of the *herbæ bulboſis affines* of Mr. Ray. Herman calls that which produces the larger, *bauchale Indorum*; and that which produces the leſſer, *lagoudi Indorum*.

The people of the Eaſt Indies uſe theſe roots by way of ſpice.

GALANT. See GALLANT.

GALANTHUS, in *Botany*, from γαλα, *milk*, and ανθος, *a flower*, alluding to its milky whiteneſs. Snow-drop. Linn. Gen. 160. Schreb. 215. Willd. Sp. Pl. v. 2. 29. Sm. Fl. Brit. 352. Mart. Mill. Dict. v. 2. Lamarck Illuſtr. t. 230. Juſſ. 55. Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Spathaceæ*, Linn. *Narciſſi*, Juſſ.

Gen. Ch. *Cal.* Spatha oblong, obtuſe, compreſſed, opening at the flat ſide, permanent, moſtly cloven at the top. *Cor.*

Cor. Petals ſix, oblong, obtuſe; the three outermoſt looſely ſpreading, concave, equal; the three innermoſt about half as long, parallel, emarginate, ſtriated. *Stam.* Filaments ſix, inſerted into the ſummit of the germen, capillary, equal, very ſhort; anthers oblong, cohering, taper-pointed, opening by two pores. *Piſt.* Germen inferior, globoſe; ſtyle thread-ſhaped, longer than the ſtamens; ſtigma ſimple. *Peric.* Capſule nearly globoſe, with three blunt angles, of three cells and three valves. *Seeds* ſeveral, globoſe.

Eſſ. Ch. Corolla ſuperior, of ſix petals; the three innermoſt ſhorteſt, emarginate. Stigma ſimple.

1. G. *nivalis.* Linn. Sp. Pl. 413. Engl. Bot. t. 19. Jacq. Auſtr. t. 313. The common ſnow-drop is the only ſpecies of this genus. It grows wild in rather mountainous or rocky places in Germany, Italy, and other parts of the ſouth of Europe, flowering in the early ſpring. Whether it be truly wild in England is much to be doubted. In gardens the flowers are often double, from a multiplication of the inner petals, which are elegantly ſtreaked with a glaucous green. Mrs. Barbauld has beautifully deſcribed this favourite harbinger of ſpring in the following terms.

"As Flora's breath, by ſome transforming power,
Had changed an icicle into a flower,
Its name and hue the ſcentleſs plant retains;
And Winter lingers in its icy veins."

GALANTHUS, in *Gardening*, comprehends a plant of the bulbous rooted flowering perennial kind, of which the ſpecies is the common ſnow-drop (G. nivalis). It has two varieties, one with ſemi-double, and the other with double flowers. The common ſort comes firſt into flower.

Method of Culture.—All the ſorts of theſe ſmall beautiful plants are capable of being increaſed with little trouble, ſimply by ſeparating and planting out the off-ſets from the old roots, in the latter end of ſummer, as ſoon as their leaves begin to decay, or very early in the autumn, in the ſituations where they are to remain. Care ſhould however be taken that ſuch off-ſets be not taken off more frequently than about once in three or four years. The planting muſt conſtantly be performed in large bunches containing a great number of bulbs, in order that they may produce the better effect when in blow. The different ſorts ſhould be carefully intermixed. They are well ſuited to the fronts of borders, clumps, and ſhady plantations, producing a fine appearance when in flower, which is at a very early period.

GALAPAGAR, in *Geography*, a town of Spain, in New Caſtile; ſix miles E. of Eſcurial.

GALAPAGOS, or TORTOISE *iſles*, a cluſter of deſert iſlands in that part of the Pacific ocean, called by De Broſſes Polyneſia. Theſe iſlands have alſo been denominated the "Enchanted iſlands;" the largeſt being Maſcarin and Tabaco. They are all deſert, though ſituated in a delicious and fertile climate. The largeſt may be 10 Spaniſh leagues or 40 Britiſh miles in length, and 6 leagues in breadth; and they are ſeparated by many channels capable of receiving large veſſels. Capt. Dampier, in the 1ſt volume of his "Voyage round the World," has given the following account of them. The Galapagos are a great number of uninhabited iſlands, lying under, and on both ſides of the equator. The eaſternmoſt of them are about 110 leagues from the Main. They are laid down in the longitude of 181°, reaching to the weſtward as far as 176°, ſo that their longitude from England weſtward is about 68 degrees. Dampier, however, thinks that our hydrographers do not place them far enough to the weſtward. The Spaniards, who firſt diſcovered them, and in whoſe draughts alone they are laid down, report them to be a great number ſtretching N.W. from the line, as far as 5° N.; but Dampier did not ſee above 14 or 15. They are ſome of them, he ſays, ſeven or eight leagues long, and three or four broad. Capt. Vancouver, who paſſed through theſe iſlands without danger or obſtruction, obſerved that they lie from each other N.W. and S.E. at a diſtance of 21 miles, and that the ſouthernmoſt (S. lat. 1° 22'. E. long. 268° 18') did not appear to be above four miles in circumference, and the northernmoſt about a mile and a half. They are of a good height, moſt of them flat and even at the top; four or five of the eaſternmoſt are rocky, barren, and hilly, producing neither tree, herb, nor graſs, except ſome ſhrubs on the ſhore. In theſe iſlands there is water among the rocks in ponds and holes. Some others of theſe iſlands are moſtly plain and low, and the land more fertile, producing trees of different ſorts. Some of the weſternmoſt of theſe iſlands are nine or ten leagues long, and ſix or ſeven broad; the mould deep and black. Theſe produce large and tall trees, eſpecially mammee-trees, which grow in extenſive groves. In theſe large iſlands there are rivers of conſiderable ſize; and in many of the other leſſer iſlands there are brooks of good water. The Spaniards, when they firſt diſcovered theſe iſlands, found a multitude of guanoes, and land-turtle or tortoiſe, and hence named them the Galapagos iſlands. Dampier adds that he thinks no place in the world ſo plentifully ſtored with theſe animals.

GALAPHA, in *Ancient Geography*, a town of Mauritania Tingitana. Ptolemy.

GALARDIA, in *Botany*. See VIRGILIA.

GALARED, in *Geography*, a town of Sweden, in the province of Blekingen; 28 miles N. of Halmſtadt.

GALARIA, in *Ancient Geography*, a town of the iſland of Sicily.

GALARIPS, in *Botany*, a name originally given by Fred. Allamand to the fine South American plant, which Linnæus publiſhed by that of *Allamanda cathartica*.

GALARS, in *Geography*, a town of Tranſylvania; 16 miles S.E. of Hungad.

GALASA, in *Ancient Geography*, a town of Cœleſyria. Pliny.

GALASHIELS, in *Geography*, a flouriſhing little town of Scotland, in the county of Selkirk, on a ſmall river called Gala water, at its union with the Tweed. This town and its environs have long been famous for the manufacture of coarſe woollen cloth called "Galaſhiels grey," of which 50,000 yards have been made annually. The mode of huſbandry alſo in this neighbourhood has been much commended; five miles N. of Selkirk. N. lat. 55° 38'. W. long. 2° 53'.

GALASO, a river of Naples, which runs into the ſea near Tarento.

GALATA, a ſuburb of *Conſtantinople*, which ſee. See alſo PERA.

GALATA, a ſmall iſland in the Mediterranean, near the coaſt of Tunis. N. lat. 38° 15'. E. long. 9° 30'.

GALATEA, in *Mythology*, a ſea nymph, the daughter of Nereus and Doris, thus called on account of the fairneſs and beauty of her complexion. Ovid and Theocritus repreſent Polyphemus, the moſt celebrated of the Cyclops, as in love with Galatea, and the rival of Acis; and that this hideous giant buried the young prince under a rock, and the gods transformed him into a river, or rather into a river-god. Some authors, however, are of opinion, that Acis was a young prince of Sicily, who was in love with the beauteous Galatea; and that in deſpair he threw himſelf into the river, which from that time has borne his name. See NEREIDS and NYMPH.

GALATEO, in *Geography*, a town of Naples, in Calabria Ultra; eight miles E.S.E. of Nicotera.

GALATHEA, in *Natural Hiſtory*, a genus of cruſtacea in the Fabrician ſyſtem, including the Linnæan ſpecies of cancri ſtrigoſus, branchiatus, gregarius, and amplectens. The character of this Fabrician genus conſiſts in having the antennæ of unequal length, the anterior ones pedunculate; poſterior ſeſſile with the laſt joint ſetaceous; tail foliaceous. See article CANCER.

GALATI, a town of the iſland of Sicily, in the valley of Demona; 12 miles S. W. of Patri.

GALATIA, or GALLO-GRÆCIA, in *Ancient Geography*, a province of Aſia Minor, bounded on the E. by Cappadocia, on the W. by Bithynia, on the ſouth by Pamphylia, and on the N. by the Euxine ſea. The Gauls having invaded Aſia Minor in ſeveral bodies, of which Pauſanias (Attic. c. 4.) has given an account, conquered this country, ſettled in it, and called it Galatia, which in Greek ſignifies Gaul, or rather, perhaps, New or Little Gaul. The Gauls were denominated by the Greeks "Celtes" or "Galatæ."

It is not eaſy to aſcertain the epoch of their eſtabliſhment in Galatia. At the death of Alexander, however, in the year 323 B. C. we find that the Gauls of Thrace and Illyria were diſpoſed to join the confederacy of Greece againſt Macedonia; and that they aided Antigonus in the victory which he obtained over Antipater (321 B. C.). Theſe Gauls being afterwards attacked by Caſſander, the ſon of Antipater, and being obliged to retire to mount Hæmus (316 B. C.), were engaged anew in the ſervice of Antigonus by the grant of a conſiderable tract of country to be occupied by themſelves and their families. On this occaſion they extended themſelves into Aſia Minor, and became populous and powerful. This firſt invaſion of Aſia by thoſe Gauls, who attached themſelves to Antigonus, was followed by another ſome time afterwards under the command of Brennus. At the commencement of the campaign Leonorix and Lutarix, otherwiſe denominated Leonorius and Lutarius, ſeparated from him with a body of 20,000 men; and having entered Thrace, made themſelves maſters of the coaſt of the Propontis, and advanced to the Cherſoneſus and the Helleſpont. After having ſurmounted many obſtacles, Lutarix ſucceeded in his progreſs to Aſia; and Leonorix, in order to expedite the paſſage of his troops thither, formed an alliance with Nicomedes, king of Bithynia, who furniſhed him with veſſels for this purpoſe, and enabled him to obtain in that country a conſiderable eſtabliſhment (279 B. C.) Lutarix and Leonorix, who had for ſome time conducted ſeparate expeditions, became again united in this treaty with Nicomedes; and concurred not only in accompliſhing the deſigns of Nicomedes, but in making conqueſts on their own account. About the ſame time Attalus I., king of Pergamus, aſſigned a conſiderable territory to thoſe Gauls who ſerved againſt Antiochus; and it ſeems to have been about this period (278 years B. C.) that they eſtabliſhed themſelves in Aſia Minor. Upon the whole we may obſerve, that theſe ſeem to have been the principal epochas, to which we may refer the paſſage of the Gauls into Aſia. The firſt was that in which the country occupied by the Galatæ or Gauls comprehended only that part of the Helleſpont which was ceded to Leonorix and Lutarix. The ſecond was that in which Attalus (in the year 220 B. C.) aſſigned them a territory in Aſia Minor; and the third was that in which Galatia, ſeparated from the Helleſpont by Epictetus, became extended from the weſt towards the eaſt, or from Phrygia Major to Pontus Polemaicus. Accordingly the firſt eſtabliſhments of the Galatæ were towards the Ægean ſea; in proceſs of time they extended themſelves to mount Taurus; afterwards they obtained a more permanent eſtabliſhment, and gave the name of Galatia to the whole country which extended from the river Sangarius to the Halys.

The preciſe limits of Galatia are not eaſily aſcertained; as they have been various at different periods and variouſly aſſigned by different authors. The extent given to this country by Ptolemy, and ſtated in the beginning of this article, is generally allowed to be much too conſiderable, as it would comprehend the whole of Phrygia, Piſidia, and Lycaonia, and alſo the whole of Paphlagonia. The Galatæ who occupied it were diſtributed into three diviſions of people, each diviſion including others of a ſubordinate kind; theſe were the Tectoſagi, the Trocmi, and the Toliſtoboges or Toliſtoboii. M. d'Anville places the latter to the weſt, the Tectoſagi towards the middle bearing northward, and the Trocmi towards the eaſt. Pliny informs us that Galatia was divided into 195 tetrarchies. From Strabo we learn, that each of the three diviſions of the people already mentioned was divided into four cantons, each of which had a tetrarch; and beſides theſe 12 tetrarchs, there was a general council of the nation, compoſed of 300 ſenators. The tetrarchs were, as ſome ſay, hereditary, but, according to others, elective; but in proceſs of time they underwent a variety of changes. Strabo ſays, that they were at firſt reduced to three, then to two, and at laſt to one, which comprehended all the others, and which was poſſeſſed by Dejotarus. The laſt tetrarch and king of Galatia was Amyntas, who from being ſecretary to Dejotarus I., was made king of Piſidia in the year of Rome 714, and in 718, Marc Antony made him tetrarch of Galatia. After the death of Amyntas, Galatia was ranked by Auguſtus among the Roman provinces, and ſubjected to a proprætor, together with part of Phrygia, Piſidia, &c. but the three principal claſſes of people, above enumerated, retained their peculiar denomination and form of government. The adminiſtration of proprætors continued till the reign of Theodoſius the Great, or of Valens; and under the Chriſtian emperors it was divided into two provinces; Galatia Prima being ſubject to a conſul, and Galatia Secunda or Salutaris to a preſident. The former was ſituated towards the eaſt, contained ſeven towns, and had for its metropolis Ancyra; the ſecond lay to the weſt, and contained nine towns, the capital being Peſſinonte. The religion of the ancient Galatæ was blended with much ſuperſtition; and they are ſaid to have worſhipped the mother of the gods under the name of Agdiſtis. They offered human ſacrifices, devoting to this purpoſe the priſoners whom they took in war. They were a tall and valiant people; their arms were uſually a ſword and buckler, and they commonly fought naked. The impetuoſity of their attack was irreſiſtible, and almoſt always made them victorious. Although the Galatians have been ſometimes reckoned ſtupid and barbarous, it appears, from the teſtimony of different authors, that they applied to eloquence, and that they were fond of muſic. They had a particular inſtrument, which was called "Carnyx." They uſed the bath, and have been commended for their chaſtity and conjugal fidelity. They had ſplendid repaſts and feaſts, in which they covered their tables with bread and fleſh; and theſe ſorts of feſtivals were terminated on the part of the rich by the diſtribution of corn.

It appears from the acts of the apoſtles, that Paul preached ſeveral times in Galatia; firſt, A. D. 51 (Acts, xvi. 6); afterwards, A. D. 54 (Acts, xviii. 23.); and that he

he formed conſiderable churches in this province. He was probably the firſt who preached there to the Gentiles; although it is not unlikely, that Peter had preached there to the Jews, ſince his firſt epiſtle is directed to the Jews, ſcattered throughout Pontus, Galatia, &c. And the Jews converted by Peter probably occaſioned thoſe differences among the Galatian converts, which induced the apoſtle Paul to write his epiſtle, in which he takes pains to eſtabliſh his character of an apoſtle, which had been diſputed by ſome, with a view of placing him below Peter, who preached, generally, to the Jews only, and obſerved the law. For the date and purport of this epiſtle, ſee EPISTLE.

GALATOLA, in *Geography*, a town of Naples, in the province of Otranto; four miles E. S. E. of Nardo.

GALAVA, in *Ancient Geography*, a town of Great Britain, in the 10th rout of Antonine, ſuppoſed to be Old-Town, between Glanoventa or Lancheſter, in the county of Durham, and Alone or Whitley caſtle.

GALAX, in *Botany*, from γαλα, *milk*, on account of the whiteneſs of the flowers. Mitchel, who ſent it to Linnæus, named it *Viticella*, the application of which is not very obvious. Linn. Gen. 109. Schreb. 151. Willd. Sp. Pl. v. 1. 1146. Mart. Mill. Dict. v. 2. Juſſ. 420. (Solenandria; Vent. Malm. 69. Blandfordia; Fraſer in Andr. Repoſ. 343. Erythrorrhiza; Michaux Boreal-Amer. v. 2. 35.)—Claſs and order, *Pentandria Monogynia*. Nat. Ord. uncertain, Juſſ. *Ericæ*, Michaux.

Gen. Ch. *Cal.* Perianth inferior, in five deep, equal, acute ſegments, permanent. *Cor.* Petals five, lanceolate, oblong, equal, notched at the ſummit, ſlightly cohering at the baſe. Nectary tubular, of one leaf, half as long as the petals, in ten ſegments at the top, five of which are dilated, and five alternate ones ſhorter, the latter bearing the anthers. *Stam.* Filaments ſcarcely any; anthers five, nearly ſeſſile on the inner ſurface of the ſhorter ſegments of the nectary. *Piſt.* Germen ſuperior, ovate; ſtyle none; ſtigma fleſhy, of three or four lobes. *Peric.* Capſule of three cells and three valves. *Seeds* numerous, minute.

Eſſ. Ch. Calyx in five deep ſegments. Petals five. Nectary tubular, in ten ſegments, alternately bearing the anthers. Capſule ſuperior, of three cells and three valves. Seeds many.

1. G. *aphylla*. Linn. Sp. Pl. 289. Curt. Mag. t. 754. (Solenandria cordifolia; Vent. Malmais. t. 69. Blandfordia cordata; Andr. Repoſ. t. 343. Erythrorrhiza rotundifolia; Michaux Boreal. Am. v. 2. 35. t 36.)—Native of mountainous places in Georgia and Carolina, flowering in May. Mr. Fraſer firſt brought it to England. The *root* is perennial, compoſed of very red fibres. *Stem* none. *Leaves* radical, heart-ſhaped, doubly crenate, ſmooth, on very long foot-ſtalks. *Flowers* numerous in long-ſtalked ſpikes, reſembling thoſe of a *Clethra*. The Linnæan generic deſcription, chiefly communicated by Mitchel, is ſo very erroneous, that it is no wonder none of the botaniſts who ſaw the plant could determine it, nor could the *Galax* of Linnæus ever have been certainly aſcertained, but by his herbarium, where original ſpecimens are preſerved.

GALAXIA, from γαλα, *milk*, though the application ſeems not very evident, and the name is, beſides, too near *Galax*. Thunb. Nov. Gen. 50. Schreb. 451. Willd. Sp. Pl. v. 3. 583. Juſſ. 57. Mart. Mill. Dict. v. 2. Cavan. Diſſ. 340. Lamarck Illuſtr. t. 568. Gawler in Curt. Mag. 1208. Claſs and order, *Monadelphia Triandra*. Nat. Ord. *Enſatæ*, Linn. *Irides*, Juſſ.

Gen. Ch. *Cal.* Spatha of one or two membranous cloſed leaves. *Cor.* of one petal, ſuperior; tube long, thread-ſhaped, erect, ſlightly dilated at the top: limb in ſix deep regular, obovate, obtuſe, ſpreading ſegments; the three outermoſt having each a nectariferous cavity at its baſe. *Stam.* Filaments three, united into a tube; anthers ovate. *Piſt.* Germen inferior, ſtalked, obtuſely triangular, ſmooth; ſtyle thread-ſhaped, rather longer than the ſtamens; ſtigmas three, divided into numerous ſpreading capillary ſegments, almoſt to their baſe. *Peric.* Capſule oblong, nearly cylindrical, with three furrows, three cells, and three valves. *Seeds* numerous, ſmall, globoſe.

Eſſ. Ch. Spatha of one or two leaves. Corolla regular, of one petal, in ſix deep ſegments, with an elongated tube. Style one. Stigmas three, in numerous capillary ſegments. Capſule inferior, of three cells. Seeds globoſe.

This is a Cape genus, firſt eſtabliſhed by Thunberg, and moſt allied to *Siſyrinchium*. Only two or three ſpecies are known, which are of a diminutive ſtature. G. *ovata* (*Ixia Galaxia*; Linn. Suppl. 93) is figured in Curt. Mag. t. 1208. Andr. Repoſ. t. 94. Jacq. Ic. Rar. t. 291. The *leaves* are ovate and ſhort. *Flowers* occaſionally yellow or purple, very fugacious—G. *graminea*, (*Ixia fugaciſſima*; Linn. Suppl. 94), Curt. Mag. t. 1292, Jacq. Coll. v. 2. 366. t. 18. f. 2, differs chiefly in having narrow linear *leaves*. This genus appears to occupy the ſame ſituations on graſſy hillocks at the Cape of Good Hope, as *Ixia Bulbocodium* does in the ſouth of Europe, with which plant it alſo agrees in general aſpect, as well as in the variable colour and ſize of the bloſſoms. The ſpecies require the ſame treatment as other Cape bulbs, and flower with us in the ſpring.

GALAXIA, in *Mythology*, a feſtival in honour of Apollo, ſo called becauſe they offered in it to that god a ſort of furmety, of barley and milk.

GALAXY, in *Aſtronomy*, the name given to that remarkable zone of light which forms nearly a great circle of the celeſtial ſphere, and which is by us called the *milky way*. It cuts the ecliptic near the two ſolſticial points, and is inclined to it about 60°. It traverſes the conſtellations Caſſiopea, Perſeus, Auriga, part of Orion, Gemini, the Great Dog, and the Ship, where it appears moſt reſplendent in ſouthern latitudes; it then paſſes through the feet of the Centaur, the Croſs, the ſouthern Triangle, and returns towards the north by the Altar, the tail of the Scorpion, the arc of Sagittarius; it then divides into two branches, paſſing through Aquila, Sagitta, the Swan, Serpentarius, and the head of Cepheus, and returns to Caſſiopea. This path is deſcribed in the poem of Manilius, who appears to have been very fortunate in his conjecture as to the cauſe of this light:

> "Anne magis denſâ ſtellarum turba coronâ
> Contexit flammas et craſſo lumine candet
> Et fulgore nitet collato clarior orbis?"

Ariſtotle, almoſt always miſtaken when he gives an opinion on ſubjects of natural philoſophy, ſuppoſes the milky way to be a luminous meteor placed in the middle regions.

Aſtronomers have for a long time been diſpoſed to attribute this phenomenon to a great aſſemblage of ſtars; but the queſtion was firſt put out of doubt by Dr. Herſchel, who completely reſolved the whole maſs into ſeparate ſtars: he has counted 50,000 in a ſpace 15 long by 2 broad.

This, however, is far from ſatisfying the curioſity of philoſophers; an intereſting queſtion immediately ariſes: Why ſhould there be ſuch a zone of ſtars, and what explanation does it admit of? Dr. Herſchel is undoubtedly the aſtronomer who has taken the moſt pains in this inveſtigation, and his theory is extremely plauſible, at leaſt, if not entirely ſatisfactory. He ſuppoſes the ſidereal univerſe to be diſtributed,

into nebulæ and cluſters of ſtars, and the milky way to be that particular cluſter in which our ſun is placed. Under *Nebulæ*, we ſhall enter further into this theory; at preſent we ſhall only add a ſhort extract, in Dr. Herſchel's own words, from the Tranſactions of 1784.

"It is very probable, that the great ſtratum called the milky way, is that in which the ſun is placed, though perhaps not in the very centre of its thickneſs. We gather this from the appearance of the galaxy, which ſeems to encompaſs the whole heavens, as it certainly muſt do if the ſun was in the ſame. For, ſuppoſe a number of ſtars arranged between two parallel planes, indefinitely extended every way, but at a conſiderable diſtance from each other; and calling this a ſidereal ſtratum, an eye placed ſomewhere within it will ſee all the ſtars in the direction of the planes of the ſtratum, projected into a great circle, which will appear lucid on account of the accumulation of the ſtars; while the reſt of the heavens, at the ſides, will only ſeem to be ſcattered over with conſtellations more or leſs crowded, according to the diſtance of the planes, or number of ſtars contained in the thickneſs or ſides of the ſtratum.

"Thus in *fig.* 114. *Plate* XIII. *Aſtronomy*, an eye S, within the ſtratum *a b*, will ſee the ſtars in the direction of its length *a b*, or height *c d*, with all thoſe in the intermediate ſituations projected into the lucid circle A B C D, while thoſe in the ſides *m v*, *n w* will be ſeen ſcattered over the remaining part of the heavens at M V N W.

"If the eye were placed ſomewhere without the ſtratum, at no very great diſtance, the appearance of the ſtars within it would aſſume a form of one of the leſs circles of the ſphere, which would be more or leſs contracted to the diſtance of the eye; and if this diſtance were exceedingly increaſed, the whole ſtratum might at laſt be drawn together into a lucid ſpot, of any ſhape, according to the poſition, length, and height of the ſtratum.

"Let us now ſuppoſe, that a branch or ſmaller ſtratum ſhould run out from the former, in a certain direction, and let it alſo be contained between two parallel planes extended indefinitely onwards, but ſo that the eye may be placed in the great ſtratum ſomewhere before the ſeparation, and not far from the place where the ſtrata are ſtill united. Then will this ſecond ſtratum not be projected into a bright circle, like the former, but will be ſeen as a lucid branch, proceeding from the firſt, and returning to it again, at a certain diſtance, leſs than a ſemicircle.

"Thus, in the ſame figure, the ſtars in the ſmall ſtratum, *p q*, will be projected into a bright arch at P R R P, which, after its ſeparation from the circle C B D, unites with it again at P.

"What has been inſtanced in parallel planes, may eaſily be applied to ſtrata irregularly bounded and running in various directions; for their projections will of conſequence vary according to the quantities of the variations in the ſtrata and the diſtance of the eye from the ſame.

"And thus any kind of curvatures, as well as various different degrees of brightneſs, may be projected in the projections. From appearances, then, as I obſerved before, we may infer that the ſun is moſt likely placed in one of the great ſtrata of the fixed ſtars, and very probably not far from the place where ſome ſmaller ſtratum branches out from it. Such a ſuppoſition will ſatisfactorily, and with great ſimplicity, account for all the phenomena of the milky way, which, according to this hypotheſis, is no other than the appearance of the projection of the ſtars contained in this ſtratum and its ſecondary branch. As a farther inducement to look on the galaxy in this point of view, let it be conſidered, that we can no longer doubt of its whitiſh appearance ariſing from the mixed luſtre of the numberleſs ſtars that compoſe it. Now ſhould we imagine it to be an irregular ring of ſtars, in the centre nearly of which we muſt then ſuppoſe the ſun to be placed, it will not appear a little extraordinary, that the ſun, being a fixed ſtar, like thoſe that compoſe this imagined ring, ſhould juſt be in the centre of ſuch a multitude of celeſtial bodies without any apparent reaſon for this ſingular diſtinction; whereas, on our ſuppoſition, every ſtar in this ſtratum, not very near the termination of its length and height, will be ſo placed, as alſo to have its own galaxy, with only ſuch variations in the form and luſtre of it as may ariſe from the particular ſituation of each ſtar."

In the year 1785, Dr. Herſchel continued his inveſtigations of the form of this ſtratum, and was enabled to give a figure of what he conceived to be a ſection of it. This is repreſented, *fig.* 115. If the celeſtial globe be adjuſted to 55°, and σ Ceti be brought to the meridian, it will have the plane of this ſection pointed out by the horizon. The moſt diſtant ſtar is ſuppoſed to be about 500 times farther from the ſun than Sirius. Light would take 20,000 years to traverſe the whole extent. The interior circle is about 40 times the diſtance of Sirius.

GALBA, SERVIUS SULPICIUS, in *Biography*, a Roman emperor, was conſul under Tiberius, A. D. 33. Caligula gave him the command of the legions in Upper Germany, and with theſe he reſtored the ancient military diſcipline, and repreſſed the inroads of the natives. Upon the death of that emperor, he was urged by his friends to aſſume the imperial authority; but he choſe rather to ſubmit to the government of Claudius, who continued him in his command, and conferred upon him the proconſulate of Africa. In this high office, he conducted himſelf with the greateſt propriety, and his victories were gratified by a public triumph. He afterwards paſſed ſeveral years as a private citizen, till he was nominated by Nero in 61 to the government of a province in Spain. In 68 he was declared emperor, and the death of Nero immediately followed. The new reign was full of troubles, and perſons were found who were perpetually plotting againſt the power of Galba. He puniſhed with great ſeverity all whom he ſuſpected as inimical to his government, and gave his confidence to perſons of bad character. He retained his love of juſtice, but his rigour in various inſtances was carried to the bounds of cruelty; while in others, avarice and favour procured impunity to the moſt guilty. Virtue was, however, predominant in his mind; and the principal cauſe of his ſubſequent fate was a ſentiment worthy of a ſovereign: when urged to beſtow largeſſes upon the ſoldiery, he ſaid, "I have been accuſtomed to levy ſoldiers, not to buy them;" a ſentence which they never forgot. Galba, finding himſelf in difficulties that might probably end in ſome fatal diſaſter, reſolved to adopt a ſucceſſor, and his choice fell upon Piſo Licinianus, a perſon of illuſtrious birth, and of ſtrict moral conduct. The ſenate approved the adoption; but Otho, who laid claim to the honour, immediately began to excite a conſpiracy againſt him. The plan ſucceeded, a revolt broke out, and Otho was declared emperor. Galba attempted to rally his forces, but it was now too late; he was univerſally abandoned, and diſpatched by a multitude of wounds. Such was the miſerable end of this emperor, who was ſlain in the ſeventy-third year of his age, and in the ſeventh month of his reign. The virtues which had ſhone ſo bright in Galba, when in a private ſtation, in many inſtances totally diſappeared when he aſcended the throne; and he who ſhewed himſelf the moſt impartial judge, forgot the duties of an emperor. He is one of many who would have been judged worthy of a crown had he never worn one.

Galba was the laſt emperor who claimed deſcent from the ancient families of Rome.

GALBÆ CASTRUM, or *fortreſs of Galba*, in *Ancient Geography*, a town of Africa, in Numidia.

GALBANETUM, a compoſition, or preparation, of galbanum, formerly preſcribed, but now much out of uſe.

GALBANUM, in *Pharmacy*, a gum, ſuppoſed by Linnæus to iſſue from an inciſion in the root of a ferulaceous plant, called, in Latin, *ferula galbaniflua*, growing in Arabia, Syria, Africa, &c. The word is derived, according to Martinius, from the Hebrew *chelbenah*, *fat*. It is highly probable, that galbanum is obtained from different ſpecies of the Bubon, partly by its ſpontaneous exudation from the joints of the ſtem, but more generally, and in greater abundance, by making an inciſion in the ſtalk a few inches above the root, from which it immediately iſſues, and ſoon becomes ſufficiently concrete to be gathered. For an account of its properties and uſes, ſee BUBON *galbanum*. The compound pills of galbanum are prepared in the following manner: Take of galbanum gum-reſin an ounce, myrrh and ſagapenum, of each 1½ ounce, aſſafœtida gum-reſin half an ounce, and as much ſyrup as is ſufficient. Beat them together till they form an uniform maſs. The doſe is from gr. x. to 3ſs.

The beſt way of purifying it is to include it in a bladder, and keep it in boiling water, till it becomes ſoft enough to be ſtrained, by preſſure, through a hempen cloth: its eſſential oil will be thus preſerved, which is carried off in evaporation both by water and ſpirit. The eſſential oil of galbanum, diſtilled with water, riſes to the ſurface, of a yelloviſh colour, and in quantity about the 20th part of its weight. The empyreumatic oil is of a blue colour, and changes in the air into purple.

The galbanum colour was a prevailing faſhion with the Romans.

"Reticulumque comis auratum ingentibus implet,
Cærulea indutus ſcutulata, aut galbana raſa."
Juvenal, Sat. ii. l. 96.

And Martial, ſpeaking of an effeminate perſon, ſays,

"Galbanos habet mores." Lib. i. Epig. 97.

Commentators differ about the colour of "galbana raſa;" but the galbanum flower is deſcribed to be of a greeniſh yellow. See BUBON.

GALBULA, in *Ornithology*, the name of a bird of the thruſh kind, common in Italy and Germany, very remarkable for the elegant ſtructure and hanging of its neſt; and thence called by ſome *picus nidum ſuſpendens*, and by others *oriolus*, *chlorus*, and *icterus*, being ſuppoſed to be the icterus or jaundice-bird of Pliny, and the old writers. This bird, the loriot of Buffon, the witwall of Willughby, the golden thruſh of Edwards, and golden oriole of Latham, &c. &c. is ſomewhat larger than the common thruſh: its beak is a finger's breadth long, and red; its wing-feathers are black, but ſome are tipped, and others edged with white; others are varied with yellow, and the reſt are an extremely bright and beautiful yellow. The female is leſs beautiful, the yellow being more ſhaded with black and brown. The galbula feeds on inſects, and is in moſt places very much eſteemed at the table, but is no where to be had at all ſeaſons, being a bird of paſſage. See ORIOLUS *Galbula*.

GALBULA is alſo a ſpecies of the *Alcedo*; which ſee.

GALDER, in *Geography*, a town of the iſland of Canary.

GALDETOOR, a town of Hindooſtan, in the circar of Cicacole; 36 miles W. S. W. of Viſigapatam.

GALDHEIM, a town of Germany, in the principality of Wurzburg; ſeven miles E. of Schweinfurt.

GALE, THOMAS, in *Biography*, was born in 1507; and educated under Richard Ferris, afterwards ſerjeant-ſurgeon to queen Elizabeth. He was ſurgeon in the army of king Henry VIII. at Montruil, in 1544; and alſo in that of king Philip at St. Quintin, in 1557. He afterwards ſettled in London, and became very eminent in the practice of ſurgery. He was living in 1586. Biſhop Tanner gives the following liſt of his writings: "The Inſtitution of a Chirurgeon." "An Enchiridion of Surgery," in four books. "On Gun-ſhot wounds." "Antidotarie," in two books. All theſe were printed together, London, 1563, 8vo. "A compendious Method of curing præternatural Tumours." "On the Several Kinds of Ulcers, and their Cure." "A Commentary on Guido de Cauliaco." "An Herbal, for the Uſe of Surgeons." "A brief Declaration of the worthy Art of Medicine, and the Office of a Chirurgeon." "An Epitome of Galen de natural. Facultat." The two laſt were printed with a tranſlation of "Galen de Methodo Medendi." Numerous complaints of the intruſion of illiterate pretenders and empirics into the practice of medicine and ſurgery are interſperſed through theſe tracts; ſome of which are worth notice, as containing curious information reſpecting the ſtate of the profeſſion at that time. Aikin, Biog. Mem. of Med.

GALE, THEOPHILUS, was born at Kings Teinton in Devonſhire in the year 1628. The early parts of his education he received under the roof of his father's houſe, who was vicar of the pariſh; he was afterwards ſent, for improvement, to a grammar ſchool in the neighbourhood, and in the year 1647 he was entered at Magdalen college, Oxford. In 1649 he was admitted to the degree of B. A. before he had attained the uſual ſtanding, at which, according to the ſtatutes of the univerſity, that degree is conferred; and in the following year he was the ſucceſsful candidate for a fellowſhip in his college. In 1652 he took his degree of M. A., became an eminent tutor, and likewiſe a diſtinguiſhed preacher. While he diſcharged the ſeveral duties connected with theſe functions, he applied himſelf to theological ſtudies, and was aſſiduous in collecting materials for his great work, publiſhed many years afterwards under the title of "The Court of the Gentiles." The plan of this publication was laid in early life, upon the firm conviction that it might be made to appear that "the wiſeſt and moſt eſteemed of the pagan philoſophers borrowed the moſt rational of their ſentiments, and were indebted for their moſt ſublime contemplations, from the Scriptures; ſo that how different ſoever they might be in their appearance, not only their theology, but their philoſophy and philology were derived from the ſacred oracles." To the accompliſhment of this plan he devoted a conſiderable portion of many of the beſt years of his life, though he was never negligent of thoſe duties incumbent upon him in the other characters which he ſuſtained. In 1657 he ſettled as a ſtated preacher at Wincheſter, where he acquired univerſal eſteem by his miniſterial ſervices, and by his exemplary life and converſation. Upon the paſſing of the Act of Uniformity, Mr. Gale found himſelf compelled to reſign his living, and he was at the ſame time deprived of his fellowſhip. Under theſe circumſtances, he undertook the tuition of the ſons of lord Wharton, with whom he went to Caen in Normandy, where there was a celebrated ſeminary of learning, under the direction of the moſt diſtinguiſhed profeſſors of the reformed religion in France. In 1665 he returned with his pupils to England, and reſided with them, till September in the following year, at their father's ſeat in Buckinghamſhire. On the firſt of that month he ſet out for
